The potato-mould is the *Peronospora infestans* Caspary, and were it not for its effects, would be regarded by every one of taste as a beautiful object. Were we flies or insects, which are so liberally endowed with sight and eyes, and quite unconcerned about the crops, the leaves of the potatoes would be quite a pretty set of objects to investigate, presenting handsome, white, many-branched, and beaded-twigged plants, with oval or egg-shaped seed bodies on the tips of each smaller branch. These vegetable growths issue from the breathing pores of the leaves, and, besides feeding themselves on the nutriment intended for the leaves, choke up the internal and external passages, and prevent the healthy action from being maintained. Soon the leaves become at first paler, or yellow; then discolored spots appear; then the stems are spotted with dark patches. Even the cellular tissue (or pulpy part of the stems or stalks, "potato-stalks" as we call them) is discolored, and filled with dark clotted substances; subsequently, sooner or later, the stalks putrefy, the skin separates from the harder or woody portions; next the tubers suffer, spots and decay appear in a more or less regular manner of concentric lines, the skin withers, a white mouldiness often occurs, especially if the potatoes lie in a moist place; the "rot" increases with fearful rapidity, the tuber has a disgusting odor, certain smaller insects help the process at this stage, and putrescence closes the scene.

A plant thus simple in its general structure, and capable of bearing on its rapidly growing branches three thousand two hundred and seventy (3,270) seed-like pods, each containing at least six seed-like bodies (*zoospores*) on one square line of the under surface of the leaves, and from each of which, in turn, a perfect seed-bearing "mould" is produced in eighteen hours, may be readily conceived to be capable, minute as it is, of incalculable mischief. The reader may, however, calculate, by reduction to fractions of an inch, the size of one of the seed-vessels (*acrospore*) containing these six or more seeds, when Prof. Caspary computes its breadth at 1-165 of a millimetre, and its length at 1-125 of a millimetre (*Monatsberichte der Konigl. Akademie, etc., fur Mai*, 1855). Seeds so minute can be readily absorbed by the roots, or even by the leaves, and in such abundance that the very atmosphere may be surcharged with them. A few of them placed in a drop of water and applied to the leaves, stems, and tubers, by Dr. DeBarry, produced, in a short time, brown spots, and eventually the disease.

The remedy or the prevention, what? Perhaps none, as yet discovered, which will be effectual; but the entire destruction by fire of all infected stalks and potatoes looks to a suggestive prevention. — J. L. RUSSELL: *American Naturalist.*

AGRICULTURAL ENGINEERING.

We notice in our foreign exchanges that a college in Scotland has recently decided to grant the titles of Bachelor and Master of Agriculture to those who shall pass a thorough examination in certain prescribed and appropriate branches of study, thereby raising agriculture to a recognized place among other industrial sciences, and giving to its educated practitioners the same prestige that belongs to similar practical professions. This may be considered a decided step toward a full recognition of the important truth that the extended introduction of machinery into farm operations, and the application of the principles of chemistry in the management and tillage of the soil, are producing what will constitute in reality a new department of engineering, a department including within its boundaries all those principles of mechanics embraced in the construction of farm apparatus and the structure of farm buildings, the nature of different soils, the requirements of different plants, and the reaction upon them and the ground on which they grow of mineral and organic manurial agents, and, not less than in any of these, requiring in its successful practitioner a full knowledge and correct appreciation of the possibilities and also the difficulties of introducing new motive forces in the place of those now employed in the operations of agriculture, and of the absolute necessity which often exists of materially modifying a class of machinery to suit the peculiar wants of different regions or districts. The conferring of the degrees above referred to does not, it is true, infer excellence in all of the points above indicated; but when the duties of the agricultural engineer become fully understood, as they may be twenty years hence, and his sphere becomes more exclusively his own, such, or even a more varied and extended, knowledge will be required at his hands, and if he properly fulfils his mission there will be fewer instances of such mistakes as those shown in the numberless attempts to produce a profitable steam-plough, in which agriculturists failed from their lack of knowledge of the mechanical art, and engineers succeeded no better because they knew little or nothing of the true requirements of the case, or of the trials to which the apparatus must be necessarily subjected in practice.

Among the problems the solution of which is most likely to be obtained at the hands of men specially educated for the prospective business or profession under consideration, the adaptation of steam to purposes of tillage holds a prominent but by no means all important place; as but slighlty secondary to this is the application of the steam, air, or some equivalent engine as a stationary motor for agricultural purposes; for, notwithstanding the multiplicity of portable steam-engines, there are as yet few or none which an unskilled attendant should feel safe in using. There might also be mentioned the production of compound machines for preparing by different changes of parts the food for animals, whether of grain or stalk or root; for disintegrating and preparing refuse mineral and vegetable substances for fertilizing purposes: for cleaning fields from stones; for the rapid and efficient construction of drains; and for many other purposes which would be developed in time, but can hardly be now foreseen.

We have thus briefly and hastily indicated the sphere

in which the agricultural engineer of the future will labor, when the unnumbered fag-ends of practical science that now help to make up the sum total of agricultural knowledge shall be fused and welded into a symmetrical whole, just as from the scattered and varying truths with which the millwright worked a hundred years ago has been formed the "mechanical engineering" of the present time. Although it may and probably will be a score of years before such a result will be even approximately reached, and even longer than this before men shall devote themselves wholly to its profession, there can be but little doubt that the time will sooner or later come when the practice of agriculture will require and secure the systematized employment of the highest grade of engineering skill. — *American Artisan.*

BONES FOR FOWLS. — Bones usually have attached to them a quantity of flesh and fat, which render them valuable. The fat enables the fowls to resist the cold; the flesh gives them muscle and material for the formation of eggs; the carbonate of lime furnishes egg-shells; and the phosphate yields materials for bones and for the tissues. A boy can, in a few minutes, chop up with a hatchet all the lesser bones that come from the table, and we regard them as very valuable. If we were to start a poultry establishment on a large scale, we should certainly make arrangements to procure all the fresh bones possible. It would not be difficult to devise a machine that would crack them into fragments the size of large beans, and we should get paid twice; first through the chickens, and secondly through the improved character of the manure. — *Farmer's Home Journal.*

A grindstone should not be exposed to the weather, as it not only injures the woodwork, but the sun's rays harden the stone so much, in time, as to render it almost useless; neither should it stand in the water in which it runs, as the part remaining in the water softens so much that it wears unequally and "out of true."

Boston Journal of Chemistry.

BOSTON, DECEMBER 1, 1868.

☞ Any one sending us the names of three subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For five subscribers we will send the Petite Microscope; for twenty-five we will send, in addition to the microscope, a copy of "Stockhart's Chemistry for Students," the best elementary treatise yet published; for one hundred subscribers we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stockhart's Chemistry.

☞ Physicians, students, clerks in drug-stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

Mr. B. R. DOWNES is Travelling Agent for the *Journal.*

We beg leave to call attention to the advertisement of Mr. George S. Chase in another column. An arrangement of this kind has long been needed.

We are almost daily in receipt of letters from correspondents at a distance, containing lists of articles which they wish us to purchase and forward to them. While we are always glad to be of service to our friends, we still find these commissions a serious tax upon our time, and we have at last concluded to turn them over to Mr. Chase, who has charge of the publishing department of the *Journal*, and who will make of this business a specialty; and we cordially recommend him to our friends, assuring them that any errands they may entrust to him will be carefully and speedily attended to.

Since the article upon burning-glasses was written, we learn that Mr. Parker, of London (presumably of the same house as the one mentioned), has just constructed another lens three feet in diameter, three inches thick in the centre, and weighing 212 pounds. We have seen no authentic statement of the results achieved by this lens, but shall look for them with great interest.

THE SOURCE OF THE SUN'S HEAT.

In a former article, on "The Origin of Force" [July number of the *Journal*], it was explained that all the varied forms of force which we see manifested in the physical world, with the single exception of the tidal wave, have their fountain-head in the *sun*. They are, in fact, nothing but transmuted sunbeams.

The amount of heat given out by the sun is enormous. Making allowance for that which is lost by absorption in passing through the atmosphere, it has been calculated that the heat received by the earth during a year would be sufficient to melt a layer of ice one hundred feet thick and covering the whole earth. But even this is but a small fraction of the heat actually given out by the solar orb. It must be borne in mind that the sun radiates heat into space in every other direction, as well as towards the earth. If, now, we imagine a hollow sphere to surround the sun, at the distance of the earth, our planet would cover only about $\frac{1}{2,300,000,000}$ of its surface. The sun, then, must radiate into space, 2,300,000,000 times as much heat as the earth receives. Sir John Herschel has calculated that if a cylinder of ice forty-five miles thick were darted into the sun with the velocity of light (about 190,000 miles a second), it might be melted by the heat radiated by the sun, without lowering the temperature of the sun itself.

What, then, is the source of this enormous amount of heat? Some have supposed that the heat is developed in the same way as in an ordinary fire; that is, that the materials of the sun are burning up, and thus producing the light and heat which it sends forth. And at first this theory appears very plausible. The sun is almost a million and a half times as large as the earth; and a body of such immense bulk might burn for centuries before it would be utterly consumed, or before its apparent size would be very much diminished. There are, however, no substances known to us which would produce so much heat for so long a time as we know the sun to have been shining. Carbon (of which the different kinds of *coal* are forms more or less pure) is one of the most combustible substances with which we are acquainted; but if the sun, large as he is, were a mass of pure carbon, and were burning at a rate sufficient to produce the light and heat which he is giving out, he would be wholly consumed in five thousand years. It is hardly possible, then, that the fires of the great central luminary of our solar system are kept up in this way which is so familiar to us.

A more satisfactory theory of the origin of the solar light and heat, and one which, with slight modifications, is adopted by the leading scientific men of our time, is known as the *meteoric* theory. It is sometimes spoken of as *Mayer's* theory, from its author, a German physician, who first published it in 1848.

In an article on the nature of force, in the June number of the *Journal*, we explained that a pound weight which has fallen through seven hundred and seventy-two feet, will, when its motion is arrested, generate a *unit of heat*, or, in other words, heat enough to raise the temperature of a pound of water one degree. A body falling that distance would acquire a velocity of about two hundred and twenty-three feet a second. Hence, a pound ball moving at the rate of two hundred and twenty-three feet a second, will produce a unit of heat when it is stopped in its course. We know, moreover, that the velocity with which a falling body strikes the ground is in proportion to the square root of the height from which it falls; that is, in order to double or treble its speed, a body must fall from four or nine times the height. A pound ball, then, moving at *twice* the speed of two hundred and twenty-three feet a second, will be able to generate *four* units of heat; one moving with *thrice* this speed, *nine* units of heat; and so on. If, therefore, we know the weight of a body, and the velocity with which it is moving, we can easily calculate how much heat will be generated on stopping it.

Now, the earth is moving in its pathway round the sun at the rate of more than sixty-eight thousand miles an hour, or more than one thousand miles every *minute*. It is also whirling round on its axis every twenty-four hours; so that a point on the equator turns more than a thousand miles an hour. If its motion were arrested, its elements would melt with fervent heat, and most of them would be converted into vapor. If the earth should fall into the sun, the heat generated by the shock would be sufficient to keep up the solar light and heat for *ninety-five years*. Luckily, we have no reason to fear that our planet is in any danger, at least for ages to come, of thus contributing to the "waning fires" of the King of Day. But that bodies are continually falling into the sun, we have every reason to believe. We know that countless swarms of meteors are revolving in spiral rings around the sun, and that they must eventually be drawn into that orb; and, from the velocity with which they must strike, it has been shown that they could fall in sufficient numbers to generate all the heat and light of the sun, without increasing his bulk enough to be detected, since accurate measures of his diameter were first made.

Such, in brief, is the *meteoric theory* of the origin of solar light and heat. First devised by Mayer, it was further developed, in 1854, by Prof. Thomson, who has published, in tabular form, the mathematical results of his investigations. Of some of these results, Prof. Tyndall remarks as follows, in the last edition of his lectures on "Heat Considered as a Mode of Motion:"—

"From the tables published by Prof. Thomson, I extract the following interesting data, firstly, with reference to the amount of heat equivalent to the rotation of the sun and planets round their axes — the amount, that is, which would be generated, supposing a brake applied at the surfaces of the sun and planets until the motion of rotation was entirely stopped; secondly, with reference to the amount of heat due to the sun's gravitation — the heat, that is, which would be developed by each of the planets in falling into the sun.

PLANETS.	Heat of Gravitation equal to Solar Emission for a period of		Heat of Rotation equal to Solar Emission for a period of	
	Years.	Days.	Years.	Days.
Sun	..	..	116	6
Mercury	6	214	..	15
Venus	83	227	..	99
Earth	94	303	..	81
Mars	12	252	..	7
Jupiter	32,240	..	14	144
Saturn	9,650	..	2	127
Uranus	1,610	..	..	71
Neptune . . .	1,890	..	..	..

"Thus, if the planet Mercury were to strike the sun, the quantity of heat generated would cover the solar emission for nearly seven years; while the shock of Jupiter would cover the loss of 32,240 years. The heat of rotation of the sun and planets, taken together, would cover the solar emission for 134 years; while the total heat of gravitation (that produced by the planets falling into the sun) would cover the emission for 45,589 years.

"Whatever be the ultimate fate of the theory here sketched, it is a great thing to be able to state the conditions which certainly would produce a sun; to be able to discern in the force of gravity, acting upon dark matter, the source from which the starry heavens *may* have been derived; for, whether the sun be produced and his emission maintained by the collision of cosmical masses or not, there cannot be a doubt as to the competence of the cause assigned to produce the effects ascribed to it. Solar light and solar heat lie latent in the force which pulls an apple to the ground. The potential energy of gravitation was the original form of all the energy in the universe. As surely as the weights of a clock run down to their lowest position, from which they can never rise again unless fresh energy is communicated to them from some source not yet exhausted, so surely must planet after planet creep in, age by age, towards the sun. When each comes within a few hundred thousand miles of his surface, if he is still incandescent, it must be melted and driven into vapor by radiant heat. Nor, if he be crusted over, and become dark and cool externally, can the doomed planet escape its fiery end. If it does not become incandescent, like a shooting star, by friction in its passage through his atmosphere, its first graze on his surface must produce a stupendous flash of light and heat. It may be at once, or it may be after two or three bounds like a cannon-shot ricochetting on a surface of earth or water; the whole mass must be crushed, melted, and evaporated by a crash, generating in a moment some thousands of times as much heat as a coal of the same size would produce by burning."

KEROSENE.

The error must not prevail, that kerosene oil of legal standard will ignite or burn if a lamp containing it is broken. Good oil, such as should be used in families, will *extinguish* flame when brought in contact with it. Oil heated to the usual point while burning in a lamp in the evening, should extinguish a lighted match when thrust into it. If the reader is using in his family unadulterated kerosene, he may take off the cap of the lamp, thrust in a lighted taper; he may turn it out upon the floor, and apply flame; and it will not take fire or explode. Standard kerosene, such as the law recognizes, is *perfectly safe.* We wish to state and re-state this fact, as it would be a great misfortune, especially to the poor, to have the erroneous idea prevail, that *all* kerosene is dangerous. A cheap light is too great a blessing to be deprived of through unjust prejudice. It is only the wretched adulterated oils, the naphtha fluids, that are dangerous.

We are almost discouraged in our efforts to explain the nature of the illuminating fluids, when we find, as we have during the past month, a daring, reckless fellow travelling through the towns about this city, selling recipes to make a cheap naphtha burning liquid. The discouragement does not arise from the fact that such adventurers are numerous, and attempt to deceive the people, but that they so easily *succeed* in their evil work. These frauds are not practised upon the uneducated alone, but upon the learned, the intelligent, — those who certainly ought not to be ignorant of the simplest facts in science. The recipe-peddler alluded to, succeeded in filching his dollar from lawyers, clergymen, a judge of a police court (who, instead of patronizing him, should have issued a warrant for his arrest), and many others who are reckoned among the educated classes. We have reason to think the country is full of these men, and our readers must be on their guard. Not only their own lives, but those of their neighbors and friends, are placed in jeopardy by these frauds.

We repeat, at the request of a new subscriber, the test for kerosene, as published in the *Journal* some time ago. Take a common quart bowl; fill it one third full of boiling water; now add cold water, a little at a time, until a thermometer placed in it indicates a temperature of 110° F. A tablespoonful of the oil to be tested may be turned into the water, and stirred about with the thermometer. It will float on top, and it may be touched with a lighted match or bit of paper. If it ignites or takes fire, the oil is dangerous, and the seller can be prosecuted under the United States law.

NITROUS OXIDE AS AN ANÆSTHETIC.

Nearly a year since, we took occasion to point out the errors and absurd statements found in the report of a lecture given by Dr. Richardson, of London, before the *Medical Society of London*, upon Nitrous Oxide. These absurdities were passing unchallenged through the medical press of our country, and we were the first to call attention to them. Since that time, a change has taken place, and the Doctor's manifest ignorance and presumption have been freely criticized by the journals. It will be remembered that Dr. Richardson asserted that the gas in question was an *asphyxiating* agent, — not an anæsthetic, — and was a dangerous poison. He represented it as peculiarly fatal to the lower animals when respired, and, in support of these views, pretended to give the results of experiments confirming them. Carefully conducted experiments here show that his statements are entirely false, and that he is most inexcusably ignorant of the nature and properties of nitrous oxide. Dr. McQuillen has recently verified the experiments of others, and presents the results in the *Dental Cosmos* for October. He put rabbits, kittens, and frogs under the influence of the gas repeatedly, and not the slightest injury resulted. He employed forty gallons in his experiments upon three or four of the animals, and kept them narcotized one or two minutes at a time; and yet, they not only recovered, but were lively and well when the influence of the gas had passed off.

Nothing is more apparent than that the views of the great men of England, as well as of our own country, upon medical and chemical matters, must be submitted to careful examination before being fully received and adopted. A great name may be instrumental in disseminating a great error; and all new views affecting important questions, no matter what may be their origin, should pass the ordeal of intelligent criticism and experiment before being admitted as correct.

LIVING GERMS IN THE ATMOSPHERE.

The air we breathe, the water we drink, are full of spores and organic germs, all of which seem to have a purpose to subserve in the economy of things. If any one doubts the statements of scientific men regarding the presence of these germs, they have only to become acquainted with the use of the microscope to convince themselves of their entire truthfulness. Separate from the bark of the common maple-tree a bit of the adhering dry lichen, or *moss*, as it is called, moisten it with water, and place over it a glass slide. The spores or seeds which lie dormant, when the lichen is dry, immediately become vitalized, and rising into the air are caught upon the glass, and with a power of 400 diameters can be seen and studied. This simple experiment will illustrate the origin and nature of what are called spores, and the air is filled with thousands of varieties, arising from as many sources.

Dr. Smith and Mr. Dancer of Manchester, England, have recently been examining the air of that city, and have found it loaded with them. The air was first washed by shaking it in a bottle with distilled water, and in a drop of the water it was reckoned that there were about 250,000 spores. In the quantity of air respired by a man in ten hours, there would be more than thirty-seven and a half millions. All these germs, floating in the air, are ready to spring into activity, whenever the conditions of growth are favorable. The varieties and sources of fungoid growths from which the spores arise are wonderful. A fungus is known which develops only on the corpses of spiders; another, which grows only on the hoofs of horses in a state of decomposition. The *isaria* has as yet been observed only on certain night butterflies; there are other species which invade the larvæ and chrysalides. Hooker has discovered a fungus which attains considerable dimensions (from ten to twelve centimeters), but which is found absolutely only on the neck of a certain caterpillar in tropical countries. It vegetates on the animal, fructifies on it, and the caterpillar buries it with itself in the the ground, whence it springs like a funeral plume. Still more, a singular vegetable is known, the *racodium cellare*, which has never been found except on the casks in wine cellars, and another which lives only on the drops of soot which the workmen let fall on the soil of mines. "Have the seeds of these vegetables remained without use from the origin of the world to the day that they found their proper soil?"

☞ Phosphorus obtained from bird guano is used for tipping lucifer matches in England.

OGDENSBURG WATER SUPPLY.

The citizens of Ogdensburg, N.Y., are moving in the matter of supplying their city with pure water. There are two sources to which attention is particularly turned; one the St. Lawrence River, the other the Oswegatchie River, a short distance from the city. Having been employed by the city to make analysis of these waters, with the view of ascertaining their comparative purity and excellence, we have returned the following results, which we here present in tabular form: —

ANALYSIS OF DIFFERENT WATERS AT OGDENSBURG, MADE BY JAMES R. NICHOLS & CO., CHEMISTS, BOSTON, MASS.

	St. Lawrence R.		Oswegatchie R. Above Dam.		Oswegatchie R. At Eel Weir.	
	Parts in 100,000.	Grs. pr. gall.	Parts in 100,000.	Gr. per gall.	Parts in 100,000.	Gr. per gall.
Total solid impurity..	1.1662	12.6	.8793	9.5	.8747	9.45
Lime as carb. or bicarb.	.5061	5.49	.2887	3.12	.2887	3.12
Lime as sulphate.....	.1092	1.18	.0740	.8	.0694	.75
Magnesia as phos. and carb.	.1157	1.25	.0786	.85	.0786	.85
Organic matter.......	.1878	2.03	.3609	3.9	.3609	3.9
Silicate soda & potassa,	.1943	2.1	.0518	.56	.0518	.56
Iron..................	trace.	....	.0185	.2	.0185	.2
Alumina..............	.....	....	.....	....	.....	....
Chloride sodium......	.0481	.52	.0027	.03	.0027	.03
Ammonia.............	.....	....	.....	....	.....	....
Nitrogen as nitrate and nitrites	.0027	.03	.0037	.04	.0037	.04
Hardness—Clark's test,	8 deg.	....	2½ deg.	....	2½ deg.	....
Hardness after boiling,	6 deg.	....	2 deg.	....	2 deg.	....

It will be seen, that the Oswegatchie River furnishes excellent soft water, well suited to all culinary and domestic purposes. The St. Lawrence water is remarkably clear and sparkling, but it holds a much larger amount of inorganic matter, which being made up of lime salts, renders it too hard for domestic uses. We presume the Oswegatchie will be called upon to quench the thirst of the good people of Ogdensburg.

QUESTIONS AND ANSWERS.

N. T. S., *Syracuse, N.Y.* — "Will you please inform me and many other curious inquirers regaring the probable origin or source of the salt-springs which are found in and about this city? If they come from dissolving salt-beds, is there not danger of undermining the country, and causing it to sink?"

It is obvious that a vast bed of impure chloride of sodium, or rock salt, reposes in the earth beneath your city, and that percolating rains from near and distant hills reach and gradually dissolve it; and, by hydrostatic pressure, it is forced up to the surface, charged with the saline constituents. This salt water is worth more than the rock itself; for if you could chisel or blast off the rock above ground, it would require to be dissolved to remove impurities, and this would be all extra work. Through the silent but mighty workings of nature, the rock is dissolved and brought to the surface, ready for the manipulations of the salt-makers. The second inquiry is of a somewhat startling nature. Is there not danger that, by removal of so much solid matter immense cavities may be formed below, and endanger the stability of the city and suburbs? It is true, a mass of rock salt is removed, every year, equal in size with the bulk of the manufactured article. How great is this? From the reports of the superintendents in past years, we learn that the amount abstracted is increasing each year; and during the present, it will reach as high as 6,000,000 bushels. The statute bushel contains 1.28 cubic feet; the yield, therefore, amounts to nearly 8,000,000 cubic feet. This amount, if piled up, would form a pyramid 290 feet square and 320 feet high. If spread out, it would cover, to the depth of 6 feet, 28 acres of land. The natural wear upon the rock, through the small springs, was comparatively insignificant; but the large number of borings made during the last fifty years have brought up immense quantities of the great saline bed. There can be no question, we think, of the forma-

tion of a huge cavity below, filled with salt water; but it is probable the depth is so great, the superincumbent earth is capable of keeping its position. At any rate, we think real-estate owners in that locality will not be likely to become so disturbed by the prospects of a collapse, as to force their lands upon the market at very ruinous prices.

Mrs. E. G. D., *Newark, N. J.*—The singular occurrences in your house, which you describe, and which created so much alarm, are unquestionably due to electrical excitation. Within a few years past, several house in the city of New York have exhibited electrical phenomena in a very remarkable degree. For months in succession, they have emitted sparks of considerable intensity, accompanied by a loud snap. A stranger, upon entering one of these electrical houses, in attempting to shake hands with the inmates, receives a shock which is quite noticeable and somewhat unpleasant. Ladies, in attempting to kiss each other, are saluted by a spark. A spark is perceived whenever the hand is brought near to the knob of a door, the gilded frame of a mirror, the gas-pipes, or any metallic body, especially when this body communicates freely with the earth. In one house, a child, in taking hold of the knob of a door, received so severe a shock that it ran off in great fright. The lady of the house, in approaching the speaking tube to give orders to the servants, received a very unpleasant shock in the mouth, and was very much annoyed by the electricity, until she learned first to touch the tube with her finger. In passing from one parlor to the other, if she chanced to step upon the brass plate which served as a slide for the folding-doors, she received an unpleasant shock in the foot. When she touched her finger to the chandelier (the room was lighted with gas by a chandelier suspended from the ceiling), there appeared a brilliant spark and a snap. In many houses the phenomena have been so remarkable as to occasion general surprise, and almost alarm. The electricity is probably created by the friction of the shoes of the inmates upon the carpets. If the carpets are all wool, and very heavy and dry, the house close and hot, sparks and slight reports come from persons scuffling over them. In winter, this phenomenon is more likely to occur than at other seasons. There is nothing in the occurrences which should create alarm.

M. C.—"What is the process of curing sheepskins, etc., with the wool on?"

First wash the wool thoroughly with soap and warm water, until all dirt and grease is removed; then either

First, immerse it for three or four weeks in the handling vat of a tanyard; second, sew it up in the shape of a bag, with the wool outside; cram it full of tan bark, pour in as much water as it will hold, and hang it up for two or three weeks; or, third, lay it upon the floor, flesh side up, and plaster it over, half an inch thick, with a composition of one half salt and one half alum, both finely pulverized; double it over and let it stay three weeks. The first two processes will stain the wool somewhat; the last will leave it beautifully white and clean.

B. W. K.—"Can you tell me how to reduce hair to a state suitable for manure?"

Hair resists decay more powerfully than any other organic substance known. It has been found in a perfect state after lying in tombs or graves for centuries. We know of no better way than to incorporate it with your compost heap, and let it undergo fermentation through the winter.

J. S. C.—"Can I use with safety and advantage, as a fertilizer, the marble-dust, whiting, carbonate of soda, etc., which has been employed in obtaining gas for soda fountains, mixed, of course, with oil vitriol?"

First, ascertain which predominates—the carbonate of soda, or the sulphuric acid. If the former, mix it with your compost heap; if the latter, mixed with ground raw bones, it makes a most valuable fertilizer.

D. M.—"1. Would logwood (after boiling) be beneficial, applied to heavy clay land? 2. Would any benefit result from the application of the refuse of chloride of lime to land?"

1. No more than any other sawdust. 2. No more than common marl.

A. K.—"How can I make a good rubber cement that will adhere to cloth, leather, or rubber? I have tried benzine, and find it does not work."

We think your benzine was made from petroleum. You should have taken that made from coal-tar. In case that fails, try chloroform.

L. O. H.—"What power has your petite microscope?"

The one at seventy-five cents, twenty diameters; that at one dollar and twenty-five cents, forty diameters.

S. A. D.—"Please inform me what will remove white paint from broadcloth."

Coal naphtha or benzine.

L. D.—"What will remove stains of iron rust from marble? What will erase ink-spots from marble?"

An aqueous solution of oxalic acid.

F. R. G., *St. Joseph.*—"Can you give me a recipe for indelible ink to be used with a stencil plate?"

Nitrate of silver ground up with India ink.

Yale.—"What is the best study light and study lamp?"

Kerosene in a German student lamp.

Rev. Mr. Milburn, the well-known blind preacher, has hopes of recovering his sight. He is under the care of Prof. Von Græfe, at Berlin.

☞ A gentleman of high scientific attainments, a resident of one of our large cities, in a note ordering two full volumes of the *Journal* to be sent to him, remarks as follows:—

"The practical character of the *Boston Journal of Chemistry* pleases the members of my family; and the only regret expressed is, *that there is not more of it. Silliman's Journal*, the *Journal of the Franklin Institute*, etc., are just glanced at when received; but your *Journal* is *read*."

Medicine and Pharmacy.

STUTTERING OR STAMMERING.

Editor Boston Journal of Chemistry:—

The most common case of stuttering is not, as has been almost universally believed, where the individual has a difficulty in respect to some particular letter or articulation, by the disobedience to the will or power of association, of the parts of the mouth which should form it, but where the spasmodic interruption occurs altogether behind or beyond the mouth; viz., in the glottis, so as to affect all the articulations equally.

To a person ignorant of anatomy, and therefore knowing not what or where the glottis is, it may be sufficient explanation to say, that it is the slit or narrow opening at the top of the windpipe, by which the air passes to and from the lungs, being situated just behind the root of the tongue.

It is that which is felt to close suddenly in hiccup, arresting the ingress of air, and that which closes to prevent the egress of air from the chest of a person lifting a heavy weight or making any straining exertion; it is that also, by the repeated shutting of which, a person divides the sound in pronouncing several times in distinct and rapid succession, any vowel, as *o, o, o, o*. Now, the glottis, during common speech need never be closed, and a stutterer is instantly cured, if, by having his attention properly directed to it, he can keep it open. Had the edges or thin lips of the glottis been visible, like the external lips of the mouth, the nature of stuttering would not so long have remained a mystery, and the effort necessary to the cure would have forced itself upon the attention of the most careless observer; but because hidden,—and professional men had not detected in how far they were concerned, and the patient himself had only a vague feeling of some difficulty, which, after straining, grimace, gesticulation, and sometimes almost general convulsion of the body, gave way,—the uncertainty with respect to the subject has remained. Even many persons who by attention and much labor had overcome the defect in themselves, as Demosthenes did, have not been able to describe to others the nature of their efforts, so as to insure imitation; and I doubt very much whether the quacks who have succeeded in relieving many cases, but in many also have failed, or given only temporary relief, really understood what precise end in the action of the organs their imperfect directions were accomplishing.

Now a stutterer, understanding of anatomy only what is stated above, will comprehend what he is to aim at, by being farther told, that when any sound is continuing, as when he is humming a single note or a tune, the glottis is necessarily open, and therefore, that when he chooses to begin pronouncing or droning any simple sound, as the *e* of the English word berry (to do which at once no stutterer has difficulty), he thereby opens the glottis, and renders the pronunciation of any other sound easy. If then, in speaking or reading, he joins his words together, as if each phrase formed but one long word, or nearly as a person joins them in singing (and this may be done without its being at all noted as a peculiarity of speech, for all persons do it more or less in their ordinary conversation), the voice never stops, the glottis never closes, and there is of course no stutter.

I have given this explanation or lesson, with an example, to a person who before would have required half an hour to read a page, but who immediately afterwards read it almost as smoothly as was possible for any one to do; and who then, on transferring the lesson to the speech, by continued practice and attention, obtained the same facility with respect to it. There are many persons not accounted peculiar in their speech, who, in seeking words to express themselves, often rest long between them on the simple sound of *e* mentioned above, saying, for instance, hesitatingly, "*eIe* . . . . think *e* . . . . you may,"—the sound never ceasing until the end of the phrase, however long the person may require to pronounce it. Now, a stutterer, who, to open his glottis at the beginning of a phrase, or to open it in the middle after any interruption, uses such a sound, would not even at first be more remarkable than a drawling speaker, and he would only require to drawl for a little while, until practice facilitated his command of the other sounds. Although producing the simple sound which we call the *e* of berry, or of the French words *de* or *que*, is a means of opening the glottis, which by stutterers is found very generally to answer, there are many cases in which other means are more suitable, as the intelligent preceptor soon discovers.

Were it possible to divide the nerves of the muscles which close the glottis, without at the same time destroying the faculty of producing voice, such an operation would be the most immediate and certain cure of stuttering; and the loss of the faculty of closing the glottis would be of no moment.

The view given above of the nature of stuttering and its cure, explains the following facts, which to many persons have hitherto appeared extraordinary. Stutterers often can sing well, and without the least interruption,—for the tune being continued, the glottis does not close. Many stutterers also can read poetry well, or any declamatory composition, in which the uninterrupted tone is almost as remarkable as in singing.

The cause of stuttering being so simple as above described, one rule given and explained may, in certain cases, instantly cure the defect, however aggravated, as has been observed in not a few instances. And this explains also why an ignorant pretender may occasionally succeed in curing, by giving a rule of which he knows not the reason, and which he cannot modify to the peculiarities of other cases. The same view of the subject explains why the speech of a stutterer has been correctly compared to the escape of liquid from a bottle with a long narrow neck, coming "either as a hurried gush or not at all;" for when the glottis is once opened, and the stutterer feels that he has the power of utterance, he is glad to hurry out as many words as he can before the interruption again occurs.

Should my future experience enable me to simplify, or render more complete, the views of the nature and cure of stuttering which I have given above, so as to facilitate the cure in every variety of case, I will not fail to publish my remarks. D. J. Lyster, M.D.

CARBOLIC ACID IN TONSILLITIS.

BETHEL, Ky., Oct. 31, 1868.

DR. NICHOLS:—I read with pleasure, in the last number of the *Journal*, your remarks upon carbolic acid and its therapeutic applications. Judging from its chemical nature, I concluded, some time ago, to test its value in angina, tonsillitis, and other affections of the mouth and throat. I found it very beneficial. I was recently applied to by a gentleman suffering from severe mercurial stomatitis; and as a mouth-wash, I never found its superior. The unpleasant fetor was at once destroyed, and the entire ulcerative process checked. With a desire to benefit all, through the pages of the *Journal*, I concluded to forward this note.

With sentiments of high regard, I remain,

Yours truly, J. L. RICHARDSON, M.D.

QUININE MIXTURE.

Editor Journal of Chemistry:—

I wish to give to your readers the following formula, which I have used very satisfactorily for the last two or three years, viz.:—

℞	Sulphate quinine	grs. xx
	Tannic acid	grs. x.
	Comp. spts. lavender	fl. ℥ i.
	Aqua	℥ i.
	White sugar	q.s.

Mix.

By this combination the bitter taste of quinine is neutralized by the acid, while its medicinal character is not in the least impaired. Even children make no objection to taking it, so far as taste is concerned. The dose can be regulated by the amount of quinine the physician may wish to give in a given time. In intermittents and remittents, I generally give to an adult the above amount between each paroxysm, divided into three doses and given every two or three hours.

L. D. MCKINLEY, M.D.

E. MELROSE, Monroe Co., Io.
Nov. 3, 1868.

CARBOLIC ACID IN CONJUNCTIVITIS AND DIARRHŒA.

Dr. Ten Brook, of Paris, Illinois, has been using carbolic acid in obstinate cases of conjunctivitis, both acute and chronic. He writes to the *Medical and Surgical Reporter*, that its action was prompt and comparatively painless.

Dr. Fergus, in the *British Medical Journal*, describes a case in which he gave carbolic acid for excessive diarrhœa. The patient was a child not two years old, suffering from an attack of fever of the enteric type. The form used was the crystallized acid dissolved in a little sugar and water, commencing with doses of a half grain, afterward increased to two thirds grain every three hours. The diarrhœa was checked in less than two days, and the patient recovered. Two older children were attacked, but a prompt treatment with the acid cured them at once.

SUN-BATHS

Cost nothing, and are the most refreshing, life-giving baths that one can take, whether sick or well. Every housekeeper knows the necessity of giving her woolens the benefit of the sun, from time to time, and especially after a long rainy season or a long absence of the sun. Many will think of the injury their clothes are liable to from dampness, who will never reflect, that an occasional exposure of their own bodies to the sunlight is equally necessary to their own health.

The sun-baths cost nothing, and that is a misfortune, for people are still deluded with the idea that those things only can be good or useful which cost money, and they will cheerfully pay away their dollars for Turkish and Russian Baths, when they could get any number of sun-baths, which would be far more beneficial to them, for nothing.

Let it not be forgotten, that three of God's most beneficent gifts to man—three things the most necessary to good health—sunlight, fresh air and water are *free* to all; you can have them in abundance, without money and without price, if you will. If you would enjoy good health, then see to it that you are supplied with pure air to breathe all the time; that you bathe for an hour or so in the sun-light; and that you quench your thirst with no other fluid than water.

In regard to sun-baths, let any invalid … and who has been housed for some time, ta… sional walk in the sun, if it should be only on the piazza … and observe the effect. In our opinion, he will find it the most healthful bath he has ever taken.

Sleeping-rooms should be selected in such parts of the house as have the most benefit from the rays of the sun; the bed and bedclothes should be thoroughly aired and kept in the sun as long as possible every day. Many of the sleeping-rooms in our hotels are so situated as never to feel the influence of the sun's rays, and those who occupy such rooms for any length of time, are simply committing suicide. We have in mind, now, a large hotel in the vicinity of New York city, where not less than two hundred persons are usually located for the winter, in which a large proportion of the bedrooms are in the centre of the building, into which the sunlight never penetrates. As a corollary, the doctors' gigs are seen standing before the house at all hours of the day.

The Italians have a proverb, which says, "*Dove non entrar il sole deve andar il medico;*"* and with them, the first point to be considered in the selection of a house, is: *What is its exposure to the sun?* and they are careful to locate their sleeping-rooms on the side of the house where there will be the most sun.

Again: too many houses in most of our cities, and very many in country villages, are completely buried from the sun by shade-trees. Elegant establishments, these houses, whose occupants can command every luxury within the reach of wealth; saloons into which rank, beauty and fashion are welcomed, but from which the sunlight of heaven is totally excluded by shade-trees!

At the risk of being denounced as an iconoclast, we would lay the axe to the root of at least two thirds of the shade-trees which surround our houses and line our streets.—*Jour. of Health.*

REMOVING AMALGAM.—Dr. J. Payne writes to the *Am. Jour. of Dental Science*, that, in removing old amalgam fillings, he finds it a saving of much time and labor to first soften the amalgam by the addition of a little fresh mercury. A portion of quicksilver is taken up on the point of a piece of silver wire, and brought in contact with the plug. Having a stronger affinity for the amalgam than for silver, it immediately leaves the wire, and incorporates itself with the plug, which, in a few minutes, it reduces to as soft a state as when first made. The instrument should be well scoured after using, to prevent the silver from oxidizing.

RELATIVE MORTALITY FROM SMALL-POX.—Thirty years before vaccination was introduced into England, the mortality from small-pox was 3,000 to the million of population; now it is only 171 to the million. The mortality in the small-pox hospital is ascertained to be, in non-vaccinated cases, 37 per cent; while that of the vaccinated was only 6½ per cent. It seems, that in the great majority of instances, to have been vaccinated renders one proof against the contagion, as though one had passed through the original disease itself.

POISONING BY ABSORPTION OF CARBOLIC ACID.—E. S. Machin, Esq. (*British Med. Jour.*) refers to three cases of itch where the parts were dressed with carbolic acid and symptoms of poisoning ensued, consisting of smarting pain at the point of application, headache, and coma. Two of the patients actually died, and the third was only rallied with considerable difficulty. The acid used was that known as Calvert's, and about six ounces were employed upon the three cases.—*Med. and Surg. Journal.*

THE PROTOXIDE OF AZOTE is being employed as an anæsthetic by Dr. Seymour in the extraction of teeth, producing complete insensibility in two minutes. It is said to be perfectly innocuous, and to be respired without difficulty or repulsion.—*La France Medicale.*

IN INDURATED HEMORRHOIDS, M. Hillairet employs suppositories containing one tenth part of iodoform. In a few days the hemorrhoids soften and wtiher.

* Where the sun does not enter the doctor must.

…CURE FOR RHEUMATISM.

…, L. C. P. L., writes to the *Medical Press* …, that he has tested with most gratifying results … efficacy of valerian, in the form of a bath, in arresting the most violent attacks of acute rheumatism.

The bath is made by gently boiling one pound of valerian root for a quarter of an hour in one gallon of water, straining, and adding the strained liquid to about twenty gallons of water in an ordinary bath-tub. The temperature should be about ninety-eight degrees, and the time of immersion from twenty minutes to half an hour. After coming out of the bath, the patient should be rubbed till completely dry. If the inflammation continue in any of the joints, apply poultices made of linseed meal, wet up with a strong decoction of valerian root.

TURPENTINE AS AN ANTIDOTE TO PHOSPHORUS.—The *Archives Gén de Médecine* calls attention to the custom of the workmen in a match factory at Stafford, who apply phosphorus to the matches, of carrying on their breast a tin cup, containing essence of turpentine. This precaution is said to be sufficient to prevent any ill effects from the action of the phosphorus. It was previously known that the vapor of turpentine prevents the ignition and even the phosphorescence of phosphorus, but the practical application of this knowledge is not so generally adopted as it should be.—*Med. and Surg. Journal.*

STARVATION OF INFANTS.

It is very certain that infants other than those designedly starved to death, suffer from an insufficient supply of nutriment, and often die in consequence of withholding a proper amount of food, by kind but ignorant mothers and nurses. Modern mothers, from some reason, have but imperfect development of those functions upon which their offspring are expected to depend for nourishment during the tender period of infancy. Nearly or quite one half the children born, need other support than that obtained at the maternal fountain, and physicians and nurses cannot be too careful or vigilant in regard to this matter. Cow's milk, as furnished through ordinary sources of supply, is not pure and reliable, and if it were, cream properly diluted is usually better; cream mixed with thin arrowroot, is most excellent food for infants, and they thrive upon it wonderfully.

Our object in introducing this subject is, to call attention to some sensible views found in an article contributed by Dr. Hiram Corson, of Montgomery County, Pa., to the Transactions of the State Medical Society of Pennsylvania. Dr. Corson is of the opinion that a majority of infants fed by hand are underfed, and their milk given far too dilute.

"Thirty-two years ago it became necessary to rear his own child by hand, and then he discovered how ignorant he had been in relation to the *quantity of food* necessary for an infant, and was also able to observe the effect of an insufficient amount of food. Subsequent observations, continued through those many years, have convinced him that there is not more than one woman in five or ten who knows what amount of milk a child should have. Nor is there one physician in very many who can tell the mother or nurse what quantity it will need in twenty four hours. He has repeatedly questioned mothers, nurses, and physicians, and it has been rarely that they ever approximated the truth; guessing, as they did, from a teacupful or less, up to a half-pint or more, of one half to two thirds water, and one half to one third milk.

"Now, scarcely any child of one month will be satisfied with one pint of pure milk daily; many will take a quart; the average is between the two. It needs from twenty-four to thirty-two ounces of milk daily, and will starve on three half-pints of fluid, two thirds of which are water; for then it will only get eight ounces of milk per day. Such an underfed child will be hungry, peevish, fretful; will moan, start in its sleep; look pale, have an acid stomach, be colicky, be considered sick, be dosed with medicine, for the food is still insufficient in quantity and defective in quality, and will finally die. Thousands upon thousands of infants suffer thus daily, both in the

country as well as in the cities. It is not u[...] see children who have thus been dosed an[...] weeks, have their diet still farther reduced by [...] physician, who fears that the babe's stomach is too weak to bear much food. Such a babe becomes thin, pale, sad looking, moans much, and its mother becomes wearied out with it. If the weather is warm diarrhœa may set in; in cold weather it may be very costive. Sometimes it looks blue, as in cyanotis, and its face is always shrivelled, and its arms and legs thin; next it will break out in sores over its arms, face and legs, and its blood is supposed to be impure. But it is merely starving slowly; and its blood is only thin and scanty.

"In other cases it may be supposed to have disease of the heart. But its little, pinched up old face, with the fat all gone, and the attenuated muscles, standing out like strings when it cries or whines, will satisfy the observing physician that the child is starving. It gets only one or two teacupfuls of half milk and half water a day, when it ought to have more than a pint of pure milk, and over a quart a day, if it could take it, although it is only two months old.

"Cases of bowel complaint caused by water and milk should not be treated with medicine; merely give the babe as much good milk as it can take, and it will soon be well. But there is great difficulty here, for the mothers are generally impressed with the idea that cow's milk is very strong, even when they are giving this miserable sloppy water and milk mixture. Suppose that, instead of using half or a whole pint of this miserable stuff, the mother should give her babe even a whole quart daily; even then her child will be most wretchedly starved. It continues to be weak and pale, and be sick and puny; restless, both by day and night, wearing its mother out with its misery. If its condition is attributed to disease, and medicine is given, its fate will be sealed. Vomiting is apt to set in, and cold water is withheld, from fear of weakening the stomach; but little children not only need plenty of good food, but also a little cold water occasionally.

"These cases are still more difficult to understand and treat if the mother nurses her child in part, and feeds it also. It will generally be found that the babe gets little or nothing from the maternal fount, and then is kept on very low diet, from fear of surfeiting it. It will become sickly, puny, break out in sores, and become scorbutic.

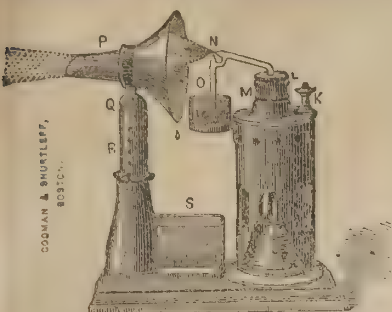
"The major part of the colic, crying, and restlessness of new born babes, for the first few days or weeks of their lives, comes from starvation. Cream and water will cure them far quicker than catnip, or aniseed, or chamomilla tea, or carminatives, or anodynes of any kind.

"Corson feels quite certain that it is almost as easy to raise children by hand, if they have an abundant supply of good, undiluted cow's milk, as it is by the breast. But the bottle should always be used instead of the spoon; and as much milk may be given as the child can take, and as often as it wants it, provided it is always made as warm as breast milk. To accomplish this it is only necessary to put two tablespoonfuls of boiling water to a pint of cool milk, and sweeten it moderately. A healthy child, one month old, will take nearly two pints in twenty-four hours; and some children, between one and two months old, will take more than a quart.

"It is not only flabby and flaccid breasts which give but little milk, but it frequently happens that stout women, with very large, fat breasts, have no milk at all. It is easy enough to notice the error when the little hungry creature is seen tugging at flaccid, milkless breasts, but it is far more difficult to detect the sham when it is seen struggling with a mountain of fat and flesh.

"It is not merely the children of the poor who are thus starved. Who has not seen the poor little emaciated child of the rich, dragged about in its superb little wagon, or lying on the nurse's lap as the large carriage rolled along, to give it an airing, by direction of the physician, under whose very precise orders it had been fed only every four hours, on two thirds water and one third milk. Day after day, and week after week, he has visited and prescribed, not for the starvation, but for debility, colics, sourness of stomach, irregular or disordered bowels. Under the impression that the child's stomach was weak, he has still further reduced its nourishment, and given it lime, or mint-water, chalk, bismuth, anodyne, etc. *This is starvation in the midst of plenty — starvation by prescription.*

Local Anæsthesia and Atomization of Liquids.

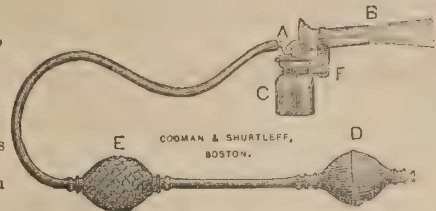


Will be sent by mail,

postpaid, on application,

A PAMPHLET

Containing two articles by distinguished foreign authority on



INHALATION OF ATOMIZED LIQUIDS, with formulæ of those successfully employed.

An article by Dr. J. L. W. THUDICHUM, M.R.C.P., on A NEW MODE OF TREATING DISEASES OF THE NASAL CAVITY, with his formulæ.

An illustrated description of the *best apparatus* for the above purposes, and for producing Local Anæsthesia by Atomization, with Ether, by the method of Dr. RICHARDSON of London, or with Rhigolene, as described by Dr. HENRY J. BIGELOW in the *Boston Medical and Surgical Journal* of April 19, 1866. The following is an extract from a note from Dr. Bigelow:

"I have thus far found nothing better for freezing with Rhigolene than the tubes made by you after the pattern I gave you, and which I still use with your other apparatus."

Dr. J. Mason Warren says:

"Your apparatus for Atomization of Liquids seems to have been carefully made, and I think it an efficient one where required for treatment of diseases of the Throat and Lungs. The apparatus for Local Anæsthesia which you made for me answers the purpose perfectly."

ALSO FOR SALE,

Rhigolene, for Local Anæsthesia, per bottle	$1 00	Hypodermic Syringes	$4 00 to 16 00
Cammann's Stethoscopes, Articulated	8 00	Miller's Intra-Uterine Scarificator	7 00
" " Disarticulating	8 50	" " " " (in case) postpaid	8 50
Laryngoscopes, complete	17 00 to 28 00	Æsthiometers	3 50 to 5 00
Simple Throat Mirrors	1 50	Lente's Intra-Uterine Caustic Instruments	1 50 to 4 00
Ophthalmoscopes, Liebreich's	7 50	French Rubber Urinals, with valves, male, for night or day,	6 00
Holt's Dilator	18 00	" " " " " " day only	4 00
Barnes' "	10 00	" " " " " female, for "	3 00
Heurtloupe's Leech	14 00	Vaccinators, Automatic, in case, postpaid	4 00

Trusses, Spinal and Abdominal Supporters, Shoulder Braces, Suspensory Bandages, Elastic Hose, Medicine Trunks and Pocket Medicine Cases, Otoscopes, Endoscopes, Inhalers adapted to Dr. Cutter's new method with Ether, Fever Thermometers, Respirators, Syringes, Crutches, Universal Syringes, Galvanic Batteries and Apparatus.

Skeletons, Skulls, Manikins, Anatomical and Pathological Models and Charts on hand, or imported to order. Prices on application.

All Instruments, Implements, and Materials used by Dentists, always on hand.

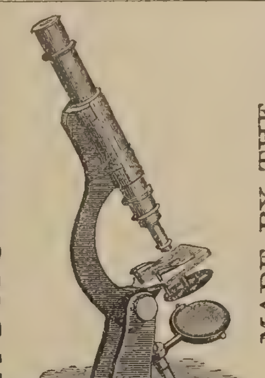
Apparatus for Club Feet, Weak Ankles, Bow Legs, Spinal Curvature, and other deformities, made to order.

Instruments sharpened, polished, and repaired.

CODMAN & SHURTLEFF, 13 & 15 TREMONT STREET, BOSTON,

Makers and Importers of Surgical and Dental Instruments.

STUDENT'S MICROSCOPE.



MADE BY THE BOSTON OPTICAL WORKS.

This instrument is of the size and pattern most highly approved by experts,—15 inches high, weight 6 lbs. The base, uprights, and curved arm of iron, handsomely japanned. It has one Eye-Piece, two second-class objectives of about 1 inch, and ¼ in. power, giving about 90 and 350 diameters; plain stage with clips for holding the object slides, revolving diaphragm, concave mirror, with motion in all directions; for illumination of opaque objects, the mirror is removed to a separate stand; coarse adjustment for focus is effected by sliding the tube; fine adjustment, by a new construction which is efficient with the highest powers in general use. The whole in an *upright* Black-Walnut Cabinet. The stand is made with all the care bestowed upon their first-class instruments, and proves efficient for the use of Amateurs, Students, and the ordinary work of the medical profession. Price $65.

ADDITIONS.—Extra Eye-Pieces will be supplied at $4 each. A superior Camera Lucida, at $5. A hand-movement Stage, at $10. Sub-Stage, for accessory apparatus, at $12. Packing boxes for transportation by express, $1.

THE BOSTON OPTICAL WORKS

ALSO MAKE TO ORDER,

Prof. J. L. SMITH'S INVERTED MICROSCOPE for Chemists, and TOLLES'S First-Class TRUNNION MICROSCOPE.

Objectives for Microscopes, either dry or wet, of unsurpassed excellence. Tolles's Improved Telescopes.

All letters and orders should be addressed to

CHARLES STODDER,

75 KILBY STREET, BOSTON.

WINE OF WILD CHERRY BARK.

(Prunus Virginiana, or Cerasus Serotina.)

"The bark of the wild cherry is among the most valuable of American remedies. Uniting with a tonic power the property of calming irritation and diminishing nervous excitability, it is admirably adapted to the treatment of diseases in which debility of the stomach, or of the system, is united with general or local irritation."

For the information of physicians, we give a general statement of our method of producing Wine of Wild Cherry Bark. The best bark is selected, reduced, and exhausted of all its properties, without the aid of heat. The result is a liquid in which resides in a latent condition the sedative principle, and this is developed only by bringing the amygdalin of the bark, which hides this principle, into contact with emulsin: this reaction liberates hydrocyanic acid, which thenceforth constitutes one of the most active and valuable principles of our preparation. Sound sherry wine is then added in such proportion as to act as an adjuvant to the combined virtues of the drug.

The remarkable sedative properties of this bark are in this preparation fully developed, and constitute, with the tonic bitter, a very efficacious and palatable remedy. Physicians who prescribe "Wine of Wild Cherry Bark" should be particular to obtain that preparation which combines all the virtues of the drug. Prepared by

H. & J. BREWER,

263 MAIN STREET, SPRINGFIELD, MASS.

Saturated Solution of Carbolic Acid.

This solution is very convenient for use, as it is prepared ready at hand, and may be used wherever Carbolic Acid is required.

Directions.

FOR DISINFECTING PURPOSES.—For disinfecting night-vessels and all fecal matters, urine, pigsties, stables, cesspools, etc., dilute with four parts of water and sprinkle over the offensive substances, or around the premises.

FOR PRESERVING CORPSES.—Use the solution full strength; apply with a sponge, and sprinkle over the clothes.

FOR DESTROYING CONTAGION IN SICK-ROOMS.—Dilute with four parts of water, and sprinkle around the room. Carbolic Acid is the only safe disinfectant that destroys contagious emanations.

FOR CLEANSING ULCERS AND BAD SORES.—Dilute with three parts of water, and apply with soft sponge. It causes smarting, but it soon passes away.

FOR THE ITCH.—Dilute with four parts of water, and apply with a sponge over the whole body once or twice. Sprinkle it over the clothing to destroy the spores.

FOR KILLING INSECTS ON PLANTS.—One part of solution to six of water. Sprinkle over the plants so that it will come in contact with the insects; in five or ten minutes syringe well with pure water.

J. R. NICHOLS & CO., Manufacturing Chemists,

150 CONGRESS STREET, BOSTON.

FOR SALE—An extensive medical practice upon one of the Sandwich Islands, with house, lot, furniture, stock of medicines, etc. To a young man capable of enduring a good deal of horseback riding, and desirous of stepping at once into a large and varied practice, this offers unusual inducements. For particulars, please address GEO. S. CHASE,

Office Journal of Chemistry, Boston, Mass.

Infusum Opii Deodoratum.

"The revised edition of the U. S. Pharmacopœia fortunately contains a formula for a preparation of opium which fully meets all the desirable ends contemplated in this communication. It is called *Tinctura Opii Deodorata*; and in its preparation, an aqueous solution of opium is first obtained, which holds all the normal soporific constituents,—morphine, codeine, narceine, without the resin, lignin, earthy matter, etc.;—and then, with the use of ether and alcohol, most of the narcotine, papaverine, thebaine, gum, bassoren, and albumen are removed.

"It is to be regretted that the name *Infusum Opii Deodoratum* was not adopted instead of that given it, inasmuch as it is effectively a watery solution, and not a *tincture*.

"In order to have this most excellent preparation fulfil perfectly all those desirable ends of which it is capable, the opium used should be accurately assayed, in order that perfect uniformity be maintained in the preparation. Opium, as found in the market, differs so largely in the amount of morphine salts contained, that no preparation can be reliable which is not made from that of ascertained strength. The great danger arising from the use of ether, and the want of suitable apparatus and experience, causes this officinal, in its manufacture, to rest under the disadvantage of not being adapted to the shop of the ordinary apothecary. It should only be made by those having competent knowledge and suitable laboratory appliances to render it accurate and reliable.

"The ordinary sedative dose of this is twenty-five drops, equal to about one sixth of a grain of the opium alkaloids.

"If much pain or irritation is to be combated, ten, fifteen, or twenty-five drops more may be required. A pleasant tranquillity and calmness is usually produced by the minimum dose; but in some cases, to complete the effect and produce quiet sleep, a repetition of the dose is required.

"The advantages of this preparation are, that the cerebral disturbance, constipation, and other unpleasant consequences resulting from the use of opium in the usual forms, are entirely, or in a great measure, avoided.

"This form of the drug may be resorted to to produce soporific and anodyne effects, when the others could not be ministered with safety; and therefore it is calculated to meet a want long felt by every physician in active practice."—*Extract from Dr. Nichols's paper on Opium and its Alkaloids.*

This most excellent preparation of Opium is prepared by the subscribers, with great care, from opium which is proved of uniform strength by careful assay. It is placed in packages holding one ounce and one pound, each package bearing our name and label. Orders promptly executed.

JAS. R. NICHOLS & CO., Manufacturing Chemists,

150 CONGRESS STREET, BOSTON.

Liquid Permanganate of Potash.

For cleaning and making sweet, musty or bad-smelling Casks or Vats, used for holding Cider, Beer, etc.

It is well known that Cider, Beer, Wine, Vinegar, etc., no matter how good, are spoiled by being put into foul or musty casks.

Permanganate of Potash is one of the most powerful purifying and deodorizing agents known, immediately destroying most organic substances brought into contact with it; and it possesses the advantage over all other disinfectants of being perfectly harmless and inodorous, at present being largely used for the purification of water.

These qualities have led us to apply it for the purpose mentioned. The great success which has attended its use up to the present, gives us confidence in recommending it to the trade generally, knowing that in practice it is perfectly suitable for the purpose; and casks treated with it do not affect cider, beer, or other beverages in any way. To brewers and cider-makers who know the difficulty of *curing* musty casks, the Permanganate of Potash will prove of great advantage. Its action is so rapid that the most foul cask is rendered perfectly sweet in a few minutes.

It can also be used for the *prevention* of must, and the system of treating every cask with a small quantity of Permanganate before being filled is at present employed with great advantage.

☞ The contents of each bottle is sufficient to cleanse four casks of thirty-six gallons each.

DIRECTIONS FOR USE.—Put into a barrel of thirty-six gallons, previously well cleaned, one quarter the contents of the bottle, mixed with about one gallon of boiling water; turn it round immediately, so as to bring the liquid into contact with every part of the sides and ends, then fill up with cold water and let stand for a short time; when the liquid loses the last trace of a pink color, and becomes brown, the work is finished.

Price per bottle, 75 cents.

PREPARED BY

JAMES R. NICHOLS & CO., CHEMISTS,

150 CONGRESS STREET, BOSTON.

BOSTON DRUG MILLS, No. 90 North Street, Boston. Drugs, Dye-Stuffs, Chemicals, Crude Substances, etc., cleaned, bruised, crushed, ground, powdered, bolted, or dusted, by careful and experienced millers.

Our wagons will call for goods in any part of the city, on receipt of order. J. C. PIERCE, Agent.

E. C. PIERCE, Secretary.

FISH GUANO for sale by J. M. LINCOLN & SON, 140 Commercial Street, Boston.

TO PHYSICIANS.—Prof. HORATIO R. STORER will deliver his FOURTH PRIVATE COURSE of TWELVE LECTURES on the TREATMENT OF THE SURGICAL DISEASES OF WOMEN, during the first fortnight of December, with illustrative operative instruction at the Franciscan Hospital for Women, under his charge.

Fee $50, and Diploma required to be shown. Certificates of attendance upon the previous courses have now been issued to twenty-nine gentlemen in different parts of the country.

Hotel Pelham, Boston, September, 1868.

FOR SALE CHEAP—A PHYSICIAN'S PRACTICE, with house, lot, and fixtures, within an hour's ride by railroad from Buffalo. Reasons—wish to go West. For particulars, address

E. W. MARSH, M.D., Darien, N.Y.

FOR SALE—ONE HALF INTEREST IN A DRUG-STORE.—Miscellaneous Stock, Books, Stationery, News Depot, Paints, Groceries, etc. Splendid location; fifteen years established; six present proprietor. Cash required, about three thousand dollars ($3000). *Reason*—Too much business and too little capital. None but a *live* man need apply. Reference given and required.

Address, M. P. ROBERTS,

Oct. 1, 1868. Sheboygan Falls, Sheboygan Co., Wis.

Long Island College Hospital.

BROOKLYN, N. Y.

The Session for 1869 will commence March 7, and continue until July.

FACULTY.

FRANK H. HAMILTON, M.D., Professor of Surgery.
SAMUEL G. ARMOR, M.D., Professor of the Principles and Practice of Medicine and Pathology.
CORYDON L. FORD, M.D., Professor of Anatomy.
E. S. DUNSTER, M.D., Professor of Obstetrics and Diseases of Women and Children.
GEORGE W. PLYMPTON, Professor of Chemistry and Toxicology.
BENJAMIN HOWARD, M.D., Professor of Operative and Clinical Surgery.
WILLIAM T. LUSK, M.D., Physiology and Microscopic Anatomy.
ANDREW H. SMITH, M.D., Materia Medica and Therapeutics.
ALEXANDER J. C. SKEENE, M.D., Instructor in Clinical Obstetrics and Diseases of Women and Children.
GEORGE K. SMITH, M.D., Demonstrator of Anatomy.

An ORIGINAL FEATURE in the method of instruction in this College, is the union of demonstrative with didactic teaching. *Daily Recitations* will be connected with the course, and all the lectures will be given within the Hospital Buildings, corner of Henry and Pacific Sts.

FEES.

Tickets to all the Lectures	$140 00
Matriculation Fee	5 00
Demonstrator's Ticket, including material for dissection	10 00
Graduation Fee	25 00

Hospital free.

Offer to the Drug Trade a full assortment of

DRUGS, ESSENTIAL OILS, &c.

Pure and prime, at lowest market prices; also

PATENT MEDICINES,

At lowest rates; DRUGGISTS' SUNDRIES and PERFUMERIES; and a large stock of SPONGES, of all grades. Special attention given to the production of

PURE POWDERED DRUGS AND SPICES.

All goods powdered by E. R. SQUIBBS.

Agents for Sturgis's Electric Compound.

THE MASON & HAMLIN

CABINET,

METROPOLITAN,

& PORTABLE

ORGANS.

Observe Reduced Prices.

$50 to $1000 each.

THE MASON & HAMLIN ORGAN COMPANY, winners of the Paris Exposition Medal and seventy-five other First Prizes, for the best work, whose organs are the ACKNOWLEDGED STANDARD OF EXCELLENCE in this department, recommended as the best by MORE THAN THREE HUNDRED of the MOST PROMINENT musicians in this country and Europe (see this testimony in full in circulars), offer the greatest variety of styles of organs for all uses, including a first-class FOUR-OCTAVE ORGAN for $50, a DOUBLE REED FIVE-OCTAVE ORGAN, FIVE stops, with Tremulant and modern improvements, for $125; a MASON & HAMLIN CABINET ORGAN, FIVE-OCTAVE, DOUBLE REED, with new and exquisite VOX HUMANA and FIVE STOPS; *the finest instrument of its size made*; for $170. Elegant styles for Drawing-Rooms, in richest cases, many modern styles of finish.

The Mason & Hamlin Organs owe their superiority and unequalled reputation not to excellence of workmanship and material alone, but also to the exclusive use of many important patented improvements.

TWO NEW INVENTIONS

Are introduced this season.

THE MASON & HAMLIN IMPROVED VOX HUMANA produces the most exquisite effects, including imitations, not only of human voice, but also of Violin, Clarionet, French Horn, etc.

THE MASON & HAMLIN DESK ORGAN is a school-teacher's desk and school organ, both complete in every respect, but occupying no more room than the desk alone, and sold for $100.

REDUCTION IN PRICES.

Having now occasion to turn out a much larger number of instruments of this class than any other maker in the world, and making, as they do, all parts of the instruments themselves, they are enabled to employ machinery in parts usually made by hand-labor, thus securing not only the MOST UNIFORM AND BEST WORK, but also the GREATEST ECONOMY OF COST. They are therefore now furnishing their well-known organs, at *prices which will compare favorably with those demanded for greatly inferior work.*

Circulars, with many illustrations, and full descriptions of new inventions and recent improvements, and fifty different styles of organs, sent post free to any applicant. Address,

MASON & HAMLIN ORGAN COMPANY,

154 TREMONT STREET, BOSTON;

OR, 596 BROADWAY, NEW YORK.

PURCHASING AGENCY.

The undersigned having opened an Office, in connection with this paper, offers his services as AGENT for the purchase of

Medical and Scientific Books,

Surgical Instruments, Chemical Apparatus, Vaccine Virus, etc.

Orders accompanied by the money, promptly attended to.

MANUFACTURERS OF

LOZENGES AND PIPE.

C. & Co. manufacture expressly for the Druggist and Apothecary trade. Dealers will find their goods the

BEST, CHEAPEST, AND MOST RELIABLE,

As they possess superior facilities for manufacturing, use no adulteration in any of their goods, and have received the confidence of the trade for the past twenty years in this country; also have had some years' experience in the business in England. Particular attention is directed to their

CREAMELLOW LOZENGES,

Which do not become hard or brittle. These goods are having an extensive sale, and meet the commendation of all. *Send for Circular and Prices.*

TO THE MEDICAL PROFESSION.

Hernia and General Deformities

The celebrated RADICAL CURE TRUSS, of Dr. Marsh, for the cure of Oblique Hernia, together with Relief Trusses suited to any form of Hernia, and Instruments for Spinal Curvature, Hip Disease, and all Deformities, can now be had, with surgical treatment, at the only office east of New York,

33 TREMONT STREET, BOSTON, MASS.

(OPP. FRONT DOOR OF MUSEUM),

The Radical Cure Truss and above appliances, indorsed for many years as leading inventions by the late Prof. Valentine Mott and the principal surgeons of the United States, are now presented to the New-England public, saving time and distance to New York.

Marsh's Elastic and Spring Supporter, Elastic Belts, Stockings, etc., applied by late attendant. Orders from physicians and the trade solicited. Send for circulars.

Dr. W. R. BONSALL,
Late of Marsh's Institute for Deformities, N. Y.

Iodide of Lime.

One ounce of this salt may be dissolved in two pints of boiling water. It forms a colorless solution, holding all the iodine. A precipitate of the superfluous lime takes place, in the form of a carbonate, which may be removed by filtration. A fluid ounce contains two grains of iodine, the dose of which is one or two teaspoonfuls two or three times a day. It has proved to be superior to iodide of potassium as an alterative, never disagrees with the patient, and is almost tasteless. A drop or two of acid added to the solution decomposes it, and sets free the iodine.

Familiar Science.

IMPURITIES OF WATER.

Chemically speaking, pure water does not exist. Rain-water always contains ammonia or nitrous compounds. Ordinary distilled water also always contains traces of ammonia or other organic substances. We can, however, by observing certain precautions, obtain distilled water very nearly chemically pure; but then it becomes almost impossible to keep it so, for water may be said to resemble, to a certain extent, the alchemists' Universal Solvent, inasmuch as it dissolves greater or less quantities of almost all substances. The expressions *soluble* and *insoluble* in water are therefore usually only relative. We have substances of all degrees of solubility, from those dissolving in any proportion, to those requiring fifty or a hundred thousand parts of water for solution. To this cause is due the difference in natural waters. These always hold various mineral salts in solution, derived from the soil or rocky strata through which they have passed. When these salts are present only in moderate quantity, they do not injure the water for ordinary purposes; or, in other words, they are not practically impurities. In large quantities, they make mineral or saline waters. We have also the division of well, spring, and lake waters into hard and soft, according to the amount of lime they contain. But, besides the mineral substances, that, as they are always present, may be termed essential, our waters are liable to be contaminated with various accidental impurities. These are of a more important character, since they are not always easily recognizable, and are often injurious to health. From a variety of causes, these impurities have not attracted much attention; but, at the present time, their importance is acknowledged, and the determination of their nature and effects has become one of the most difficult of chemical problems. We propose, in the present article, to touch upon some of the salient points of this subject, without entering into its minute details. It is a matter which especially affects the dwellers in cities. A man living under his own vine and fig-tree may also have his own well or spring; but the inhabitants of a large city depend upon a common source for their supply of water, and when this becomes impure, all must experience its evil effects. It is soluble organic impurities that are most to be dreaded, and especially the presence of some forms of decaying organic matter in drinking water. We will take up this point again farther on.

Water-supply is usually obtained from lakes or rivers. Lake water of course is to be preferred, when obtainable. Especially is it the best when the lake is so situated that it is fed only by springs or brooks, and does not receive the drainage of towns or factories. In this way, it is certain that, under ordinary circumstances, it will not be contaminated by organic matter. Occasionally, fungoid or other vegetable growths may be found in it; but such causes will produce only transient effects. River water always holds in solution more organic matter than lake water. Often it holds in suspension, mud, largely organic; and, beyond all, it is likely to receive the drainage of the towns, villages, and farms along its banks. Muddy or turbid water can be easily freed from suspended matter by settling or filtration; but, of course, the soluble constituents are not affected by either operation. We have said above, that it is soluble organic impurity that is most to be dreaded. This is true, with the qualification that the effect upon the water depends upon the kind of organic substance present. Here, we at once meet with difficulty; for we have not yet a satisfactory way of determining this point in every case. Quantity gives no certain indication; for, of two specimens of water, one may perhaps contain three times as much organic matter as the other, and the first be harmless, while the second may be positively poisonous. Neither the taste nor appearance is of much value. One English writer says that he examined some water from a well near a churchyard, that was loaded with organic matter of a most dangerous character, and yet was beautifully clear, and of a fresh, pleasant taste. We remember drinking water, ourselves, for several months, that was distinctly yellow, and yet perfectly good. Chemists have not yet been able to satisfactorily explain these differences, although one thing seems to be tolerably certain—that nitrogeneous substances are much more dangerous than non-nitrogeneous; and this brings us naturally to the most important of the questions relating to water and water-supply—the contamination of water by drainage and sewage. Many cities obtain water from rivers, along whose banks, towns, villages, and manufactories have been built; such water must become more and more impure and unwholesome every year. Any one who has stopped a short time in Cincinnati must be convinced of this. Buildings reach for some distance along the banks of the river (the Ohio), directly above the pumping works; while, farther up, numerous towns and villages are found, increasing in number and size every year. The drainage of all these places must, of necessity, deteriorate the water. The inhabitants may become accustomed to its use; but, judging from our own experience, it affects strangers very unpleasantly. In London, this evil has become very great. A large part of the metropolis is supplied with water from the Thames; and as the population along its banks has increased, its water has grown worse and worse. Water that may contain sewage never should be used. Nothing seems more likely to breed a pestilence or produce putrid diseases. Prof. Frankland, in a lecture before the Royal Institution, said:—"This hurtful matter is believed, on very strong evidence, to consist of spores or germs of organisms, which are capable, under favorable circumstances, of producing in man such diseases as cholera, typhoid fever, and dysentery." Such spores or germs will be better able to resist decay than unorganized

matter, and so can retain their powers of mischief for a longer time. In London, the matter of future water-supply has become of great importance, and, in connection with it, examinations and analyses of a large number of waters have been made. The attention of chemists has been drawn to the subject, and a thorough revision of water-testing and analysis is now going on. Wankhyn, Smith, Chapman, Frankland, Armstrong, and many others are engaged upon it; and, although some of them seem to have done, so far, more quarrelling than work, it is to be fervently hoped that they will place water analysis upon a surer foundation. Finally, we would say that, in testing the goodness of waters, any sample containing much organic matter should be at once condemned, even though it seems to be very good; and also that, in choosing a water for household purposes, it is important to see that it comes from a source that does not receive the drainage of houses, manufactories, swamps, or graveyards.

BAD HABITS OF THE ROBINS WHEN AWAY FROM HOME.

Editor Journal of Chemistry:—

I do not remember having seen it noticed in print, that the robins which leave their northern homes to winter at the South, fall, while there, into very bad habits.

They are exceedingly fond of the berries of the "Pride of India," a tree which is grown extensively for ornament and shade in some localities of Georgia and Florida. As this tree bears its fruit abundantly,—somewhat after the manner of the Mountain Ash in northern latitudes,—the birds collect upon it in great numbers, and, after feeding a while, many of them become so intoxicated that they can neither fly nor remain perched on the branches, but fall to the ground. Here they are picked up by the colored population, who esteem them very nice materials for "pot pies." If left undisturbed, the little creatures soon recover from the effects of their indiscretion; but, like some human beings, learning no wisdom from experience and consulting appetite at the expense of safety, they again return to the tree and indulge themselves with its delicious but dangerous fare.

We are not aware that any evil effects are experienced by those who eat of the birds thus captured; but may there not be some valuable *medical* properties in the fruit which thus affects the robins? S.

Dec. 1868.

Arts.

CLEANSING COD-LIVER OIL BOTTLES.

It is not unusual with the pharmaceutist to take back the empty bottles from consumers of cod-liver oil, and the corks being left out, the air causes the rapid oxidation of the small portion of oil left in each bottle, which becomes semifluid, and sometimes nearly solid, and is very troublesome to remove. This is also true of the exterior, which frequently is badly soiled with oxidized oil entirely solid. The junior whose duty it may be at intervals to cleanse the accumulated store of bottles preparatory to refilling, has frequently been worried by the tedious task. The most usual way is to boil the bottles in water containing soda, potash, or soft soap, which, when a large kettle is used, greatly facilitates the process, especially if the alkali employed is caustic; but this involves much space and a fire, and the handling of the bottles is difficult, so that the following plan will be found more convenient in the shop:—

Provide a pint of good *benzine*, half a pound of pearlash (or a pound of sal-soda), a quarter of a pound of lime, and half a gallon of boiling water. Slake the lime with a part of the water, and add it to the balance containing the potash in solution, and agitate them. These quantities for half a gross of pint bottles. Put about two fluid-ounces of benzine in a bottle, agitate it well, and in a few moments it will have dissolved all the oil, when it may be poured into another oily bottle, drained a moment, and then four ounces of the liquor potassæ cum calcæ is introduced (which should be warm), a good cork used, and the bottle well agitated. By means of a small sponge tied on a twisted wire, apply the alkaline liquid to the exterior of the bottle, standing in a shallow tin dish capable of supporting four or five bottles. Now pursue a regular order of sequence with the benzine and alkali inside and the alkali outside, shifting the benzine from bottle to bottle until it gets too foul for further use, and then the alkali from bottle to bottle, until it also is exhausted. The interior is soon cleansed, and a thorough rinsing with water completes the work. When the exterior of the bottles is very foul, it will be most convenient to apply the alkali externally *after* the benzine has been used, which enables the operator to see when all the oil is dislodged from the interior, when the alkali is subsequently used inside. Finally, rinse with alcohol.

Care should be used to reject and throw away the benzine solution of the oil before it gets so foul as to lose its thin consistence favorable to draining, which, when the bottles are dirty, will occur with the eighth or tenth bottle.

It is a good plan, when many bottles are thus taken back, to clean them partially with a little benzine before putting them away, and wiping the exterior with the same, which renders the subsequent labor very easy. These remarks apply to castor-oil and other oil bottles or cans. The latter often become very impure, so as to contaminate fresh oil put in them temporarily for transportation, and it would be well for *druggists* who habitually supply cod-liver oil to their pharmaceutical customers in cans, to make a rule systematically to drain them, and occasionally to cleanse them as above, observing to get them absolutely dry before using. Such cans should always be kept corked, and when the corks become foul they should be rejected. These remarks may be considered superfluous by many. For such they are not intended; but if a few only are benefited by the hints, they will have answered a useful end.—WM. PROCTOR, JR.: *Amer. Journal of Pharmacy.*

CHEMICAL LABORATORIES.

Prof. Frankland, in his address to the chemical section of the British Association, complains that the great science schools of the continent have no parallels in England, and contrasts the "discouraging way in which scientific studies are being introduced into our older universities" with the hearty co-operation which public opinion and governmental power yield to continental science. New and magnificent laboratories for chemical instruction have been erected at Heidelberg, Zurich, Bonn, Berlin, Leipzig and Carlsruhe, while the universities of Munich, Giessen, Vienna, and other cities, have scarcely less splendid, though not so recent, provision for the same objects. Some notion of the value set by foreign governments upon national scientific education may be gathered from the fact that the laboratory at Zurich cost a sum equivalent to \$68,000 of American coin, that of Bonn \$90,000, that of Leipzig \$58,000, and the estimates for the Berlin laboratory, with its seventy-four rooms, amount to nearly \$231,000.

Is it cause for wonder that both English and American students are still obliged to go away from home for thorough instruction in chemistry, to countries where science receives due nourishment and support? The Anglo-Saxon race is characterized by the activity of its individual members, and its forms of government leave as much as possible to the individual enterprise of the citizen. We hope the future will prove that democratic America, at least, is determined not to lag behind monarchical Europe in the earnest cultivation of science. The liberality and public spirit of our citizens must take the place of the paternal government. There has been a great progress in this direction. Men are more likely than they were to leave money for educational institutions; and when they outgrow the childish desire to found new and feeble colleges, and begin to endow adequately the old ones, Young Science in America will lift up her head without shame before her sisters beyond-sea.

In England, the second-hand blue postage-stamps are bought up for the indigo contained in the coloring. A Frenchman has just patented a process for extracting the indigo from blue rags.—*Journal de Chimie.*

HARD AND UNYIELDING CEMENTS.

To four or five parts of clay, thoroughly dried and pulverized, add two parts of fine iron filings free from oxide, one part of peroxide of manganese, one half of sea salt, and one half of borax. Mingle thoroughly, and render as fine as possible; then reduce to a thick paste with the necessary quantity of water, mixing thoroughly well. It must be used immediately. After application it should be exposed to warmth, gradually increasing almost to white heat. This cement is very hard, and presents complete resistance alike to red heat and boiling water.

Another Cement.—To equal parts of sifted peroxide of manganese and well pulverized zinc white, add a sufficient quantity of commercial soluble glass to form a thin paste. This mixture, when used immediately, forms a cement quite equal in hardness and resistance to that obtained by the first method.—M. SCHWARTZE, in *Chemical News.*

PHENOMENON RELATING TO HEAT.

MR. EDITOR:—In the hope of eliciting comment from some of your readers, I beg leave to present a theory in regard to a phenomenon of which I have yet seen no satisfactory explanation.

Every one must have noticed the peculiar *something* which begins to show itself over and around a stove when heated. The same thing is often seen on looking across the top of a chimney, or even the surface of a field, on a warm summer's day. Transparent as air, but really comparable to nothing else in nature, it is popularly supposed to be due to minute particles of dust, vibrating under the disturbing influence of heat; and we know at least one man, eminent in science, who is tenacious of the same opinion. To me it seems an easy matter to account for it on more philosophical principles.

It must be borne in mind that the phenomenon is visible only under certain circumstances. If the background, whatever it is, upon which we look, beyond the heated body, is made perfectly plane, or at least of any *uniform* shade or color, the appearance in question is at once arrested. Why is this? Evidently, to me, because the results of changeable refraction, on which the phenomenon depends, are no longer visible; the continual shifting in the apparent position of objects seen through the unequally heated, and of course unequally refracting atmospheric medium, being apparent only when such objects are dissimilar, and hence incapable of being blended, to the eye of the observer, with each other. Produce some irregularity of surface or of shade in the background, and at once the phenomenon reappears.

If I have made myself sufficiently plain for just criticism, I shall be pleased to see it in the *Journal.*

Yours truly, W. J. ORTON, M.D.

LISLE N.Y., Nov. 10, 1868.

RECTIFYING ALCOHOL BY MEANS OF GELATIN.

Whilst witnessing the manipulations of the Eburneum process in the studio of Mr. Burgess, at Norwich, Mr. Burgess mentioned a curious circumstance. When the gelatin and pigment forming the layer of eberneum is quite dry, it is coated with collodion to render it impervious to moisture. This operation, he noticed, always rendered the eburneum soft and limp, so that it required placing in the drying-box again. The greediness of the gelatin for moisture causes it to absorb the trace of water in the solvents of the collodion, and so become damp. This suggested to us a possible use for rectifying small quantities of alcohol, or removing water from collodion in which the use of imperfectly-rectified solvents has caused a tendency to give crapy films. Place a little pure gelatin in the spirit to be rectified. There is no danger of any portion of it dissolving, but it will absorb the water and gradually swell; it may then be removed, carrying the water with it. This will be found more convenient than the plan sometimes recommended of agitating with carbonate of potash, and after subsidence decanting.—*Chem. News.*

GLYCERINE IN MOULDING IN PLASTER.—Dr. Hoffman, in the *Journal de Chimie*, recommends the addition of a coat of glycerine to the ordinary soap coating used in moulding in plaster. For some time past, the separation of the proof from the mould has become more difficult, from the deterioration of soap.

Effect of Position on Sleeplessness in Acute Diseases.—Dr. Kennedy, of Dublin, alluding to the relation of our nervous systems to the great electrical currents of the earth, has often observed a beneficial effect from placing children in a north and south direction.—*Dublin Quarterly.*

The Tree-Beetle, or May-Bug, made Useful.—In Switzerland, an oil is extracted from beetles, and said to be "excellent for salad dressing and greasing machinery." In Prussia, a powder is made, which is mixed with food for fattening poultry. In France, a young chemist has obtained a coloring matter which is a fixed yellow, varying from a chrome to a golden. Each beetle yields several tenths of a grain.—*Journal de Chimie.*

Valuable Preparation of Glycerine.—Four parts, by weight, of yolk of egg, to be rubbed in a mortar with five parts of glycerine. This compound has the consistency of honey, is unctuous, like fatty substances, but is easily removed by water. Applied to the skin, it forms a varnish which effectually prevents the action of air. It allays the itching in cutaneous affections. It is unalterable, and can be exposed to the air for an indefinite period.—*British Med. Journal, from Phil. Journal of Pharmacy.*

Gold Quartz in New York State.—An auriferous quartz vein has been discovered near Clinton, N. Y. The vein is traceable on the surface for three thousand feet, and varies in width from six inches to one foot. The quartz is bluish, and a portion of it next to the walls decomposed. It is well defined, and pitches at an angle of seventy-five degrees. An assay of samples of the quartz rock shows that it contains $15.45 of gold to the ton, and about 20 per cent of silver.

The Russian government has granted a concession for the construction and working, within the Russian territories, of a direct line of telegraph between London and India, to Messrs. Siemens Brothers, of London, and Messrs. Siemens & Halske, of St. Petersberg and Berlin. The concession is granted for twenty-five years, dating from the commencement of the line's effective working.

Artificial oil of bitter almonds is manufactured from the benzole of coal-tar. A fine stream of benzole and another of fuming nitric acid are allowed to run together in a worm kept well cooled. The liquids react on each other on coming in contact, heat is disengaged, and the artificial oil collected at the end of the worm is first washed with water, then with a solution of carbonate of soda, and lastly again with water.

Preserving Wood.—The following method of preserving wood has recently been patented in England:—A solution is made of 10 pounds of powdered potassa and 10 pounds of powdered lime in 50 gallons of boiling water, and another of 150 gallons of cold water and 40 pounds of sulphuric acid. These two liquids mixed together form what is called compound No. 1. Next, 50 gallons of crude petroleum, 40 pounds of asphaltum, 30 pounds of powdered lime, and 20 pounds of zopissa are boiled together, and mixed with a pint of sulphuric acid, to form compound No. 2. The timber to be preserved is immersed in compound No. 1 for a quarter of an hour, and then dried for a day or two, and afterwards it is, by the aid of a tar-brush, coated on all sides by compound No. 2.

Action of Iodide of Methyl upon the Vegetable Alkaloids.—One of the most interesting of recent discoveries connected with physiological chemistry, is that made by Drs. Brown and Fraser, of the change in the properties of the vegetable alkaloids, brought about by directly adding to them iodide of methyl. They have so far examined iodide of methyl with strychnine, nicotine, morphia, brucine, codeine and thebaia. As an example of their results they have found that in the strychnine compound the toxic properties of the alkaloid are diminished about one hundred and forty times, and that its physiological action is of an entirely different character. Instead of the spasmodic convulsive effect of strychnine, this compound, like curare, produces paralysis of the end organs of the motor nerves, the muscles remaining flaccid. Combining iodide of methyl with the other alkaloids affects them in a similar manner. In the case of morphine, its convulsive power is destroyed but its soporetic effect remains.

Agriculture.

ARTIFICIAL MANURE.

The following address to the chemists of Great Britain, appears in a recent number of the *Chemical News*, and is signed by William Little, in behalf of the South Lincoln Tillage Association. The views presented and statements made are such as ought to engage the attention of every farmer in the United States.

"To the Chemists of Great Britain.

"Gentlemen,—I take the liberty of addressing to you a request of the greatest importance to the progress of agriculture in this country; and my excuse for taking this liberty is, that any opinion in reference to the science of agriculture that bears the sanction of your authority will be accepted by farmers and others, as not only of the highest order, but in the most perfect faith of its being given sincerely and purely in the interest of agriculture.

"The request I have to make to you—not alone in my own name, but in the name of an association formed to protect and promote agriculture—is that you will favor us with your opinion on the principles we have adopted in the choice and purchase of artificial manure.

"In this country the trade and manufacture of artificial manure is assuming gigantic proportions. At certain seasons of the year our corn exchanges are inundated with makers and their agents; every kind of 'specific' in the shape of manure is offered for sale by all sorts of people and for every kind of crop; and I need scarcely inform you that, in proportion as these artificial manures are good and useful, so are they associated with an alarming amount of deception and fraud; so much so, indeed, that unless some very active measures are taken to expose and counteract this evil, the employment of the good and useful manures will be seriously affected, and the progress of agriculture seriously checked.

"We are doing all we can to meet this large and growing evil, by the formation of an association of practical farmers, and hope by combined effort to secure to agriculture all the advantages that science has bestowed upon it, and at the same time protect ourselves against the various costly and comparatively useless 'nostrums' and fraudulent mixtures that are prepared by mean and insignificant makers under the various titles given to artificial manures.

"That an association such as we have formed was most urgently required will be seen by the following facts:—Only a few months ago I was paying to a most respectable firm £6. 10s. per ton for manure, which I am now able to purchase, of even better quality, at £4. 2s. 6d.; but this reduction in the cost of manure is not, after all, the most important fact. It is still more satisfactory to know that, at all times, we may rest assured that through the watchful agency of our association any manure received will certainly have the quality and strength bargained for. Just to show the great change and progress that have been made in the manufacture and supply of phosphatic manures within a few years, I will quote from a card which gives the analysis and value of manure as supplied by one of the most honorable and respectable manufacturing firms. This manure was stated by six eminent chemists to contain an average of 18 per cent of soluble phosphate, and was valued at between £9 and £10 per ton. Now, by the rule of three, if 18 per cent costs £10, the value of the manure as now supplied through our association, and containing 26 per cent, should be something over £14 per ton. Again: the value of soluble phosphate was estimated at £35 per ton; at this moment, the pure soluble phosphate contained in our manure, and delivered free to our members, costs about *twelve pounds* per ton; but is it unreasonable to expect a still further reduction in the price, and improvement in the quality of these manures? Hitherto the great source from which our phosphatic manures have been procured has been the wonderful coprolite beds of Cambridgeshire, Bedfordshire, Suffolk, etc.; but recently there have been discovered phosphatic rocks in Spain and Canada, containing not less than 80 per cent of phosphate of lime. Surely it is only a question of time when these immense stores of phosphorus will be imported into this country in quantities without limit, and thus enable us to restore, not only to our arable soils, but to our grass lands as well, the phosphatic elements which for so many years have been taken from them, and the loss of which I have no doubt has been one of the chief causes of the exhaustion of our soils; and is it not probable that this immense trade will shortly fall into the hands of our large sulphuric acid makers, who will use these minerals as a convenient means for disposing of thousands of tons of sulphuric acid?

"An important principle in the conduct of our association is this—no exclusive or individual interest or profit can exist; whatever advantage we can secure by co-operation is entirely for the benefit of the general body of our members. Another important principle is that we purchase only one kind of artificial manure—'Superphosphate of Lime;' and we do this in obedience to what we believe is nature's simple and beautiful law,—Return to the soil in some shape that which you take from it. We say the crew yard with the food consumed by stock, together with a system of cultivation that enlarges and deepens the lungs of the soil, thus enabling it to inhale and more completely nourish itself by the action of rain and the atmosphere, will in general supply every thing else that can be *profitably* employed. Consequently every shilling that a farmer has to spend in artificial manures is spent with the greatest advantage in the purchase of phosphatic manures only.

"We do not deny that 'special manures' may be useful in 'special cases,' but such manures must always be expensive, since there can be no competition in their supply; each maker has his own secret or patented process, in neither of which have we any faith; therefore the cost of such mixtures to the consumer must be just what the maker may be inclined to charge; but we further protest against farmers purchasing or using at any time artificial manures of the composition of which they are completely ignorant, and by so doing put themselves blindly into the hands of the manure-makers. Every farmer should know what he buys, and for what purpose; without this knowledge he is no longer a farmer, but simply an agent—the manure maker usurps the intelligence of the farmer; besides such a position at all times exposes the farmer to the grossest deceptions and frauds. These very serious objections cannot occur in the purchase of phosphatic manures; their composition is well understood, and a large amount of experience has proved the many ways in which they may be profitably employed; they are besides prepared by numerous makers, and are at all times under the control of the 'Golden Economic Law' of free competition—supply and demand. In the purchase of these manures the farmer knows exactly what he buys, and by becoming a member of an association such as we advocate, he insures for himself a phosphatic manure of certified quantity at the very lowest cost.

"I hope that I have clearly explained the purpose of our association, in its chief principle, which we earnestly advocate, viz., the use and function of one kind of artificial manure. We believe we are only putting into practice the laws and opinions which have been long advocated in the many works and contributions to the science of agriculture. Should these observations be successful in eliciting the opinions of chemists, I hope they may be of a thoroughly practical character. It will be of no use to say certain materials would be valuable additions to the simple phosphatic manure unless they can be procured in any quantity and at prices that will make it worth while. Manure-makers are too ready to talk of the absence of nitrogen or ammonia, potash, magnesia, etc.; but supposing these substances to be necessary or useful, can they be purchased to pay, and does not Nature supply the most important of them—nitrogen—free of all cost, if man will only perform his part in the preparation of the soil? Do we not always find, when we read Nature aright, that all the large requirements for the sustentation of vegetable and animal life are ever at hand? If this is not the case, why have we six million pounds of nitrogen constantly pressing on every acre of land? and why have the wonderful discoveries of the spectroscope revealed to us that the salts of the ocean, especially soda, is to be found everywhere, even on the tops of our highest mountains?

"In conclusion, allow me to observe that, should the objects of our association have the valuable support of your favorable opinion, it will then only remain for time, patience, and perseverance to complete our task and to make our association an example to be usefully and

profitably followed by every other part of this great agricultural country. I have the honor to be, Gentlemen, in the name of the South Lincoln Tillage Association, your obedient servant, WILLIAM LITTLE."

THE APPLE CROP.

We are glad to find that an interest is still felt in the apple crop, although it has been so sadly deficient for several years past. It may flourish again, and afford us a large surplus for foreign markets. Wholesome, nutritious, and palatable as the apple is, thousands of families among us have undoubtedly been without it—unless in the most limited quantity—for four or five years past. During this period, less attention has been paid to the setting of new orchards; those of middle age have been greatly neglected, and old trees have been cut down by hundreds and given to the flames.

Another and prime cause of rapid decay and loss has been occasioned by thoughtless, careless, and injudicious pruning. Few of the duties of the farm are so badly performed—bad in the *manner* in which it is done, and in the *season* usually selected for the operation. Trees are living things, and must be treated as such. Their young bark is as vulnerable to hobnail boots as the back of the hand, and as easily mutilated by a dull saw or knife. No skilful surgeon would amputate a limb with dull instruments, or leave the bleeding wound exposed to the air; but many farmers who have pruned for forty years, and think they "know a thing or two about it," do both.

Every wound made in pruning that is half an inch across should be covered. If the tree is vigorous it will probably grow over without help, but covering greatly aids the effort of the tree in healing up any damage done to its outer garment. The best covering is gum shellac dissolved in alcohol; but as alcohol is quite expensive at present, paint of any color will answer the purpose, if care is used not to let it get upon the bark.

There is need of but very little pruning where an orchard has been properly managed from the start; no large limbs will ever need to be taken away, unless broken by winds or injured in some other way. *Prune but little*, is a good motto, but prune *annually*. Do not allow suckers or limbs that are crossing each other to grow several years before they are removed. Suffer the shoots that start out in spring to remain until the leaves have fallen in autumn, and then cut them smoothly off. The tree needs them for a time, and Nature, ever ready with a helping hand, sends them out to aid the leaves of the top in elaborating the sap and increasing the whole growth of the tree.

As to the best time for pruning apple-trees we have not a particle of doubt. From a long series of personal experiments running through twenty years, from reliable books recording the experience of others, conversations with practical men, and an extensive examination of orchards, we are fully of the opinion that the *middle of the month of June* is the most appropriate time. But as the ground is covered with grass or other crops at that season, and hoeing and other work is pressing, it is not always convenient to engage in it then. The next best time is in *October, after the trees have shed their leaves;* and this may be extended into November or December, if the operator can keep himself sufficiently warm to do the work well.

Where we have carefully pruned at either of these times, it has seldom been followed by a flowing of the sap and the black discoloration of the bark which so often follows spring pruning. The wounds become dry and hard on the surface, a lively growth commences in a few weeks if the pruning is done in June, and early in the following spring if the work is done in the fall, and the tree seems to sustain no check or injury whatever.

The question may be asked, *Why* is it best to prune at the seasons mentioned? We answer, Because the tree is then *in a comparative state of rest*. The sap has ascended through the sap-vessels in the trunk, followed out the extremity of the smallest twigs, and into the leaves, there to be worked over by the wonderful alchemy of Nature into thicker and more substantial substances. This thickened, or inspissated sap, as it is called, then passes down directly under the bark, and gives the trunk and branches their annual growth in diameter. Now, then, when the tubes or sap-vessels are nearly empty, or are comparatively so, is the time to prune. This occurs, for about fifteen days in midsummer, and after the trees have cast their leaves in autumn, until a succession of sunny and warm days sets the sap in motion again. Such days occur some time in midwinter, and it would then be unfavorable for pruning.

In pruning in June or October the saw soon becomes so much covered with gum that it is moved with difficulty, and it becomes necessary to wash it. This has never occurred in March, April, or May, in our experience. The sap is then thin and abundant, and the saw remains clean and bright.

In pruning, the aim should be to keep the head of the tree open to the air and light, and free from limbs that are crossing and rubbing against each other. Cut out these and the occasional dead limbs which may be found, and the orchard which has been well managed will need little more in the way of *pruning*. Each tree should be examined annually, and whatever is needed for it done.

N. E. Farmer.

SHELTERING ANIMALS.

The old Connecticut teaching was, that it renders young animals tough to confine them in the open field with the snow-banks for their bed, the starry canopy for the covering of their shed, and a rail fence for the side. But, experience assures us that such a system of management, with stock of any kind, is the most expensive mode of keeping domestic animals that can be adopted; because, when they are not protected properly from the pelting storms of our Northern winters, they will not be in as good flesh. A hundred pounds of fat and flesh on a good cow are worth more—pound for pound—than a hundred pounds of prime butter; because, if a good cow lose one hundred pounds of fat and flesh during the foddering season, Nature will make a desperate effort during the grazing season to reproduce the lost portions of the animal system; and the food required in making these secretions would otherwise have been converted into milk and butter-producing material. The same fact is true in regard to the fat and flesh of young cattle and sheep. When young cattle are maintained on an allowance of food too small to supply the requirements of their bodies, they lose flesh; and when they are falling away, it is quite impracticable for them to develop the proper form and symmetry of their bodies. Therefore, the farmer who requires animals of any kind to draw upon the flesh that has accumulated during the growing season, for the purpose of keeping them alive during the inclemency of the weather, will find that such a practice is not only exceedingly expensive, but ruinous to the health and vigor of his stock.

Sheep that are allowed to lose ten to twenty pounds of fat and flesh, each, during the winter months, cannot be expected to yield as many pounds of wool as if they had been properly fed and protected, and their fat and flesh retained.

Teams are often allowed to lose one or two hundred pounds of flesh during the foddering season, which cannot be reproduced at a cash expense of less than ten to fifteen cents per pound. Saying nothing of the loss incurred, or the expense of reproducing a hundred pounds of flesh, a heavy team for most agricultural purposes is far superior to a light one. A horse that weighs ten hundred pounds will suffer much less fatigue while hauling a heavy load over a rough road than another animal that weighs only eight hundred pounds. This may be inferred from the fact that the *momentum* of a heavy horse overcomes resistances which a light horse must meet with *muscular* force. These hints, we trust, will be sufficient to induce such care of teams that none of their flesh or muscle shall be lost.—*N. Y. Observer.*

ESSAY UPON FERTILIZERS.—It having been stated in several papers that the prize for essay upon the use of special fertilizers, had been awarded us by the Essex Agricultural Society, many inquiries have been made regarding its publication and where it can be procured. It will appear in the *Transactions* of the Essex Society in February, and we shall endeavor to find a place for it in the February number of the *Journal.*

Boston Journal of Chemistry.

BOSTON, JANUARY 1, 1869.

THE JOURNAL.

Our patrons will please remember that the new volume, or Vol. IV. of the *Journal*, does not commence until July next. To new subscribers we are sending the back numbers, so as to have all subscriptions expire together at the end of the present volume.

Our present design is to enlarge the paper, and modify its form, so as to render it more elegant, useful, and desirable. We shall make it a journal of *twenty-four* pages, reducing the size so that it will be more convenient for reading and binding. The price also will be raised to *one dollar* per annum. It will still be, as it has been in the past, *the cheapest scientific journal published in the world.* Our next issue will contain the Prospectus for the New Volume.

ERRATA.—In the article upon "Zodiacal Light" in our last issue, page 64, column 2, line 66, for "exterior" read "extensive," and in column 3, commencing with line 21, read, "But by actual observation the zodiacal light is found to always have the greatest breadth and intensity at F and G, and to decrease both in breadth and intensity from F toward H, and from G toward I; and under ordinary circumstances," etc., instead of as it now stands.

ERRORS AND ABSURDITIES.

The blunders made on scientific subjects in the newspapers of the day, and in many of the most popular elementary text-books, are often very ridiculous. During the past season, a little paragraph went the rounds of the papers, not excepting some of the best of our city journals, informing the public that mosquitos will not enter a room through an open window, if a rag "saturated with *carbonic acid*" is hung up in the window. A rag soaked for some hours in strong moonshine would probably answer the same purpose. The original statement was, doubtless, "*carbolic* acid," and it is strange not one of the editors who copied the paragraph was able to correct the error.

The makers of school-books are too frequently men who have no knowledge of the sciences which they attempt to teach, and who, in their "paste-and-scissors" compilation from better authors, blunder into very preposterous statements. One of the most popular school "Chemistries," in describing the conversion of starch, woody fibre, etc., into sugar, says: "Indeed, Prof. Pepper

speaks of eating a fine quality of grape-sugar made out of an old flannel shirt he had outgrown." What Prof. Pepper *does* say is this: "If, however, oil of vitriol is first added to the *linen* rags, then the rags are converted into sugar (the author has seen a specimen made of an old shirt)," etc. The American book-wright was not satisfied to take this simple statement, but must attempt (as he has done in many other cases of the kind) to embellish it. He must make it "a fine quality" of grape-sugar; and Prof. Pepper must not only see it, but eat it; and, to improve the joke of the thing (but unluckily at the expense of the science), it must be an "old *flannel* shirt" that has undergone the sweet metamorphosis. The absurdity of trying to convert *wool* as well as linen into sugar did not occur to him.

The same book gives "analine" three times in seven successive lines instead of *aniline*, and "coffeine" for *caffeine*, and adds "anguintum" as a synonym for *mercurial ointment*. In speaking of chemical names, it states, that "the equivalent of oxygen combined in the base is omitted," and gives three illustrations of the omission — sulphate of *soda*, sulphate of iron, and sulphate of *lime*. It will be seen, that only one out of the three is in point. The author derives the name *protein* from the Greek *proteno*, "I am first," but discreetly refrains from any attempt to show the connection in meaning between the word and its Hellenic source. Of course, every school-boy knows, that *protein* takes its name from the old god Proteus, who used to assume so many different forms in order to dodge the troublesome people who wanted him to play the prophet; and that the substance (if indeed there be such a substance) is so called from the protean forms in which it appears.

These are but a few out of dozens of similar errors in a single school-book (and a book used even in a school of so high rank as the Girls' High School in Boston), but they will serve to show that there is a sad want of *accurate* knowledge on scientific subjects, even among those who presume to write on such subjects for the instruction of others.

AERONAUTICAL SCHEMES AND THEIR FEASIBILITY.

There is a popular impression that all attempts to navigate the aerial ocean which surrounds our globe are wild and visionary. Scientific men have, for the most part, denied the possibility of constructing balloons that should have sufficient buoyancy to sustain the weight of the engines and other machinery, with the supplies of fuel, etc., which would be the necessary outfit of an air-ship. But recent investigations appear to show that the prospect of aerial voyages, with other motive power than the capricious winds can supply, is not a hopeless one. The Aeronautical Society of London has done a great deal in this direction, and gives promise of doing a great deal more in the future.

This society offered a prize (of one hundred guineas, if we remember aright) for the engine best adapted to aeronautical purposes. A number of very ingenious machines were offered in competition for this prize; and among them was one which weighed only sixteen pounds, and had a capacity of one horse power. One of the engines was propelled by a composition similiar to that used for filling rockets.

Those who have denounced all schemes of this kind have known scarcely any thing of the mechanical conditions on which flight depends. Scientific men have demonstrated that birds do not, in flying, exert the prodigious force usually ascribed to them, but when once risen from the earth, and started in a horizontal direction they can sustain themselves in the air by a very moderate exertion. They have shown also that large heavy birds can be sustained in rapid flight by wings very small in proportion to those of lighter and smaller birds. Thus, a pigeon weighing ten times as much as a sparrow, has only half the *proportional* surface of wing. The stork weighs eight times as much as the pigeon, and has only half the spread of wing. The Australian crane, with three hundred and thirty-nine times the weight of the sparrow, has but one seventh the wing-surface The same is true of insects. The gnat weighs ninety-seven thousand times less than the pigeon, with forty times the proportional wing-surface, and three million times less than the Australian crane, with one hundred and forty times the wing-surface. These and many similar facts prove that, to carry great weights at great speed through the air, it is *not* necessary to have immense pinions with a spread proportional to the weight, and requiring powerful engines to work them. The *possibility*, therefore, of aerial locomotion by flying machines capable of carrying great weights must be admitted by all; though it may be a long time yet before the thing is actually accomplished on a large scale.

DIVISIBILITY OF MATTER.

The communication of Dr. Merrick, which appeared in the last number of the *Journal*, is calculated to awaken some inquiry upon an interesting point in chemical theory. This theory is based upon the supposition that all substances are made up of atoms, and it is inferred that when any substance is in perfect solution it is resolved into a condition representing a separation of the atoms. Each atom is supposed to be indefinitely small. What may be the actual dimensions of such particles of matter, is a question no one is capable of answering. It is difficult to conceive of ultimate atoms; in fact we do not understand how such a thing can be, and when we speak of the separation of a body, by being diffused throughout a solvent, we are remarking upon a physical condition of matter of which we know but little. The belief is entertained by many distinguished chemists, that atoms have no dimensions, in fact that no such thing as an ultimate atom exists. What we call atoms are truly mathematical points, whence proceed attractions and repulsions, and upon which all chemical changes depend. How small must an atom of bromine be, when by placing a single drop in a *million* drops of water, we can detect its presence by a class of reagents recently discovered! But the point brought out in Dr. Merrick's inquiry is, whether there is not a limit to the divisibility of matter? If the drop of bromine is placed in *two* million drops of water, we lose all trace of it; no known reagent is capable of demonstrating to our senses its presence in the water. What is its condition in the two million drops of water? Is it split up into ultimate atoms, and then so widely separated by the mass of the solvent as to be unable to respond to the action of the disturbing chemical test? If we regard a drop of bromine but an aggregation of positive atoms, and these having fixed dimensions, some idea of its condition in the two million drops of water may be formed. We can conceive of the atoms floating about, their proximity to each other depending upon the amount of the solvent in which they are held or diffused. Whether this view be strictly correct or not, it certainly harmonizes with nearly all the facts observed in chemical manipulation, and since we cannot better express our ideas of the nature of a solution, we may as well adopt it. There is manifestly a limit to the divisibility of matter.

The largest laboratory in the world is at Berlin.

LUMINOSITY OF FLAMES.

Sir Humphrey Davy first propounded the theory that the light of flames was caused by the presence of incandescent solid particles. Professor Frankland gives some reasons for doubting the correctness of Davy's hypothesis. For instance: metallic arsenic burning in oxygen is intensely luminous, yet both metallic arsenic and the result of its combustion (arsenious acid) are volatilized at a temperature much below that of this flame. Every one knows how brilliant is the light of phosphorus burnt in oxygen, but since phosphoric acid is volatile at a red heat, it is evident that it cannot be due to the presence of solid particles. Again: bisulphide of carbon vapor burning in oxygen or nitric oxide gas, is remarkably luminous; yet it would be absurd to suppose the existence of any solid body in such a flame. For these and other reasons Prof. Frankland concludes that the luminosity of gas and candle flames is due to radiation from dense, but transparent hydrocarbon vapors.

FRAUDULENT KEROSENE.

The 29th section of the amended U. S. Internal Revenue Laws relating to illuminating oils, is as follows: —

SECT. 29. *And be it further enacted*, That no person shall mix for sale naphtha and illuminating oils, or shall knowingly sell or keep for sale, or offer for sale such mixture, or shall sell or offer for sale oil made from petroleum for illuminating purposes, inflammable at less temperature or fire test than one hundred and ten degrees Fahrenheit; and any person so doing shall be held to be guilty of a misdemeanor, and on conviction thereof, by indictment or presentment in any court of the United States, having competent jurisdiction, shall be punished by a fine of not less than one hundred dollars nor more than five hundred dollars, and by imprisonment for a term of not less than six months nor more than three years.

This is clear and explicit. Under the act the whole class of mixers and adulterers, wherever they may be found in the United States, can be arrested and promptly punished. The sellers of recipes for naphtha fluids, the travelling villains who are jeopardizing the lives of thousands, the mixers and dishonest dealers, all should be brought to feel the full force of law. To our readers we say: Do not let one of them escape.

QUESTIONS AND ANSWERS.

M. M. M. "What is the best material for coating tools and steel instruments to keep them from rusting?"

Answer. A preparation composed of three parts lard and one part rosin, melted together.

A. B., *Cincinnati*. — "Can you give me a recipe that will stick labels upon tin?"

We find the following in the *Druggists' Circular*: "Dissolve two ounces of common resin in a pint of alcohol, and allow nearly all the alcohol to evaporate, after coating the tin, before applying the label."

H. T. T. — "How can I repair India-rubber boots so that they will not leak?"

Cover the hole with a patch cut from another boot, using a cement made by dissolving pure India-rubber in either bisulphide of carbon or benzine. Use benzine made from coal-tar, not the hydro-carbon liquid from petroleum.

M. J. R. — 1. The percentage of potash in wood ashes is, by weight, as follows: —

Oak	12	Pine	13.6
White beech	19.22	Wheat straw	10
Red "	16.3	Rye "	19.47
Birch	16	Potato vines	4.2
Fir wood	25.7	Bean "	33
" charcoal	50	Pea "	27.8

The branches and bark of trees give a larger per cent of potash than the wood, probably because they contain more sap, which holds the potash in solution. 2. Crude potash is certainly a valuable fertilizer to apply to lands; but it is much cheaper and better to apply the ashes when they can be procured. 3. Our price for making an analysis such as you mention is twenty-five dollars.

SPECTRUM ANALYSIS OF A COMET. — Mr. Huggins, well known for his labors upon the spectra of stars and comets, has made an examination of the spectrum of the second comet of 1868, which turns out to be more satisfactory than any he has before made. In the first place, he finds that the spectrum is not continuous, but consists of three broad bright bands, and is therefore due to a gas. In the second place, noticing that this spectrum resembled very closely that of carbon (obtained by passing a spark through olefiant gas), he was led to compare them one with another, and found that they exactly coincided. This would seem to prove that carbon existed in this comet in a state of vapor. Such a case is irreconcilable with the laws governing terrestrial phenomena.

☞ We have received quite a number of valuable books for notice from publishers, but owing to the illness of the Editor of the *Journal*, they must remain over until our next issue.

In our last number, we published a recipe for a new solder of aluminum. Since then, we have received a letter from Dr. Geo. O. Starr, of New York, claiming that Dr. Alfred Starr is the inventor of the same, and has obtained letters patent upon it.

Medicine and Pharmacy.

FLORIDA AS A WINTER RESORT FOR INVALIDS.

REV. DR. SEELEY, of Haverhill, Mass., who has spent considerable time in Florida, sends us the following interesting and important statements regarding the climate:—

Editor Journal of Chemistry: —

I was much interested in the papers of Dr. Mattocks, published in the September and October numbers of your *Journal*, on "Minnesota as a Climate for Consumptives." I do not feel qualified to judge as to the correctness of all the theories stated by Dr. M.; but they seem very reasonable, and it is pleasing to think there is, at least, a *chance* for the consumptive to gain a prolonged lease of life and physical comfort by residing in Minnesota.

I would not have it understood that what follows is intended to controvert the statements of Dr. Mattocks; and if I thought the effect would be to divert any one who might be benefited by a visit to Minnesota from the purpose of going thither, I would withhold this communication.

But it is possible that there are invalids for whom the extreme cold of that State would prove too severe. This can be decided, not on general principles, but by the family physician, who is acquainted with the peculiarities of the case and the idiosyncrasies of the individual concerned.

If there be instances in which the medical advisers think the climate of Minnesota might prove too severe, it is well for such that the neighborhood of the St. Johns River in Florida presents a climate of an entirely opposite description, and one which numerous and long-continued experiments prove to be exceedingly favorable for those who have weak lungs.

This noble stream rises about midway between the 27th and 28th parallels of latitude, and, running in a northerly direction, winds through a carbonaceous and sandy soil, which is covered, for the most part, with pine forests, at an average distance of twenty miles from the Atlantic coast, until it reaches its extreme northern point near Jacksonville. Not far below (i.e. north of) this city, the river sweeps round to the east and empties into the sea at "Fort George Island," a few miles north of the 30th degree of latitude, and twenty-five miles from Jacksonville.

The St. Johns thus extends from a perfectly tropical climate, which is never reached by the frost, and in which the orange, lemon, citron, banana, pine-apple, and other tropical fruits grow luxuriantly, until, at its northern extremity the temperature, during the two months' winter, resembles that of a New England October. The flowers disappear, the temperature frequently falls sufficiently low to form ice on the surface of water left out of doors during the night in tubs or pails, and a good blazing fire on the hearth is quite desirable at morning and evening. But even here the orange, lemon, fig, and olive are cultivated with great success, the degree of frost ordinarily experienced doing them no injury; * and the evergreen foliage of the trees and shrubbery is a pleasant indication that summer has withdrawn to no very great distance.

It must not be overlooked that, sometimes, changes of temperature occur which (considering the latitude) may be regarded as both sudden and severe. So far as the writer's observation enables him to judge, these changes are due to easterly winds setting in from the sea. Nevertheless the distance inland of the St. Johns, at Jacksonville (and, indeed, all along its banks) is such that the inconvenience caused by these sea-changes must be much less than it is on the coast, or even at such a place as St. Augustine; and, at the same time, the cold humidity of those places in the more westerly portions of the State, which, like Tallahassee, are on a tenacious, clayey subsoil, is not experienced.

Among the advantages afforded by the St. Johns must be reckoned the ease and facility with which the several towns and settlements on its banks can be reached and the varieties of climate they afford. One can take a steamer at New York and in three days be at Savannah, cost of passage and fare twenty-five dollars. Thence lines of steamers run to Jacksonville and up the St. Johns almost daily; the time from Savannah to Jacksonville, about eighteen hours, cost of passage and fare ten dollars; and farther up the river in like proportion.

Board can be secured at reasonable rates (say about fifteen dollars a week) at almost any of the settlements, hotels, and boarding establishments on the banks; the best places thus far being at Jacksonville, Hibernia (Fleming's Island), Green Cove, and Enterprise.

The invalid can thus select the climate which best suits his case — whether that of a perpetual summer at Enterprise, two hundred miles up the river, or the cooler temperature of Jacksonville, near its mouth, or that of some place between the two. Wherever he goes he will find many northern people; some, like himself, in search of health, others taking advantages of the openings for business which are numerous in that almost virgin territory, and all of them, as well as many of their southern fellow-citizens, attentive to visitors, courteous, and hospitable.

All things considered, the undersigned is disposed to think the region above mentioned is preferable to Cuba, Nassau, or any of those localities in the South of Europe which have been most esteemed as winter resorts for invalids; and is confident that as its merits are made known multitudes of those who are affected with weak lungs and throat affections will escape from our harsh northern climate and spend the winter months on the attractive and health-giving banks of the St. Johns.

It should be added that those who reside in the locality and who are best qualified to judge what is advisable, deem it necessary to remain in Florida not only through an entire winter, but also during the following summer and winter, in order to secure the highest advantages afforded by the climate. There are those who, finding it impossible to spend a winter at the North, have become permanent residents in the neighborhood of the St. Johns; and they declare themselves as well pleased with the *summer* as with any other season of the year. Meanwhile they enjoy excellent health in all respects.

If convenient, the invalid, escaping from the approaching cold of the North, should stop a while at Savannah, until the temperature of Florida shall be somewhat modified by the autumnal change, and then proceed to Jacksonville, or farther South, as his plans or his comfort may dictate. In *leaving* Florida great precaution should be taken. In no case should an invalid proceed directly to the North, except in summer. The transition from one temperature to another is so great at other seasons as to shock the system and lead to evil results. The better way is to leave the St. Johns in the latter end of April and spend the month of May in Savannah, where the climate is then most delightful; and so arrange as to reach the North in June, after the lingering chill of spring has finally taken its leave.

The undersigned has known invalids who in this way have prolonged life for years; some who have received permanent benefit, and others who are evidently improving, with fair prospects of recovery. One gentleman met in Florida (a New York merchant), said his lungs were, and for twelve years had been, completely pervaded with a severe bronchial inflammation, and that he had lengthened out his life for that period by spending his winters in Florida, and keeping in a summer temperature while there and in his journeyings to and fro. A lady (resident of New Jersey), also met in Jacksonville in the winter of 1866–7, and who was then afflicted with a most distressing cough and the other usual symptoms of consumption, and who took these precautions in passing to and from the South, was again in Florida during the winter of 1867–8, much improved in health, and apparently with a fair prospect of recovering entirely. A member of the writer's own family, having annually suffered from attacks of acute bronchitis for several years, was left, in the spring of 1866, with a severe cough which no remedies sufficed to check. Several distinguished physicians (among them Dr. Bowditch, of Boston) pronounced the case one of incipient phthisis; and, as a forlorn hope, it was resolved to try a winter's residence in Florida. The place at first selected was Tallahassee, but this was soon exchanged for Jacksonville. Here the cough began to improve after a few weeks, and the patient reached home in June apparently cured, with no marked symptoms remaining or since returning.

The undersigned can not close this paper without expressing his obligations to Dr. J. D. Mitchell of Jacksonville, to whose skill and attention the cure must, in part, be attributed. Dr. Mitchell is a northern man whose own health renders it necessary for him to reside in the South, and he may be commended to all who visit that locality in search of health and in need of professional services, as a skilful physician and a Christian gentleman.

R. H. S.

* In 1836 the frost was so severe as to kill the oranges and lemons; but since then no such extreme of temperature has occurred; and now the orange groves are becoming quite numerous and flourishing.

IMPORTANCE OF A KNOWLEDGE OF CHEMISTRY TO THE PHYSICIAN.

As with a knowledge of anatomy, so too with a knowledge of chemistry and materia medica; they must be equally minute. The effects of poisons upon the system, the influence of various remedies upon the various secretions must be minutely investigated, so as to be thoroughly understood. To obtain this knowledge, requires the most careful and devoted study, and can only be obtained by constant labor in the chemical laboratory. So, too, in regard to the actions and effects of the various drugs and medicines upon the human frame. A knowledge of them all must be equally minute, and can only be obtained by a careful study of the materia medica, and in order to comprehend it, a knowledge of botany, is also necessary. As an instance of the necessity of this knowledge, and its importance, allow me to refer to a case which recently occurred. Summoned in haste to a fashionable hotel, to see two gentlemen who were supposed to be dangerously intoxicated, I found them with feeble pulse and the greatest muscular prostration, with dilated pupils and partial loss of vision, in a recumbent posture, apparently perfectly well, with the exception of the feeble circulation and want of muscular power before mentioned, with the intellect unclouded, and exhibiting no signs of intoxication. In an erect posture the heart almost ceased to beat, and they fell almost lifeless to the ground, exhibiting, in fact, all the symptoms of poisoning with prussic acid. Both were affected in a similar manner, but the one more seriously than the other; the symptoms being of the same character, only differing in degree. The question now was, how had the prussic acid been administered; whether by accident or design? A friend present, who was perfectly sober, stated that he had dined with them, and that previous to the dinner, they were in perfect health; that they had all drank of the same wine, in apparently nearly equal proportion; and as he was entirely unaffected, that what they had drank could not have been the cause of their present condition. He stated that these two gentlemen who were sick, had dined upon partridge, whilst he had partaken of a different dish, and that the one whose symptoms were the worst, had eaten more of the partridge than the other, and the symptoms began to develop themselves in both gentlemen, very

nearly at the same time, about forty minutes after the commencement of their dinner.

Finding no source of poison in any thing else that had been partaken of by them, I naturally inferred that it was obtained from the partridge. How did it get there? Happening to be a long winter, when there had been seven weeks of continuous snow, and the ground constantly covered, these birds had been prevented from obtaining their ordinary food, and had been compelled to feed upon the berries of the laurel; therefore, their flesh had become charged with the potent poison of prussic acid, which in a minute quantity, is found in the berry of the laurel. Then looking at the characteristic symptoms presented, paralysis of the heart, dilated pupil, peculiar weak faintness, and yet the clear intellect indicative of prussic acid, cause and effect were rightly understood; and by administering the antidote of prussic acid, both gentlemen were speedily restored to perfect health.

Take another case, as an example of the necessity of an accurate knowledge of chemistry, as well as anatomy and physiology, and the influence of poisonous drugs upon the general system. A person affected with paralysis of the exterior muscles of both fore-arms, supposed to have been dependent upon a disease of the spine, and for which she had been treated with a spinal brace, which she had worn for two years, and described by a recent author, as a case of "carnomania" or "insanity of the flesh," if any of any one knows what that means, came to me a short time since.

She had been treated for disease of the spine; a brace had been supplied, and she had been assured that the paralysis of the arms would be removed in two or three months, or at all events in a very short time, so soon as the disease in the spinal column had been cured. She was sent to her distant home, and for two long years has worn the spinal brace, with still increasing deficiency of the power of the fore-arms, until within the last few months; she had become perfectly paralyzed, and was helpless, unable to pin her clothes, comb her hair, or feed herself, or indeed do any thing else, than simply to close her fingers. Upon making a most careful investigation of the case, I could find nothing of disease in any part of the body that would justify this peculiar condition of the fore-arms, except the potent influence of the poisonous power of lead.

The peculiar characteristic of lead poison is, that the hands drop, and are incapable of being extended, although the power of flexion exists. We have other varieties of paralysis, attacking different limbs; but there is no other characteristic paralysis of the hand that simulates the action of the lead. I gave it as my diagnosis, that this was a case of lead palsy. The next question was to ascertain how the lead got there. It is a common thing in New York, where we drink water through leaden pipes, to see these cases. Others are poisoned by drinking champagne from bottles that have been washed with leaden shot, and the lead left in the bottle.

In this instance no lead had been obtained in that way; the mother stated that the water was brought from a spring, kept in a bucket, and drank from a gourd. I wanted to know if the house had been painted recently. No; "she had not been exposed to lead in any way." So, I was unable to ascertain any source from which lead could be obtained. I found the lady had ridden a horse which had run off with her for some distance, one or two miles, and she was disposed to attribute the loss of power to excessive muscular action. Still the peculiar characteristics of lead being so marked, I could not give up my hunt for the poison, which had been, in some way, so insidiously introduced. After two or three days of close questioning, the lady very innocently asked me "if whiting would do it." When I asked her what it was, she handed me a beautiful little bottte and said "it was this," and on looking at the label I found it was "Laird's Bloom of Youth," a cosmetic, which you will see advertised on all the curbstones, which had been used upon the face, and here was the practical result. Taking the bottle to Prof. Doremus, I received an analysis the following day, stating that it was highly charged with lead. I immediately administered to her the proper antidote for lead. And collecting some of the secretions for a number of days, gave them also to Prof. Doremus for analysis. And I am happy to state that distinguished chemist has presented to me a specimen of the lead in its metallic form, obtained from these secretions; thereby fully corroborating the accuracy of my diagnosis, and the correctness of the treatment. As the lead is being eliminated from the body, I am happy to state that muscular contractions are returning to the paralyzed limbs; and thus ends our case of "carnomania."

This case shows you the necessity of an intimate knowledge of chemistry, and the superior advantage of its appreciation, in the removal of disease, as compared to the plan of mechanical support. It might, in fact, be called a case of lead *versus* steel. The lead to paralyze, the steel to support; and as soon as the lead is removed, the steel is not required. — *Prof. Sayers.*

PEPSINE IN DIPHTHERIA.

In the December number of the Richmond and Louisville *Medical Journal*, is a most interesting communication from Prof. Doughty, of the Georgia Medical College at Augusta, Ga., describing the treatment of a case of false membrane from diphthéria with an acidulated solution of pepsine. We have only room for a synopsis of the case.

Having first tried cauterization with nitrate of silver, and a gargle of chlorate of potash, then tincture of iodine diluted, in place of the chlor. potash, then both, and finally inhalations of atomized lime-water without success, the membrane continuing to form and the general symptoms aggravated, Prof. D. abandoned them all and ordered the constant application, by means of a hair pencil and atomization, of the following wash: —

℞ Pepsine (Boudault's)	ℨj
Muriatic Acid dilute	gtts x
Water Q. S. to make	℥ iij m

The compound was filtered to separate the insoluble starch with which the pepsine is incorporated, and the Professor adds in a note, —

"Boudault's preparation of pepsine is made from the stomach of the calf; perhaps that of Bullock's, made from pigs' stomach (pepsina porci) would be best. If substituted for the above it will require not more than 15 grains, as it is said to be four or five times stronger. Again, lactic or phosphoric acid may be preferred by some; if so, only a slight excess of free acid is needed, and either of the several acids (muriatic, lactic, and phosphoric) might be used. Perhaps the lactic is the best, as recent investigations indicate that as probably the free acid found in the stomach during digestion."

In this case the patient died, but not till the false membrane had entirely disappeared, being coughed up in lumpy masses partially dissolved, death taking place apparently from constitutional depression, and not until sufficient time had elapsed to prove the success of the local measure.

Hypophosphite of Lime in Abscess. — Dr. W. S. Searle (*N. E. Med. Gazette*) has cured many cases of superficial abscesses, vulgarly called "cold boils," by a treatment of hypophosphite of lime. Dose, in very violent cases, as large as five grains every three hours. It will not do to use it in acute abscess attended by fever, at least not in so low a preparation; but in torpid, scrofulous abscess, it will, he thinks, always prove efficient.

FREE HYDROCHLORIC ACID IN THE GASTRIC JUICE.

At the meeting of the American Association for the Advancement of Science, held at Chicago on the fifth of last August, Prof. E. N. Horsford, of Cambridge, Mass., read a paper on "The Source of Free Hydrochloric Acid in the Gastric Juice." He said the long-disputed position of Prout, that the gastric juice contains free hydrochloric acid, was at length established by Schmidt, who, in an absolute quantitative analysis of the juice, found about as much hydrochloric acid as was required to neutralize all the bases present. The prolonged discussion of this subject, now since 1823, has brought to light, through the researches of Lassaigne, Tiedemann and Gmelin, Berzelius, Lehmann, Cl. Bernard, Blondlot, and numerous others, the unmistakable evidence of the presence of lactic acid and of acid phosphates in the gastric juice, which might or might not be due to the presence of lactic acid or hydrochloric acid. A point of special interest to the chemist and physiologist still remained, and was this: How could free hydrochloric acid be secreted from the blood, which is an alkaline fluid? This question was submitted to experiment with entirely satisfactory results.

The blood freshly drawn consists of a fluid (the plasma) in which there are swimming about myriads of exceedingly minute irregular spherical bodies (the corpuscles). The plasma consists of two bodies, one of which, the fibrine, spontaneously separates from the other, the serum. The corpuscles are little sacs of delicate animal membrane inclosing a fluid. This fluid has an acid reaction, and its ash contains a monobasic alkaline phosphate. The fibrine of the plasma contains a monobasic phosphate of lime, though the plasma, as a whole, has an alkaline reaction, and contains a great excess (11 per cent) of chloride of sodium (common salt.)

The moist corpuscles constitute about one half of the blood.

The relations of the fluid within the corpuscles to the plasma which surrounds them, is the same as that of the yolk to the white of the egg, and the ratio of fixed base to phosphoric acid is alike in both cases:

1 : 1 in blood corpuscles,
1 : 1 in egg yellow.

The ash of albumen contains nearly one third of its phosphoric acid as monobasic phosphate (3.79: 1.15), according to Poleck, while the same analyst gives for the analysis of the yellow 66.70 per cent of phosphoric acid, of which 41.33 per cent are free. (*Liebig's Jahrs Bericht*, 1850, p. 559.)

Under pressure, the fluid contents of the corpuscles pass through their membranous walls, and through the walls of the nutritive capillaries. Such pressure exists when the bloodvessels of a particular organ are engorged, as the bloodvessels of the stomach always are in healthy digestion. Under such pressure, the areolar tissue under the mucous membrane is charged with the mixed fluids of the corpuscles and plasma. This mixture contains, therefore, acid phosphates and chloride of sodium.

The mucous membrane of the stomach presents on its inner surface the mouths of numerous microscopic tubes, which, like a stocking, are sometimes single fluid sacs, or, like a glove, terminate in several fluid sacs, like the glove fingers. In the bottoms of the tubes and along their sides are several closed, spherical sacs, containing other lesser sacs and fluid within.

The tubes, as a whole, dip down into the spongy tissue that underlies the mucous membrane, where they are surrounded by the fluid poured from the surrounding rich work of nutritive capillaries, which fluid contains acid phosphates and chlorides.

Now by pressure and osmosis, a portion of this fluid will pass through the wall of gastric tubes, and the question is whether the fluid that goes through will contain free hydrochloric acid.

The experiments I have made are conclusive on this point.

By employing acid phosphate of lime and common salt, I had this advantage, that as increased acidity on the one hand is a just inference from increased alkalinity on the other, and as increased alkalinity would be shown by the precipitation of phosphate of lime — a visible white powder — I could determine the qualitative fact without the difficulties and delay attendant on accurate quantitative analysis of the solutions before and after the refinement, on both sides of the membrane.

With acid phosphates of lime in my earlier experiments, I was embarrassed with the presence of sulphate of lime in the powder, so that what was at first supposed to be pure phosphate of lime, was found to be in part sulphate of lime. This sulphate was due to imperfectly washed parchment paper, employed as a dialyser. This difficulty overcome, the experiments were made with parchment paper prepared from German and Swedish filter paper, as well as with goldbeater skin.

I employed acid phosphate of lime successively with chloride of sodium, with chloride of potassium, with chloride of ammonium, with chloride of calcium; with all of which there was the same kind of evidence of increased alkalinity on one side, and of course corresponding increased relative acidity. The same effect took place on the other with acid phosphate of soda and chloride of calcium. It follows, then, from what we know of the composition of the blood, its condition in the walls of the stomach, and the structure of the gastric tubules, that free or uncombined hydrochloride acid must find its way into the sacs at the bottoms of the tubules. It is of course mixed with acid phosphates and alkalin

chlorides. The sacs at the bottoms of the tubules, by a secondary dialysis, concentrated the acid solution. Swelling by endosmosis, and corroded by the acid and juice, at length they burst, and the liquid contents, together with the disintegrated and partially digested membrane of the sacs, pass out to the stomach to constitute the gastric juice — the free hydrochloric acid and the disintegrated tissue (the pepsine?) to act in the liquefaction of the food.

CARBOLIC ACID.

Editor of the Boston Journal of Chemistry: —

Your remarks, in the last number of the *Journal*, on carbolic acid and the duty of calling the special attention of physicians to this important agent, that a clear understanding of its nature and the character of its solutions may be secured, appear appropriate and important. I could wish that the terms of that, and some other articles, were better understood and used with more precision. Permit me, in the interest of the public welfare, to mention, through your *Journal*, a recent case that may illustrate, somewhat, the importance of the subject.

The writer of this note received a prescription for two ounces of "carbolic acid," without any qualification. Learning that it was to be mixed with linseed oil by the patient or by the attendant, the carbolic acid, in liquid form, was put up, in precise compliance with the prescription. It was not satisfactory to the physician, and was set aside, and a "*solution of carbolic acid*" procured. This was *the article intended* by the prescription. It contains, as stated in the *Journal*, precisely *five* per cent of pure acid, being a very different article from "carbolic acid" of about *ninety-five* per cent.

If the physician had required camphor water he would not have written for camphor, nor should he have ordered carbolic acid when he intended the aqueous solution of carbolic acid.

Certainly, in dispensing an agent of such potency as that under consideration, the apothecary should not be left to conjecture the intentions of the physician. The question of safety in the use of that article as in others, usually, is not cognizable by the apothecary, excepting, of course, obvious mistakes, should such occur, and there appears no safe or proper rule but to follow strictly the directions of a written prescription.

I have, not unfrequenetly, within a few months, dispensed carbolic acid in liquid form, as well as that in form of crystals, in obedience to the prescriptions of intelligent physicians. With the more prominent and reliable apothecaries in Boston, the usual practice is when carbolic acid is required, and when he is guided only by what appears on the face of the prescription, to furnish the article in the form of crystals.

This remedy having been so recently introduced into use, it is not surprising that its exact nature is not fully understood by all, and that its different terms should sometimes be confounded. J. L. H.

HINGHAM, Nov. 1868.

DR. LEMBKE ON COPPER. — Touissart relates, in the *Wiener Wochenschrift*, that laborers in verdigris are colored green, even to the bones, and yet enjoy good health. Second, that no combination of copper corrodes the mucous membrane of the stomach; for even nursing babies take, in croup, several grains of salts of copper without any detriment. Third, all salts of copper, with the exception of the innocuous sulphite of copper, produce only vomiting and purging. Fourth, during a longer sojourn in the body, they change to sulphite of copper and albuminate of copper, but not to acetate of copper. Fifth, it is not certain, yet, in which form they get excreted through the kidneys. Sixth, fatal cases of poisoning by copper have never been observed. Seventh, copper colic and chronic copper diseases are found in books, but not in reality. Eighth, workers in copper are, next to workers in iron, not only the most healthy laborers, but in general enjoy good health.

Still, in spite of all these remarks, manifold experience has shown that a substance may produce on the healthy only insignificant manifestations, pointing to certain diseased states, and yet be able to have great remedial power against the established and seated disease; as cuprum for cholera, nervous diseases, etc. We prefer the cuprum aceticum to the metallicum.

THE MARRIAGE AND DEATH-RATE.

It is a curious and instructive fact, that out of every 100,000 married persons (including widowers) at the age of 20, 626 die before attaining the age of 25, while out of a similar number of persons unmarried at the same age, no less than 1,231 die before attaining the age of 25. The following table, founded on the vital statistics of Scotland, shows the comparative death-rate of married and unmarried males from 20 to 85: —

Ages.	*Husbands and Widowers.*	*Unmarried.*
20 to 25	6.26	12.31
25 to 30	8.23	14.94
30 to 35	8.65	15.94
35 to 40	11.67	16.02
40 to 45	14.07	18.35
45 to 50	17.04	18.35
50 to 55	19.54	21.18
55 to 60	26.14	28.54
60 to 65	35.63	44.54
65 to 70	52.93	60.21
70 to 75	81.56	102.71
75 to 80	117.85	143.94
80 to 85	173.88	195.40

Dr. Stark, the Register-General of Scotland, infers, from these figures, that "bachelorhood is more destructive to life than the most unwholesome trades, or than residence in an unwholesome house or district, where there never has been the most distant attempt at sanitary improvement of any kind." We do not question the opinion that matrimony may, in a thousand ways, exercise a healthful influence on the human race, by ennobling its habits and enforcing sobriety, etc., but we think Dr. Stark exceeds the legitimate conclusion consequent on the premises. It must be remembered that married men are generally of a more robust and healthy constitution than bachelors, who frequently are deterred by ill-health from undertaking the support of families. This important element in the calculation has been forgotten by Dr. Stark and reasoners of his class. — *World.*

ORIGIN OF HEPATIC SUGAR.

DR. NICHOLS. — Dear Sir: I hail the monthly visit of your journal as that of a scientific friend, and never fail to find something in it of great interest. May I hope to see in the next issue of it, a solution of the following surmise, in reference to the origin of hepatic sugar — "glycogene," as it has been called. This substance is supposed by leading authorities on physiology to be similar to glucose, or the sugar of starch, and to be formed from amyloid substances in the blood or in the tissue of the liver. I am inclined to take a different view of the matter, and beg your opinion of it. In its more prominent mechanism, the liver is a bile making organ; it is moreover, *incidentally*, a syrup making organ, and the latter action I look upon as a mere result of the former, in this way. In its main constitution bile is a liquid soap, formed by a combination of a fat-acid, choleic acid, as it is called, and soda. The materials are supplied by the circulating fluid and chemically combined by the cell development of the liver. The fat is probably but the ordinary combination of stearine, magarin, and elain with glycerine; and in the formation of bile, as in ordinary soap-making, the fatty principle is released from its sweet base, becomes a fat-acid and combines with soda, forming a saponaceous solution which is poured out by the hepatic ducts, while the emancipated glycerine, or the most of it, flows out with the blood through the portal veins. The tendency to form this soap is so strong in the cell action of the liver, that even when drained of its blood, the formation of the soap goes on out of the substance of the liver itself, which contains both the fat and the soda; and of this action, the formation, or rather separation, of the sweet principle is but the natural result.

Respectfully, PHILIP HARVEY, M.D.

DR. J. G. PINKHAM, of Lynn, Mass., tells in the Boston *Medical and Surgical Journal* that he cured a case of chronic catarrh of twelve years' standing, by a simple douche of water and common salt. The douche was blood warm and the salt in the proportion of one half an ounce to two quarts of water. At first, the patient suffered from pain in the back of the head during the operation, but after a time that ceased; and after two months of daily application, all symptoms of the disease disappeared.

ADULTERATION OF CREAM TARTAR AND SODA.

DR. NICHOLS. — Dear Sir: Thinking that the *Journal* has a larger circulation among families than any other of the kind, I wish you would give some practical directions for detecting impurities in *Cream Tartar* and *Soda*, articles which many will persist in using, in spite of their known deleterious influences upon health. Inclosed I send you a sample of *Cream Tartar*, which has produced (in my own practice) seven or eight cases of serious *colitis*, followed by bloody evacuations. These cases occurred after eating pastry in which this cream tartar was used. In all of these cases the *colitis* ensued in about *six hours* after meals. Please answer through the next number of your *Journal*, and oblige, yours truly,

GEORGE D. STANTON, M.D.

STONINGTON, Conn., Dec. 5th, 1868.

NOTE. — The substance sent to us with the above proved, upon analysis, *not* to be bitartrate of potassa, or cream of tartar, but a *mixture of phosphoric acid with starch*. It is almost or quite impossible to procure through the ordinary sources of supply pure cream of tartar, or, indeed, any other of the substances or condiments used in households. If cream of tartar is adulterated with flour or starch, a drop of a weak solution of iodine instantly detects it by affording a deep-blue reaction. If it contains ground pumice-stone or rice, hot water turned upon it takes up the salt, and leaves behind the insoluble impurities. It is seldom that *poisonous* admixtures of cream of tartar are found in the market.

SALTS OF MORPHIA. — We have been engaged, for several months, in perfecting arrangements for supplying to our wide circle of medical friends and druggists, the *pure salts of morphia*, of our own brand. We can probably furnish the sulphate, acetate, muriate, etc., of morphia, of *very superior quality*, by the middle or last of the present month of January. All the alkaloidal and acid principles of opium, in their utmost purity and excellence, we shall be able to supply in any quantities desired. Our list of reliable therapeutic agents, we intend to make as extensive and complete as possible, to meet the pressing demands constantly made upon us.

J. R. N. & CO.

COD-LIVER OIL WITH HYPOPHOSPHITES OF LIME AND SODA. — The attention of physicians is called to the advertisement of this valuable combination, which will be found upon tenth page of the *Journal*. The association of pure cod-liver oil with the hypophosphite salts meets with the approval of a large number of our most distinguished medical men.

THE FUNGUS THEORY OF DISEASE. — In a short communication to the *Centralblatt*, Drs. Bergmann and Schmiedeberg describe a crystalline substance, to which they have applied the name "sulphate of sepsin," obtained from putrefying materials, and which they believe represents the proper poison of organic substances undergoing this kind of fermentation. It is obtained, says the *Lancet*, by diffusion through parchment paper, precipitation with corrosive sublimate from an alkaline solution, removal of the mercury by silver, of silver by sulphuretted hydrogen, evaporation, and purification of the residue. Large, well-defined, acicular needles are thus obtained, which are deliquescent in the air, and, exposed to heat, melt and carbonize. They possess a powerfully poisonous action. A solution containing scarcely more than one hundredth of a gramme was injected into the veins of two dogs. Vomiting was immediately induced, and after a short time, diarrhœa, which in the course of an hour became bloody. After nine hours the animals were killed, and on examination their stomachs and large intestines were found ecchymosed and the small intestine congested. Frogs could be killed in the same manner.

IRON REMEDIES.

A considerable knowledge of chemistry is requisite in order to understand how and when to prescribe and take remedies. This is especially true of the metals and their salts. Preparations into which iron enters as a constituent in any form should never be taken upon an empty stomach. Quacks have a stereotype way of directing that their bitters and decoctions should be taken "half an hour before meals." Many invalids, unless specially directed by their physicians, commence to take iron at such periods, and are greatly distressed in consequence. We have known this class of agents to be thrown aside when the patient greatly needed the remedy, because it was taken at improper times, and caused disturbance. Iron should not be taken fifteen, ten, or even five minutes before meals, but during, or immediately after. It will then be mingled with the food, and go through the process of assimilation in connection with it.

It should not be taken with any meal at which tea is used, as the tannic acid of the tea promotes decomposition, and forms in the stomach tannate of iron, which is *ink*. Physicians cannot be too careful in directing patients how and when to take the preparations of iron.

Apoplectic Tendencies.—It is a delusion, that persons of a certain configuration are prone to apoplexy. It is said that the pattern of body which is most prone to apoplexy is denoted by a large head and red face, shortness and thickness of the neck, and a short, stout, squat build. A man with a red face has no more blood in his brain than another; it is a mere idle fancy. It is the associating two things together in our imagination which have no real connection. Apoplexy is a pouring out of blood in the brain from a ruptured vessel. The person in whom the vessels are diseased is the one in whom apoplexy is most likely to occur. Such a person is often pale and thin, with a long neck.—Dr. Samuel Wilks, *in the Medical Times and Gazette.*

Danger Arising from the Exhalations of some kinds of Fruit.—It is a well known fact that the perfume of some kinds of flowers is injurious to health, and even causes death, if flowers are kept in a confined space frequented by men at the same time. One of the local papers of the city of Lyons now records the fact of death by asphyxia, suffered by a lady who slept in a room wherein a large quantity of quinces were kept. According to scientific evidence, given in this instance, the air of the room was largely vitiated with a peculiarly suffocating perfume, and a very considerable amount of both carbonic acid and carbonic oxide gas. The room in question was always used as a bed-room; no fire had been lighted in it, nor was any other discernible cause for the death of this lady found but the exhalations of the fruit.

Microscopic Germs in the Air.—An interesting experiment was recently tried at the Manchester (Eng.) Royal Infirmary. An ounce of distilled water in a pint bottle was thoroughly ærated with the atmosphere of one of the wards, until, from being transparent, it had become slightly opalescent. In the deposit thus thrown down, after forty-eight hours, distinct evidences of the presence of organic life were perceptible under the microscope; and on the fifth day there were numerous actively moving vorticelli, with abundance of monads in ceaseless motion. From this it may be inferred, if the same experiments were repeated under varying circumstances, it might be shown that the presence in the air of microscopic organic germs is a constant condition easily detectable.

Sulphate of Nickel in Neuralgia.—Palmer, in *The Medical Record*, No. 56, Vol. 3, 1868, reports a cure with this remedy. The disease had resisted treatment for three years, and during the last two months had become very severe. Half grain doses were given thrice daily, and in eight days the paroxysms were reduced to one in twenty-four hours. With this amelioration of the disease, the pulse diminished in frequency, and sound sleep was procured. The medicine was then continued until a perfect cure was effected.

ADULTERATION OF MEDICINES.

"There is no species of fraud so universal as that which, prompted by a sordid desire after filthy lucre, cheats mankind out of life and health."

Such was the expression of a writer who, more than a score and a half of years ago, published "Notes on Falsifications and Adulterations," hoping thus to prevent the sale of imprue drugs and medicaments.

Any one examining the present condition of the drug market, will readily come to the conclusion, that the attempts to falsify and adulterate have since then rather increased; for it has become almost as difficult to procure reliable medicines as it is impossible to discover the philosopher's stone. Under these circumstances, it is a duty to expose such frauds, in order to enable those who are interested to protect themselves against them. With this view, I propose to publish, from time to time, in these columns, such adulterations as have come to my notice in the Chicago drug-market. I am convinced the honest druggist, who strives to offer nothing but reliable goods to the public, and the physician who naturally expects certain results from rationally prescribed medicines, will assist me in my efforts.

Epsom Salts.—There is a large quantity of a spurious article in the market, which is nothing more than finely crystallized glauber salt. It does not contain a trace of sulphate of magnesia. It may be recognized by the circumstance that it is perfectly free from bitterness to the taste, and that its aqueous solution produces no precipitate on adding first phosphate of soda and afterwards aqua ammoniæ.

Sal Rochelle.—An article purporting to be sal rochelle is now offered for sale, which contains at least 25 per cent of sulphate of soda. This can be discovered by adding to a somewhat dilute solution of the suspicious salt a few drops of a solution of either nitrate of baryta or chloride of barium, and afterward c. p. nitric acid. The precipitate produced by the baryta salt must disappear on the admixture of the nitric acid if the salt is pure.

Vienna Glycerine.—I had occasion to examine this really beautiful-looking article, and found it contaminated with sulphate of lime (gypsum) and chloride of sodium (salt). It contained also considerable quantities of sugar.

The presence of the sulphuric acid of the gypsum can easily be made manifest, by adding to one sample a few drops of a baryta salt solution, and afterwards diluted nitric acid; that of the lime, by admixing to another sample a solution of oxalate of ammonia. The chlorine of the salt is discovered by the appearance of a white precipitate on the addition of nitrate of silver solution.

It is a little more difficult to demonstrate the fradulent admixture of sugar. In order to do so, it is necessary to add about fifteen or twenty drops of diluted sulphuric acid to two or three drachms of the glycerine, previously diluted with its own bulk of water. This mixture is boiled over the spirit lamp for several minutes, when it is allowed to cool down. It is then mixed with a few drops of a solution of sulphate of copper, and as much caustic potassa (liquor potassa) as is neccessary to redissolve the blue precipitate which at first made its appearance. The whole is then gently heated over the spirit lamp, when a copious brick-red deposit of suboxide of copper is thrown down. Pure glycerine will, under such treatment, not produce these phenomena.

Black Sulphuret of Antimony.—A quantity of powdered black sulphuret of antimony, purchased from one of our wholesale houses, was boiled with hydrochloric acid, in order to prepare the officinal "solutio antimonii terchloridi" (butter of antimony). It was but incompletely acted on, and the solution, after cooling, was filled with numerous crystals, which on examination were recognized as chloride of lead. A portion of the black residue not taken up by the hydrochloric acid was also examined; it consisted mainly of sulphuret of lead (galena).—F. Mahla, Ph. D.: *The Pharmacist* (*Chicago*).

SUICIDE BY CHARCOAL.

A contemporary mentions that a Paris periodical states that "suicide by charcoal fires in a close room [would it be possible in an open room ?] is purely a literary invention, first used by M. Crosnier, in a drama produced in 1825;" adding, "Since then, it has been the fashion for working-girls bent on self-destruction to accomplish their end in this way." This statement is ridiculous, suicide by charcoal fires being one of the "sad sentences of an ancient date" passed by unfortunates on themselves before the beginning of the Christian era; and it was one of the many modes of self-destruction resorted to by classic ladies and gentlemen who left the world "after the high Roman fashion." The story that Porcia, daughter of Cato and wife of Brutus, filled her mouth with coals from a burning brazier, and so died, after the defeat and death of her husband at Philippi, means that she inhaled the fumes of charcoal. This was more than nineteen hundred years ago; and, more than forty years earlier, Quintus Lutatius Catulus, one of the victims of Marius, committed suicide "by swallowing fire" (*ignis haustu*), according to Florus; but Velleius Paterculus says that he "shut himself up in a place lately plastered with mortar, had fire brought in to raise a strong smell, and then, by inhaling the noxious vapor, and holding in his breath, he found a death agreeable to his wishes," etc. No one could swallow fire; and the statements that Catulus and Porcia did so are as absurd as the story that Cranmer stood up and coolly put his "wicked hand" in the flames till it was burned before his body was consumed,—a proceeding utterly impossible in any man, and not to be thought of in the case of so weak-nerved a man as Cranmer was throughout life, and which, had it been possible in him, his enemies would not have allowed him to do; for the offence of which the archbishop's hand had been guilty was committed at their persuasion. In modern times, deaths by inhaling the fumes of charcoal, as well accidentally as purposely, occurred long before 1825; and, as this form of death is painless, it is a favorite with self-killers. That women resolved on dying should prefer it, is natural; for the sex have strong ideas on decorum, even in death; and thus to die, leaves the features undistorted, and the body as if the suicide were in the enjoyment of a profound and dreamless sleep,—as, in one sense, it is. Persons who have been accidentally smothered by the fumes of charcoal, and then resuscitated, say that they had no more recollection of what happened to them than men have of the process of falling asleep.

Vaccine Virus from Kine.—Arrangements have been completed by which we are able to furnish physicians pure vaccine matter from kine. The heifers from which the crusts are obtained belong to herds owned in the country, and none are vaccinated not perfectly sound and healthy. The crusts are secured while fresh, and inclosed in hermetically sealed packages, and will reach the physician in perfect condition. Price of a whole crust $3.00; half a crust $2.00. We can also supply vaccine matter from perfectly healthy children. Price of whole crust $2.00; half do. $1.50.

Physicians, by inclosing to us the money for a whole or half crust, will receive the virus by return mail; and the utmost reliance may be placed upon the statement that it is procured from the purest sources.

Two more beautiful frescoes have been found at Pompeii, supposed to be portraits of the master and mistress of the house in which they were discovered. The woman is represented as seated, and preparing to write. The frescoes have been sent to the museum at Naples.

Hippophagy has not met with success in Paris. The government was willing; the *savans* urged the people to eat and set the example; the storekeepers added horse-flesh to their stock; but customers were lacking, and there are indications that the movement will be abandoned.

Nitrate of Amyle in Nervous Pains.—Inhalation of the vapor of nitrate of amyle has been known to cure some of the worst of nervous pains, such as tic-douloureux, sciatica, etc.

Blood Soups.—A writer in the *Medical Times and Gazette*, strongly recommends blood soups as far more nutritious and supporting than those made from the ordinary extracts, in cases of exhaustion from typhoid fever and other prostrating diseases.

At a meeting of the London Medical Society, Dr. Blake, a distinguished practitioner, said that he was able to cure the most desperate case of toothache, unless the disease was connected with rheumatism, by the application of the following remedy:—Alum, reduced to an impalpable powder, two drachms; nitrous spirits of ether, seven drachms; mix, and apply to the tooth.

Directions for Using Cod-Liver Oil.—Dr. C. J. B. Williams, a high authority on phthisis, says that the best time for the administration of the oil is immediately after, or, to those who prefer it, at or before a solid meal, with which the oil becomes intimately blended, and is less likely to rise by eructation than when taken upon an empty stomach. The dose of oil should rarely exceed a tablespoonful twice or thrice daily; when a larger amount is taken at a time, it generally either deranges the stomach or liver, or some of it passes unabsorbed by the bowels. In conclusion, Dr. W. says that, in many cases of consumption, life may be prolonged for many years in comfort and usefulness; and in not very few cases, the disease is so permanently arrested that it may be called cured.

Effects of Tobacco Smoking on Children.—The usage of smoking tobacco by children causes paleness, loss of flesh, palpitation of the heart, derangement of the digestion, and all the symptoms of impoverished blood. No treatment is effectual as long as the habit is continued. The intelligence is diminished, and a tendency to strong drink excited. These symptoms disappear, where there is no organic lesion, with the discontinuance of the habit. In twenty-seven out of thirty-eight cases observed in children between nine and fifteen, some or all of these symptoms were observed.—Dr. E. Ducaisne: *Gazette des Hôpitaux.*

Cough Mixture in Chronic Bronchitis.—Flint.

℞ Linseed oil........................ 1 oz.
Simple syrup........................ 1 oz.
Fl. peppermint........................ 2 to 4 drops.

M. Two teaspoonfuls three times a day.

Carbolic Acid Collyria.—Dr. Markey, in the *Lancet*, recommends the following formula in purulent ophthalmia:—

℞ Carbolic acid........................ 1 drop.
Glycerine........................ 5 drops.
Rose-water........................ 1 oz.
M.

Dr. Gadberry's celebrated tonic is prepared according to the following formula:—

℞ Pulv. sulph. of iron........................ ʒj.
Nitric acid........................ f. ʒj.
Sulph. of quinine........................ ʒij.
Citrate of potash........................ ℈ij.
Cinnamon water........................ f. ℥viij.

M. Put the acid and iron together, add the quinine gradually, and then, having previously dissolved the potash in water, mix all well together.

S. A teaspoonful every four hours.

Dr. McGugins's treatment for epilepsy is worthy of reproduction:—

℞ Hydrocyanate of iron........................ ʒj.
Powdered valerian........................ ℥ij.
Extract of Indian hemp........................ ʒj.

M. 120 pills.

S. One pill three times daily, gradually increasing to four.

Dr. Weigenheim, of Berlin, gives the following formula for administering ipecac:—

℞ Pulv. ipecac root........................ gr. iij.
White sugar........................ ʒij.

M. Twelve powders.

S. One powder every five minutes until vomiting is produced.

Dr. Bemiss recommends the following in acute alcoholism:—

℞ Bromide of potash........................ ʒss.
Tinct. of lupulin or hydrociamus........................ f. ʒj.
Water........................ f. ℥j.

M. S. The whole at one dose.

OF

CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. III.—No. 8.] BOSTON, FEBRUARY 1, 1869. [ISSUED MONTHLY, AT FIFTY CENTS PER ANNUM.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.

RECEIPTS.—No receipts for subscription moneys will be given unless paid at the office. The arrival of the *Journal* will be evidence that subscriptions are received.

A list of premiums is offered to those who obtain subscribers.

Contents.

Familiar Science.

MOUNT VESUVIUS.

A very general waking up of the slumbering volcanic forces of our planet characterized the year 1868, and rendered it remarkable for mutterings and thunderings, and overflow of lavas at all the great volcanic centres. Mother Earth, we suppose, must have her gripes and colics at certain periods, and the points of discharge or relief at such times, afford scenes of grandeur and sublimity, as well as of terror, which have no parallel in any of the operations of nature. Vesuvius and Ætna have been greatly agitated. We happened to visit Vesuvius shortly after the great eruption of May, 1855, and a danger was experienced not soon forgotten. During this eruption a new crater was formed upon the side of the mountain, towards Monte Sommo, at a point some two hundred feet below the great central abyss of fire. From this orifice an immense mass of molten lava flowed out, and running down the side of the mountain reached its base, and spread itself out upon the beautiful campagna, burning and destroying every living thing, over an area many miles in extent. At the time of our visit, the lava was still glowing and smoking in its rocky bed a mile from the point of its emission. A solid crust, resembling ice formed upon water, and from which the liquid had been drained away, was observable for a long distance. Over this crust we were compelled to pass several times, and through orifices, the fiery liquid was seen reposing below. Cooled lava is a very imperfect conductor of heat, and when a mass has cooled or solidified upon its surface, the interior may remain liquid for many months. The scene of utter desolation, the burning, fusing, calcining effects observable in the region of a volcanic vent recently excited, is almost painful to the eye and depressing to the mind. A horrible blackness of darkness overshadows every thing, and the visitor is in a sea of cinders, dust, lava, pumice-stone, and sulphur. A most welcome relief are the green fields, and orange groves, which are passed on the return to Naples from Vesuvius.

In ascending to the edge of the great crater, we turned aside to examine the smaller one opened a few months before. It was in a state of comparative quiet, and it was possible to climb up the ragged lava formed rim, and look directly down into the horrible cavity. It resembled a huge chimney, connected with a smelting furnace, and from it there was issuing smoke and suffocating gases. A detached mass of solid lava rested upon the edge; this was toppled over, and went thundering down into the bowels of the mountain. Out of this orifice, not more than ten feet in diameter, the great river of lava had flowed, which caused so much damage. The great crater or vent was still considerably agitated, and explosions were occurring which caused the cone to tremble to its base. Large stones, or fused masses of lava, were thrown high in the air, and in the curves described they fell far up towards the outer edge of the crater. It was evidently unsafe to venture far while this unusual agitation continued; nevertheless, our guide was prevailed upon to attempt to take us around to the opposite side of the crater, that a better opportunity might be had for observation. In this attempt we narrowly escaped death, from causes similar to those which caused the death of Pliny the elder, in A.D. 79, at the time of the great eruption which destroyed Herculaneum and Pompeii. Not more than a third of the distance had been gone over, when, by a sudden change of wind, the vast column of smoke, gases, and cinders settled down upon us, and we were instantly plunged in midnight darkness. The vapors were charged with the most dreadful gases; sulphurous, sulphydric, carbonic acids, and carbonic oxide, and there was danger of instant asphyxia. Placing handkerchiefs over our mouths, we lay down upon the cinders, hoping the cloud would lift and free us from its embrace of death. Fortunately in a space of time which seemed an age, but which was probably not more than a single minute, it rose, the light came; gasping and faint we managed to drag ourselves to a point of safety. Nausea and vomiting followed, but no permanent injury was sustained. During the time we were immersed in the cloud, the acid gases, acting upon a silk hat, changed it to a bright red color, and some portions of the clothing were similarly changed. This experience may serve as a caution to those disposed to be too venturesome, in exploring volcanoes, at a time of unusual agitation.

THE NEBULAR HYPOTHESIS.

Everybody has heard of the Nebular Hypothesis of Laplace, the great French astronomer; but we presume that the great majority of non-scientific people have a very vague notion of the famous theory. We will endeavor briefly to sketch its main features, and to show its connection with some of the facts and theories which we have given in our little series of articles upon the nature, origin, and conservation of force.

According to Laplace, the material of our solar system was once a nebulous mass, of extreme tenuity; and the sun, moon, and planets were formed by its gradual condensation. Let us suppose such a nebulous mass slowly rotating, and gradually cooling by radiating its heat into surrounding space. As it cools, it must begin to contract; and as it contracts, it must rotate more rapidly, since the matter at the surface must be moving faster than that which is nearer the centre, just as the rim of a wheel moves faster than the hub. It will thus go on contracting, and rotating with increasing velocity, the centrifugal tendency becomes so great that and gravity can no longer hold it together. W hardly refer to the familiar illustration of this tendency which we have in turning a commo stone faster and faster, until the water can

adhere to its surface, but flies off in all directions. In the case of our whirling nebulous mass, a ring of matter would be detached from the circumference, and would continue to rotate by itself. The central mass still goes on shrinking, and turning with ever-increasing speed, until it throws off a second ring; and thus ring after ring is detached, and all these rings continue to rotate round the central mass, in the same direction. But the rings themselves would keep on condensing, and, at last, they would be likely to break up, each forming one or several globular masses; for into this form the matter of the fragments of the ring would, by a simple law of attraction, gather itself. These globular masses would, of course, all revolve about the central mass, in the same direction, and their condensation would cause them to rotate on their axes; and it has been proved that (with the exception of one or two of the outer ones) they must all turn on their axes in the same direction in which they revolve in their orbits.

But, as these masses condensed, their rotation would be accelerated, and they would be very likely to throw off rings, which would either remain as rings, or break up and gather into secondary masses revolving about their primaries.

The central mass, of course, forms the sun; the rings which it throws off become the planets; and the rings whirled off from the planets constitute their moons. In the case of Saturn, a part of the rings remain uncondensed, while a part appear as his eight moons.

The rings thrown off by the central mass are usually condensed into one body; but, in the case of the *minor planets*, or *asteroids*, we see a ring broken up into many bodies; and the same is true of the meteoric rings which are the source of meteoric showers.

It will be seen that all the great facts in the astronomy of the solar system are explained by this theory. The sun turns on his axis from west to east, and all the planets revolve about him and turn on their axes in the same direction. Most of these planets have one or more moons revolving about them; and these moons, with the exception of those of the two most distant planets, have both axial and orbital motions from west to east. The rings of Saturn, which have a rotation independent of that of the planet, but in the same direction, are no anomaly, according to this hypothesis; and the recent discovery (now demonstrated, we believe, to the satisfaction of all the most eminent astronomers) that the rings are steadily shrinking and approaching the body of the planet, is only a further confirmation of the theory. The ring of minor planets, of which at least one hundred and six have already been discovered between the orbits of Mars and Jupiter, is far more naturally explained by this hypothesis than by the well-known theory of Olbers, that they are the fragments of a large planet shattered by some tremendous internal explosion, or by collision with some heavenly body that crossed its track. The phenomena of meteors, also, as we have intimated, are thoroughly consistent with this view of the origin of all the bodies in our system. We need not wonder, then, that the nebular hypothesis is now accepted by the great majority of scientific men, as by far the most satisfactory theory that has ever been devised to account for the great facts of astronomy.

The nebular hypothesis explains also the internal heat [illegible] the earth and the heat of the sun; for, as the particles [illegible] nebulous mass were drawn nearer and nearer [illegible]r, their "possible energy"* must have been con[illegible] into heat. The celebrated Helmholtz has made this the basis of his theory of solar heat, which is not inconsistent with that of Mayer, described in the November *Journal*. Helmholtz assumes, with Laplace, that the nebulous matter was of almost inconceivable tenuity, and determines by calculation the heat which would be generated by its condensation to the present solar system. Supposing the *specific heat* of the condensing mass (that is, the heat which it would take to raise the temperature of one pound of it one degree) to be the same as that of water, he finds that the heat of condensation would be sufficient to raise the temperature of the mass, or the masses formed from it, more than 50,000,000 degrees Fahrenheit.

Some one may fancy that there is an inconsistency in this supposition that the cooling and contracting of the nebulous mass can generate this intense heat, and that the mass nevertheless goes on contracting. But it must be borne in mind that the heat is continually radiated off into space; and it can, moreover, be proved that, as the particles come nearer together, the force of gravity, which tends to draw them towards the centre, increases more rapidly than the repulsive force of the remaining heat, which tends to drive them *from* the centre.

Of course, we can have no conception of a temperature of fifty millions of degrees. The most intense heat which we can produce by any means at our command, is only about 3,600 degrees. How is it possible for us to conceive of a temperature thirteen thousand times greater than that at which iron and other metals are dissipated into vapor? If the whole solar system were composed of pure coal, and were burned up, the heat given out by the great conflagration would amount to only 1-3500th of that produced by the condensation of nebulous matter by which that system was formed. Helmholtz supposes that this condensation is still going on, and that this continued shrinking of the sun causes a continued development of heat within his mass. He shows, by calculation, that a shrinkage amounting to 1-10000th of the sun's diameter would generate as much heat as the sun radiates in two thousand years; and that a contraction of the sun's mass from its present density (which is about one quarter that of the earth) to the density of the earth, would develop an amount of heat equal to the solar emission for seventeen million years.

We have said that Mayer's theory of solar heat is not inconsistent with that of Helmholtz. It is rather supplementary to it; since it merely assumes that the meteors and planets which were thrown off from the nebulous mass, as it condensed, are slowly falling into it again. When these shall all have fallen back, and the condensation shall have ceased, our sun will cease to shine, like many other stars which have disappeared from the heavens.

* [illegible] article entitled "What is Force?" in the *Journal* for [illegible]

HOW THE ANCIENTS DINED.

Dr. Letheby, the celebrated writer upon dietetics, has been giving a course of lectures upon food, etc., in London, which, in many respects, are very interesting. We give below a few extracts from one of the lectures, showing how the old Romans and also how the more "modern ancients" dined: —

Among civilized nations, and until comparatively recent times, there were but two meals a day; viz., dinner and supper. These were the meals of the Romans; the prandium or dinner being for the most part a light refreshment, eaten while standing, at about nine o'clock in the morning, and it generally consisted of the cold remains of yesterday's supper. It was commonly taken without wine; and, in fact, there was so litle ceremony about it, that Plautus, in his comedies, has facetiously called it *caninum prandium*. The great meal of the day was the supper, or *cœna*, which was taken about three or four o'clock in the afternoon, and to which friends were invited. This was the ceremonious meal for which the wealthy and high families of Rome exhausted the resources of luxury and art. It always consisted of three parts — the *gustus* or antipast, which was intended as a mere smack or relish to whet the appetite. Then came the main part of the feast; consisting of many courses, with a chief dish, or *caput cœnæ*, and when in thrifty families it was the only dish which went the round of the frugal board, it was aptly termed the *cœna ambulans*. After this there came the second course, or *mensa secunda*, composed of fruits and pastry, like a modern dessert.

The sums of money expended by the wealthy Romans on this meal were often ruinous. Vitellius is said to have spent as much as 400 *sestertia* (about £3228 of our money) on his daily supper; and the celebrated feast to which he invited his brother Lucius cost no less than 5000 *sestertia*, or £40,350 sterling. It consisted, according to Suetonius, of 2000 different dishes of fish and 7000 of fowls, with other equally numerous meats. His daily food, says our classical writer, was of the most rare and exquisite nature; the deserts of Libya, the shores of Spain, the waters of the Carpathian Sea, and even the coasts and forests of Britain, were diligently searched for dainties to supply his table; and had he reigned long he would, says Josephus, have exhausted the great opulence of the Roman Empire. Ælius Verus, another of those worthies, was hardly less profuse in the extravagance of his suppers; for it is said that a single entertainment, to which only about a dozen guests were invited, cost above 6,000,000 sesterces (6000 *sestertia*, or nearly £48,500); and we are told by historians that his whole life was wasted in eating and drinking; being spent in the voluptuous retreats of Daphne, or else at the luxurious banquets of Antioch. So profuse, indeed, was the extravagance of those times, that to entertain an emperor at a feast was to encounter almost certain financial ruin — one dish alone at the table of Heliogabalus has been known to cost about £4000 of our money; no wonder, therefore, that these imperial feasts were lengthened out for hours together, and that every artifice, often revolting in the extreme, was used to prolong the pleasure of eating, or that Philoxenus should have wished that he had the throat of a crane with a delicate palate all the way down.

Hardly less extravagant were the dining propensities of our own forefathers, who in every way copied too closely the luxurious habits of their Roman conquerors. In fact, no circumstance, as Mr. Wright observes, is more remarkable in ancient history than the readiness with which the people who came under the sway and influence of Rome, abandoned their nationality, and followed the luxurious habits of their rulers. Even so late as the time of Holinshed, the famous chronicler of the sixteenth century, the manners of the English were the subject of severe comment; for he tells us that "in number of dishes and changes of meat, the nobility of England (whose cooks are for the most part musical-headed Frenchmen and foreigners) do most exceed; sith there is no day in manner that passeth over their heads, wherein they have not only beef, mutton, veal, lamb, kid, pork, cony, capon, pig, or so many of them as the season yieldeth, but also some portion of the red and fallow deer, beside great variety of fish and wild fowl, and thereto sundry other delicates, wherein the sweet hand of the seafaring Portingale is not wanting, so that for a man to dine with one of them, and to taste of every dish that standeth before him, is rather to yield unto a conspiracy with a great deal of meat for the speedy suppression of natural health, than the use of a necessary meal to satisfy himself with a competent repast to sustain his body withal." He adds, too, "that gentlemen and merchants keep much about the same rate; and when they make their ordinary or voluntary feasts, it is a world to see what great provision is made of all manner of delicate meats from every quarter of the country, wherein, beside that, they are often comparable herein to the nobility of the land; so that they will seldom regard any thing that the butcher usually killeth, but reject the same as not worthy to come in place. In such cases, also, geliffes of all colours, mixed with a variety in the representation of sundry flowers, herbs, trees, forms of beasts, fish, fowls, and fruits; and thereunto march-pane, wrought with no small curiosity, tarts of divers hues and sundry denominations; conserves of old fruits, foreign and homebread; suckets, codiniacs,

marmalades, sugarbread, gingerbread, florentines, wildfowl, venison of all sorts, and sundry outlandish confections, altogether seasoned with sugar, besides infinite devices, not possible for me to remember."

The learned Caius, also, in his "Counseill against the Sweat" of the same century (1552), comments in severe terms on the gluttony of his time, saying that the reason why the disease attacks the English more than others is, that they have "so moche sweating stuffe, so many euille humoures laid up in store, fro this displeasante, feareful, and pestilent disease, cause of their euille diet, whiche destroy more meates and drynckes withoute al ordre, conveniet time, reason, or necessite, the either Scotlande, or al other countries under the sunne."

Gradually, too, as the dinner got to be later in the day, and reached noontime, there was necessity for a light early meal, or *breakfaste*, as it was called; and as the dinner became later and later still, a fourth meal was added — the lunch or luncheon, which literally meant a slice of bread. In process of time, also, with the introduction of tea and coffee into England, there came a fifth meal; but all along the dinner was the great feast of the day; and the rule in using it, was pretty much as Dr. Kitchener, in his time, advised; viz., to eat until there was a sense of satiety, the stimulus of every fresh dish being but as a whip to the appetite, so that the sense of satiety might come and go a dozen times. "It is produced in us," says Christopher North, "by three platefuls of hotch-potch, and to the eyes of an ordinary observer our dinner would seem to be at an end; but no — strictly speaking, it just going to begin. About an hour ago did we, standing on the very beautiful bridge of Perth, see that identical salmon, with his back fin just visible above the translucent tide, arrowing up the Tay, bold as a bridegroom, and nothing doubting that he should spend his honeymoon among the gravel-beds of Kinnaird or Moulenearn, or the rocky sofas of the Tummel, or the green marble couches of the Tilt. What has now become of the sense of satiety? John — the castors! — mustard vinegar — cayenne — catsup — peas and potatoes, with a very little butter — the biscuit called "rusk" — and the memory of the hotch-potch is as that of Babylon the great." Sense of satiety, indeed! — "We have seen it for a moment existing on the disappearance of the hotch-potch; dying on the appearance of the Tay salmon; once more noticeable as the last plate of the noble fish melted away; extinguished suddenly by the vision of the venison; again felt for an instant, and but for an instant, for a brace and a half of as fine grouse as ever expanded their voluptuous bosoms to be devoured by hungry love."

We smile at the accounts given of the gormandizing powers of the natives of Arctic regions and the savages of Southern Africa, but our own habits in eating and drinking are scarcely less preposterous. Look at a modern dinner; beginning with soup, and perhaps a glass of cold punch; to be followed by a piece of turbot or a slice of salmon with lobster-sauce; and while the *caput cœnæ*, the venison or South down, is getting ready, we toy with an oyster paté or a bit of sweet-bread, and mellow it with a bumper of Madeira. No sooner is the venison or mutton disposed of, with its never-failing accompaniments of jelly and vegetables, than we set the whole of it in a ferment with champagne, and drown it with hock or sauterne. These are quickly followed by the wing and breast of a partridge, or a bit of pheasant or wild duck; and when the stomach is all on fire with excitement, we cool it for an instant with a piece of iced pudding, and then immediately lash it into a fever with undiluted alcohol, in the form of cognac or a strong liqueur; after which there comes a spoonful or so of jelly as an emollient, a morsel of ripe stilton or *pate de foie-gras* as a digestant, a piquante salad to whet the appetite for wine, and a glass of old port to persuade the stomach, if it can, into quietness. All these are more leisurely succeeded by the *mensa secunda*, or dessert, with its ices, its preserves, its bakemeats, its fruits, its geliffes, codiniacs, and suckets, as Holinshed would call them, and its strong drinks; to be afterwards muddled with coffee, and complicated into a rare mixture with tea, floating with the richest of cream.

On the 29th of March, 1868, a bronze cooking-pot, filled with water, was found at Pompeii. Vessel and contents were eighteen centuries old.

HANDBOOK OF CHEMISTRY FOR SCHOOL AND HOME USE.

This is the title of a little manual of chemistry, by Messrs. W. J. Rolfe and J. A. Gillet of the Cambridge High School, which is just published by Woolworth, Ainsworth & Co., of Boston. We make a few extracts from its pages, to illustrate the pleasant, familiar style in which it is written: —

RUSTING.

The slow combustion of metals is called *rusting*, and the oxide formed is called *rust*. All the familiar metals, except silver, gold, and platinum, are tarnished on exposure to the air; that is, they become covered with a film of rust, or oxide.

That *heat* is developed by rusting, as by other kinds of slow combustion, is shown by the fact that if a large pile of iron-filings be moistened and exposed to the action of the air so that they rust rapidly, the temperature rises perceptibly.

A remarkable case of heat developed by rusting occurred in England during the manufacture of a submarine electric cable. The copper wire of the cable was covered with gutta-percha, tar, and hemp, and the whole inclosed in a casing of iron wire. The cable, as it was finished, was coiled in tanks filled with water; these tanks leaked, and the water was therefore drawn off, leaving about 163 nautical miles of cable coiled in a mass 30 feet in diameter (with a space in the centre 6 feet in diameter) and 8 feet high. It rusted so rapidly that the temperature in the centre of the coil rose in four days from 66° to 79°, though the temperature of the air did not rise above 66° during the period, and was as low as 59° part of the time. The mass would have become even hotter had it not been cooled by pouring on water.

THE FOOD OF PLANTS.

Plants get their food from the earth and the air, but much the greater part from the air. We know that there are plants which flourish in the most barren soil, or even upon the naked rock, and that some live and grow suspended in the air, and having no contact with the earth. Even those which demand a rich soil are indirectly indebted to the air for what they draw from the earth. The soil owes its fertility to the decomposition of organic matter; and this organic matter was originally produced by plants which had no rich soil to draw from, but were dependent mainly upon the air.

The atmosphere, then, is the storehouse from which plants directly or indirectly obtain nearly all their food. The portion which is purely of earthy origin is always insignificant, and often it is nothing at all. In fact, plants give to the earth far more than they get from it. This is illustrated by the accumulation of vegetable organic matter in the soil wherever vegetation is undisturbed from year to year. In uncultivated fields and in primeval forests we often find a great depth of rich mould. The more rank and luxuriant the vegetation, the more rapidly this deposit increases, showing that the plants not only restore to the soil all that they have drawn from it, but are continually transferring fresh matter from the aerial storehouses to the earth.

But while the soil is enriched by undisturbed vegetation, it is impoverished by agriculture. The farmer carries away the crop from the field, with all that it has taken from both the earth and the air. The land cannot yield in this way year after year, unless he follows the example of nature, and restores to the soil an equivalent for what he removes. This he can do by the use of *manure*.

THE EARTHY PORTION OF THE PLANT.

If we burn wood or any other vegetable substance, almost all of it is dissipated into air. But a little ashes will remain; and these represent the earthy or *inorganic* portion of the plant. They consist mainly of alkaline chlorides, potash, soda, silica, metallic phosphates, calcic and magnesic carbonates, and ferric and maganic oxides. These are dissolved in the water which soaks through the soil and which is taken up by the roots of the plant. Much of the water is evaporated through the leaves, but the substances which it held in solution remain behind, and thus gradually accumulate in the tissues of the plant.

Since the plant must obtain from the soil the inorganic materials it needs, it is evident that it will flourish only in a soil containing those materials. This explains why certain plants thrive only in certain situations. A locality may be fertile for some species of vegetation and barren for others. The pines, which need little alkaline matter, will flourish in a sandy soil containing little alkali; but the maples and elms, which require a good deal of potash, cannot live in such a soil.

We have said that the farmer, who carries away the produce of the field with all that it has drawn from the soil, must restore in the form of manure an equivalent for what he removes, or the field will soon become impoverished. . . . .

This renewal of fertility is sometimes attained by letting the field lie *fallow*, or uncultivated, for one or more years. The inorganic materials of the soil are mainly furnished by the gradual disintegration of the *rocks*; and while the field lies fallow this process is going on, under the influence of the oxygen and carbonic acid of the air, aided by the rains and changes of temperature. In this way, fresh portions of the rocks or of their ruins are rendered soluble and thus fitted for the nourishment of plants.

An *alternation of crops* may answer the same purpose as letting the field lie fallow. For instance, wheat and potatoes may be raised on the ground in alternate years. The wheat requires a large amount of silica and alkaline matter, while the potatoes take up no silica. The renewal of the soluble silica in the soil therefore goes on while the potatoes are growing, as it would if the field were fallow.

Some soils abound in silicates so readily decomposed, that in every one or two years a sufficient supply for a crop of wheat becomes soluble. In Hungary there are large districts where wheat and tobacco have been raised alternately upon the same soil for centuries, the land never receiving back any of the mineral matter which is carried away with the crops. On the other hand, there are fields in which the amount of soluble silica required for a single crop of wheat is not separated from the insoluble masses in the soil in less than three or four years.

Arts.

HELMHOLTZ ON SOLAR HEAT.

We have elsewhere given a sketch of Helmholtz's theory of solar heat. The following remarks upon some of the relations of the theory to the past and future history of our globe, are translated from this eminent German philosopher, and will doubtless be of interest to our readers: —

"Though the store of heat in our planetary system is so immense that it has not been sensibly diminished by the incessant emission which has gone on during the period of man's history, and though the time which must elapse before a sensible change in the condition of our planetary system can occur is totally beyond our comprehension, the inexorable laws of mechanics show that this store, which can only suffer loss and not gain, must finally be exhausted. Shall we terrify ourselves by this thought? We are in the habit of measuring the greatness of the universe, and the wisdom displayed in it, by the duration and the profit which it promises to our own race; but the past history of the earth shows the insignificance of the interval during which man has had his dwelling here. What the museums of Europe show us of the remains of Egypt and Assyria we gaze upon with silent wonder, in despair of being able to carry back our thoughts to a period so remote. Still, the human race must have existed and multiplied for ages before the Pyramids could have been erected. We estimate the duration of human history at 6,000 years; but, vast as this time may appear to us, what is it in comparison with the period during which the earth bore successive series of rank plants and mighty animals, but no men? — periods during which, in our own neighborhood (Konigsberg), the amber-tree bloomed, and dropped its costly gum on the earth and in the sea; when in Europe and North America groves of tropical palms flourished, in which gigantic lizards, and, after them, elephants, whose mighty remains are still buried in the earth, found a

home. Different geologists, proceeding from different premises, have sought to estimate the length of the above period, and they set it down from one to nine millions of years. The time during which the earth has generated organic beings, again, is small compared with the ages during which the world was a mass of molten rocks. The experiments of Bischof upon basalt show that our globe would require 350 millions of years to cool down from 2000° to 200° Centigrade [or from 3600° to 360° Fahrenheit]. And with regard to the period during which the first nebulous masses condensed, to form our planetary system, conjecture must entirely cease. The history of man, therefore, is but a minute ripple in the infinite ocean of time. For a much longer period than that during which he has already occupied this world, the existence of a state of inorganic nature, favorable to man's continuance here, seems to be secured; so that for ourselves, and for long generations after us, we have nothing to fear. But the same forces of air and water, and of the volcanic interior, which produced former geologic revolutions, burying one series of living forms after another, still act upon the earth's crust. They, rather than those distant cosmical changes of which we have spoken, will put an end to the human race, and perhaps compel us to make way for new and more complete forms of life, as the lizard and the mammoth have given way to us and our contemporaries."

WATER-GLASS, OR SOLUBLE SILICATES.

Water-glass, or soluble silicate of soda, has come into use for a great variety of purposes. It is a most useful substance, and its nature should be better understood. We have recommended its use in the *Journal* for coating the inside of water cisterns, to prevent the cement from acting upon the water. This is an excellent application. It may be made of great service in many ways, which our readers will understand from the nature of the article.

There are four kinds of soluble silicates, namely, *potash, soda, double, and clear.* The first is composed of 15 parts pulverized quartz (a pure sand), 10 of purified potash, and 1 of powdered charcoal. These substances are first well mixed and exposed to a strong heat in a glass melting-pot for five hours, until the whole fuses uniformly; the heat required being about the same as that which melts glass. It is now lifted out, and when cool, it is broken in pieces and dissolved in about five times its bulk of boiling water. It is kept boiling for about three hours before it is all dissolved, and water is added as evaporation proceeds, so as to keep up the original quantity. It now becomes slimy, and in that state, or more diluted, is fit for use in many operations. It should be placed in well-stoppered bottles for use.

The second silicate is composed of 45 lbs. of pure quartz, 23 of anhydrous carbonate of soda, and 3 of powdered charcoal. This is fused in the same manner as the other. By substituting anhydrous sulphate of soda for the carbonate of soda, and using about eight times more charcoal, a cheaper silicate is formed, and both are soluble by boiling in water. Rectified alcohol precipitates the potash silicate from its water, and converts it into a solid silicate, which is dissolvable in water. The potash and the soda silicates mix freely with one another.

The double-soluble silicate is composed of 100 parts quartz, 28 purified potash, 22 neutral anhydrous carbonate of soda, and 6 of powdered charcoal. This mixture fuses much easier than the other two, but three measures of the potash silicate and two of the soda silicate described, when mixed together, will answer for all practical applications.

The fourth silicate, which is applied to fixing the colors of pictures, is made by fusing 3 parts pure anhydrous carbonate of soda with 2 parts of powdered quartz, which is boiled as described for the other silicates. This is kept in a concentrated solution, and one measure added to four parts of concentrated potash silicate completely saturated with quartz. By this means, silica and an excess of alkali are obtained, which, although more soluble, is clear, and not rapidly decomposed. This soluble silicate should only be employed in stereochromy-painting.

The first two soluble silicates, when mixed together, form an excellent cement with sand, and convert it into a stone-like mass. It is also excellent for filling up cracks in walls, as it acts very much like mineral glue.

When marble dust or chalk is made into a paste with water, then dried, and afterwards saturated with the silicate, it forms a compact mass, and acquires a hardness little inferior to solid marble, and it is capable of taking a fine polish, and water will not soften it. A mixture of marble-dust and the silicate of soda forms a cement which adheres either to wood or stone.

The oxyd of zinc and soluble glass combine with great energy, and form a paste capable of being rolled out and made into sheets to cover substances, such as wood, with a coat resembling polished slate. A patent has been taken out by a Mr. Hoard, of Providence, R. I., for writing-slates made of this composition.

One of the most important applications of water-glass is to painting. It enables the colors to adhere, renders them almost indestructible, and is therefore calculated to supersede fresco-painting. Some splendid mural paintings in the museum at Berlin have been treated with the soluble silicate; they are stated to be splendid works of art, and far in advance of fresco-painting for durability. Artificial sulphate of baryta, applied to glass by means of silicate of potash, imparts to it a milk-white color of great beauty; in a few days the silica is found intimately combined with it, and the color resists washing with warm water. By the action of strong heat, this silicious varnish is transformed into a fine white enamel. Blue ultramarine, oxyd of chromium and pulverized colored enamels may be applied. Silicious-painting upon glass is destined to find advantageous employment in the construction of church windows; while silicious-painting upon stone will serve for mural decoration.

The oxyds and metallic salts which enter into the composition of silicious colors or of cements have the property not only of combining with the silica of the silicates, but also of fixing, in an insoluble state, variable quantities of potash. The colors which act most energetically in this respect are the ochres; oxyd of manganese, oxyd of zinc, oxyd of lead, and artificial sulphate of baryta.

INTERESTING EXPERIMENT IN ELECTRICITY.

Procure four glass tumblers or common glazed teacups, and having wiped them dry as possible, hold them over the fire to evaporate any moisture which may still adhere to their surface; for if there is the least moisture it makes a connection, and spoils the experiment. Place them upon the floor in a square, about one foot apart; place a piece of board upon the tumblers, and have a person standing upon the board. This person is now completely insulated, the glass being a non-conductor of electricity. Now take a common rubber comb, and having wound a piece of silk around one end of it, rub it briskly through your hair, and draw the teeth parallel to the insulated person's knuckles, leaving a little space between the comb and the person's hand. The result will be a sharp, crackling noise, and if dark, there will be seen a succession of sparks. Repeat the process until the phenomena cease. The person is now "charged" with electricity, the same as a Leyden jar. To draw off the electricity, approach your knuckles to the person's hands or his nose (being careful not to allow any portion of your body to come in contact with his), and there will be a loud snap and the sparks will be very brilliant. If a cat be held so that the charged person can place his knuckles in proximity with the animal's nose, it will suddenly appear as if it were in contact with an electric battery. A glass bottle may be used in lieu of the comb, but it is not so well adapted for the purpose. Much amusement may be derived from this extremely simple experiment, and some of our numerous young readers will hasten to try it for themselves.

Defects of Building Materials in Relation to Health.—The author of an article in the *British and Foreign Medico-Chirurgical Review*, dwells upon the dangers of buildings constructed of materials saturated with saline matters. Among these materials are mortar mixed with sea sand, and imported lumber. Wood absorbs moisture very rapidly, and upon a sea voyage becomes charged with the saline deposits. The walls of buildings constructed of these materials are continually absorbing moisture, and by their dampness predispose rheumatism, phthisis, etc., etc.

Preparation of Litmus-Paper.—I have had much trouble in obtaining a thoroughly satisfactory litmus-paper. When used with blotting-paper, it is not as delicate as could be wished; and, on one occasion, when attempting to make it with sized paper, the blue tincture persistently turned red when it touched the paper. The latter reaction seemed to be due to the sizing material; and it occurred to me, that, if I sized some paper myself with pure gelatin, my object would be obtained.

I can recommend the following receipt:—"Digest 20 grm. litmus with 100 c. c. water for some time, shaking occasionally; then filter. To the filtrate add a slight excess of nitric acid, and boil; then neutralize exactly with potash. Now make a weak solution of gelatin, by boiling one part of isinglass with fifty parts of water; draw white blotting-paper through this, and hang it up to dry. When dry, paint one side with the above solution of litmus."—A. Vacher: *London Chem. News.*

Varnish for Iron-Work.—Dr. Lunge has published a method of making an excellent black varnish for iron-work. He distils gas-tar until nearly all the volatile products are got rid of. He then stops the distillation, and dissolves the residual pitch either in the heavier oils, or, if a very quickly drying varnish is required, in light oils or naphtha. This varnish is, of course, the original tar, minus the ammonia, water, carbolic acid, and other things which give it its disagreeable odor, and make it so long in drying.

Agriculture.

COMMERCIAL FERTILIZERS.

The season of the year is rapidly approaching when the attention of farmers and gardeners will be called to the important matter of providing fertilizing substances for their gardens and fields. The manufacturers of different substances, called phosphates, superphosphates, and artificial guanos, poudrettes, ammoniated mixtures, etc. etc., are actively engaged in filling their warehouses with heavy bags and barrels, in anticipation of an active demand for their products. Flattering certificates, so easily obtained, from governors, ex-governors, senators, officers of agricultural societies, well-known farmers and horticulturists are printed in handbills and widely distributed; and the advertising columns of agricultural journals are beginning to be filled with most enticing descriptions of new and wonderful fertilizing agents; each manufacturer representing his mixtures to be better than any others that have been, or can be produced. In all this, there is much to embarrass and confuse the purchaser, and often to lead him into unprofitable expenditures.

While it is true many commercial fertilizers have considerable value, or actually contain some of the mineral food which plants require, it is equally true that others are almost or quite worthless. The business of making and vending these products, as conducted in this country, is wholly empirical and wrong. There is no standard of value to any article, no formula by which, as a class, they are required to be compounded; and consequently every manufacturer follows his own caprices or cupidity, and is entirely irresponsible to custom or law. As between the manufacturer and consumer, the advantage is wholly on the side of the former, the latter having no means of detecting fraud. If a man buys a barrel of bad flour, its nature is ascertained upon first trial, and it is promptly sent back to the grocer; but if he buys a barrel of factitious superphosphate, he is never fully acquainted with the extent of the cheat. A manufacturer may continue the business of making worthless fertilizers for many years, and grow immensely rich, and yet escape detection. Indeed, he may gain even a *comfortable reputation* by adroit management in sending

good samples to prominent agriculturists for trial, and to chemists for analysis, and widely publishing the favorable results. There is in the products of many manufacturers great *inequality* in the fertilizing value of even the best specimens. This shows palpable and inexcusable carelessness, or else a design to maintain a reputation by introducing confusion in the results of trials; some proving good and others bad, the praises coming from the good specimens drowning the complaints arising from the others. Our husbandmen ought not any longer to be left in this unprotected condition. The thousands and tens of thousands of dollars wasted on valueless "superphosphates" and mixtures of powdered clam-shells and bones (the former often greatly preponderating), would be better employed in draining and reclaiming waste lands, improving farm buildings, or in securing materials for the compost heap. What is the remedy? We reply, every package of commercial fertilizing material offered for sale, should be *inspected* by a competent chemist, and its exact fertilizing value stamped upon it. The amount of nitrogenous, phosphatic, or potash value it may contain, should be distinctly stated, and a clear understanding of its chemical nature presented. Whenever a manufacturer has one hundred, or one thousand barrels of his products ready for the market, let the chemist take from each package a uniform specimen, and by mingling them together obtain a fair average of the whole, and then by analysis learn its value, and stamp the results upon each package. This would not involve much labor or expense, and would remove all chances of fraud, and greatly benefit the agricultural community. Laws ought to be passed this present winter, by every legislature, having in view the protection of farmers in the purchase of fertilizers. A plan can be devised, by which this desirable end can be reached, and it is high time it was entered upon.

PROGRESS IN AGRICULTURAL SCIENCE.

It is only fifty-eight years since the first accurate analysis of a vegetable substance was made, and about forty years since Liebig commenced to make reliable and systematic determinations of the chemical nature of plants and soils. The fact is almost incredible, that up to 1838 so little positive knowledge existed concerning the agricultural value of *ashes*, that the Gottingen Academy offered a prize for a satisfactory solution of the question, "*Whether the ingredients of ashes are essential to vegetable growths.*" How accurate, how minute is our knowledge of agricultural chemistry at the present time! and yet, it must be remembered, it has all been acquired in about thirty years. Who will venture to predict concerning the results of progress in the next thirty years? We are living in a remarkable age; and the laggards and dolts upon the farm or in the workshop have but poor chances in the race of life. Read, study, observe, experiment; many a valuable secret is yet to be extorted from nature, and the successful student is sure of his reward.

"HOW CROPS GROW."

How Crops Grow. By Samuel W. Johnson, M.A. New York: Orange Judd & Co. 1867.

American authors and writers are charged, by trans-Atlantic critics, with a want of originality in their productions. However true this may be of the contents, it ought not to apply to the *names* or titles of our books. Some years ago, Prof. Gray, of Cambridge, prepared a work with the title, "*How Plants Grow.*" This little treatise, so clear in its descriptions and statements, so simple, yet so thorough, has instructed and delighted thousands of readers. The taking title of the book drew attention to it on the part of those not usually interested in the topics of which it treated, and thus was secured a wide circle of readers. Now, we have another book, from Prof. Johnson, in "How *Crops* Grow." As "crops" are *plants*, the slight variation in name is hardly sufficient to distinguish it from Prof. Gray's book. We are sorry to see this appropriation of an attractive name of a work which rightfully belongs to another. It may be said that the books are essentially different—one being a botanical, the other a chemical treatise. This may be true; but it is a poor apology for the use of a name long associated with the work of another author.

Prof. Johnson's treatise, while presenting but few facts or principles new to students or readers of agricultural literature, is nevertheless a valuable work. It brings together, in convenient form for reference, much that is scattered through the periodicals and journals of this country and Europe; and the general arrangement of the matter is admirable. In preparing treatises useful to those engaged in the cultivation of the soil, it is important that writers should have practical acquaintance with farm labors and employments. When this experience is combined with high scientific accomplishments, the best possible qualifications are possessed for aiding with the pen the great interests of agriculture.

PLANT CORN.

In remarking that corn is a profitable crop to raise, we state what we know to be true. The knowledge is derived from fair and careful experiment, extending over a period of five years. We have grown corn under favorable and unfavorable circumstances; and, from accurate records and experiments, are fully convinced that small farmers and large farmers, those having good soils and poor soils, can raise Indian corn at a profit. Farmers are very apt to overlook the great value of the *corn-fodder* in forming their opinions of the importance of the crop. We estimate the value of this to be nearly or quite equal to the whole expense of cultivating the crop. It is certain, a ton of well cured corn-fodder will make as much milk when fed to milch-cows as a ton of good upland hay; and it is also certain, that young cattle thrive upon it wonderfully,—better, indeed, than upon most kinds of fodder fed to them during the winter months. We have always noticed a diminution in the flow of milk when the last of the fodder had been fed to our herd of cows, and also the *quality* of the milk deteriorates. Corn-fodder should be well cared for, and as much pains taken to preserve it in good condition as is taken with crops of clover or timothy. Corn should not be harvested too early, or while the stalks are green, as, in this case, they are certain to heat in the mow, and take on putrefactive change. Cattle will not eat them if they are mouldy and half rotten. As soon as the corn is removed from the husks, they should be thrown over, and mixed with wheat or oat straw and well salted. If salt marsh hay can be procured, mix considerable quantities of this hay with them, and thus prepared the fodder will be consumed with a relish.

Plant corn, we say. Prepare a few barrels of our *bone and ash fertilizer*, and place a handful in each hill, and it will start it vigorously, and sustain it through to maturity. We raised eighty bushels of good sound corn to the acre the past season, upon rather poor land, with the aid of this fertilizer. At the time of planting, a little earth should be sprinkled over the fertilizer, so that the seed may not rest directly upon it.

POWDERED BONES.

The inquiry so often made, how or where pure pulverized bones can be obtained, is one not easily answered. If any dealer or manufacturer has finely ground raw bone for sale, *which is free from all admixtures, or adulterations*, a ready market is open for it. So many letters of inquiry reach us relating to this point, they have become a source of considerable trouble and embarrassment. Raw bone-dust is prepared from dry bones, such as come from the hands of the soap boiler, or are picked up in the streets or fields. The powder contains, in addition to phosphate of lime, or the earthy portion of the bony structure, the *gelatine*, which is rich in nitrogen. In steaming bones prior to grinding, a large part of the gelatine is abstracted by the high-pressure steam, and therefore the powder is *not so valuable* for direct application to the soil, or for mixing with ashes to form the fertilizer recommended in the *Journal*, as the raw bone. For making superphosphate, or dissolving in acids, the steamed bone is the most valuable, as it contains a larger percentage of phosphate of lime. What is wanted for general farm purposes, *is raw bone ground to an impalpable powder, and free from all sophistication.*

AN EXCELLENT FERTILIZER.

We advise our readers, those who have farms and gardens to cultivate, to prepare as large a quantity of the fertilizer we suggested and recommended in the April No., Vol. II., of the *Journal*, as they possibly can. It embraces in its composition quite every element required in the growth and maturation of roots and the cereal grains; and it has the advantages of being comparatively cheap and easily prepared. No fertilizer we have yet devised—and we have prepared and experimented with a large number—affords more certain and satisfactory results than this one; and those who prepared and used it last season are extravagant in their praises of it. It supplies a most desirable dressing for fruit-trees and vines. We use no other fertilizer for our grapes; and if any of our friends have had better results in their cultivation than we have, it will afford us pleasure to publish their successes. The method of preparing the fertilizer is as follows:—

"Take one barrel of pure, finely-ground bone, and mix with it a barrel of good wood ashes; during the mixing, add gradually about three pailfuls of water. The heap may be made upon the floor of an outbuilding, or upon the barn floor; and, by the use of a hoe, the bone and ashes must be thoroughly blended together. The water added is just sufficient to liberate the caustic alkalies, potash, and soda; and these react upon the gelatine of the bone, dissolving the little atoms, forming a kind of soap, and fitting it for plant aliment. It must be used in small quantities, or in about the same way as the so-called superphosphates. A barrel of this mixture is worth two of any of the commercial fertilizers, and the cost will be but about half as much. It remains to be added: if the bone-meal and ashes are very dry, four pailfuls of water may be required; but care must be exercised not to have it inconveniently moist. It will be ready for use in a week after it is made. *Pure, raw, finely-ground bone* and the best of ashes should be employed."

Setting out Trees in Winter.—A writer in the *Cultivator and Country Gentleman*, says that last winter, in January and February, he set out over 200 trees, bass-wood, elm, hard and soft maple. Of these not one failed to leaf out and grow; but about 10 per cent died during the hot weather of July and August. He chose mild days and covered up the trees while moving them, as they had to be carried about two miles. When the day was too short for him to finish his load, he dug through the snow, set the trees on the bare ground, covered well with snow, and left them till next day. Transplanting trees at a time when the ground is frozen, may be more laborious than during the spring, but in winter farmers have a good deal of time on their hands, and a little of it spent in planting trees in the vicinity of their houses, will be amply repaid by the grateful shade in succeeding summers.

Boston Journal of Chemistry.

BOSTON, FEBRUARY 1, 1869.

☞ Any one sending us the names of three subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For five subscribers we will send the Petite Microscope; for twenty-five we will send, in addition to the microscope, a copy of "Stöckhardt's Chemistry for Students," the best elementary treatise yet published; for one hundred subscribers we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stöckhardt's Chemistry.

☞ Physicians, students, clerks in drug-stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

☞ Correspondents are particularly requested to give their names in full, with their Town and State; and, in case of change of residence requiring a corresponding change in the mailing of their papers, to give not only the new address, but the old one also.

☞ Subscribers who are physicians, dentists, or apothecaries, will confer a favor by informing us of their profession, as we wish to know accurately the amount of our medical subscription list.

NO CHANGE IN THE "JOURNAL."

It was stated in the last number of the *Journal*, that, at the commencement of Vol. IV., in July, it would be enlarged, and the price raised to one dollar. As will be learned from the Prospectus, we have decided to make no changes. Subscriptions are pouring in upon us so rapidly, and the favor with which the *Journal* is received in its present form is so marked and unmistakable, we have decided to follow the wise maxim of "letting well enough alone." *It is true*, as is often remarked by correspondents, that "THE JOURNAL IS THE PAPER FOR THE MILLION, *and a copy should be in every family in the United States*." Friends and readers, help us to accomplish the desirable end of placing it in every family. There is hardly one so poor as not to be able to spare the small sum of *Fifty Cents* a year; and how much reliable, useful information would be gained by every one, from its perusal from month to month! Friends and readers, this is YOUR PAPER. The publishers, even with its large circulation, receive barely sufficient to keep both sides of the ledger balanced, so low is the subscription price. We have at present fully

FORTY THOUSAND READERS!

With your efficient aid, we can have, in five years,

HALF A MILLION

readers. Send in the names! See Prospectus in another column.

BACK VOLUMES OF THE JOURNAL.—We are unable to supply complete files of either Vol. I. or II. of the *Journal*. Of Vol. I. (originally issued bi-monthly), Nos. 1 and 2 are now out of print. Of Vol. II. (monthly), Nos. 1, 3, and 12 are also out of print. Of the remaining numbers we have a few copies left, which we will forward to our friends at the following prices: Vol. I., four numbers, twenty-five cents; Vol. II., nine numbers, fifty cents. We have on hand a few complete files of Vol. III., as far as published. These we will send as ordered, at the rate of six cents per single copy; six copies for twenty-five cents.

ELECTROTYPING THE JOURNAL.—The demand for past issues of the *Journal* is so large from new subscribers, it has become necessary to stereotype or electrotype each number. We shall commence electrotyping with Volume IV.

PROSPECTUS.

BOSTON
Journal of Chemistry.

Vol. IV.—Commencing July 1, 1869.

A PROSPECTUS OF VOL. IV. OF THE "JOURNAL," is issued at an early date—five months before the volume commences—with the view of informing our numerous friends regarding our plans in the future, and affording them ample time to aid us in extending its patronage, and consequent usefulness; besides, it enables us to make a very generous offer to new subscribers, the nature of which is stated below.

A very general desire has been expressed that the JOURNAL should be continued in its present form at least through another year; and, after much deliberation, it has been decided not to make the contemplated change alluded to in the January number.

VOLUME IV. of the JOURNAL, commencing July 1st, 1869, will be of the same form and size as the present volume, each number containing not less than *nine pages* of reading matter. It will be printed with new type, on the finest book-paper; and we shall strive to make it not only the *best and cheapest scientific journal in the world*, but the *handsomest*.

The terms for the JOURNAL *will be the same as heretofore—Fifty Cents* (50) *per year; single numbers, Six Cents.*

The JOURNAL will continue to be independent, unbiased, careful and reliable. No individual, corporation, or organization, is rich or influential enough to suppress its opinions, or in any way control its influence. It will continue to expose frauds, schemes, and speculations, which profess to originate in or grow out of progress in science and art. The great and growing evil of *adulterations* in articles of food, medicine, fertilizers, and substances used in the arts, will receive special attention, and the nature of the sophistications and adulterations fully exposed. We shall present a large number of useful practical formulæ, recipes, and scientific suggestions, which alone will be worth many times the price of the publication.

TO PHYSICIANS,

It will continue to be of *special service*, as it will keep them informed of the nature of all new remedial agents, all new discoveries in chemical and medical science, all new principles or processes connected with toxicology and pharmacy.

TO DRUGGISTS,

It will come as a reliable friend and adviser, affording information and instruction upon all matters relating to the manufacture and dispensing of medicines, and those other substances and agents produced or vended by them.

TO FARMERS,

It will impart information upon the important subjects of the chemistry of plant-growths, and the nature and method of preparing fertilizing agents.

TO CHEMISTS, MANUFACTURERS, ARTISTS, TEACHERS, STUDENTS, CLERGYMEN,

ALL intelligent readers, men and women, everywhere, the *Boston Journal of Chemistry* will supply information and instruction of the highest importance and usefulness.

The JOURNAL has, at the present time, a large army of friends, and these we ask to aid us in extending its circulation. Our patrons know how instructive and useful it *has been* in the past: we assure them it will be even *better* in the future. Cannot each one send us a new subscriber, to commence with Vol. IV.?

We make this generous offer to *new subscribers*: All those who subscribe, and send us *fifty cents* in advance, will receive the remaining numbers of Vol. III. They will receive the whole of Vol. IV., and all the numbers of Vol. III. which are issued after the date of their subscription. *Subscribe early*, and thus obtain as a gratuity, nearly half of Vol. III.

JAS. R. NICHOLS & CO., Publishers,
BOSTON.

ABOUT STOVES.

"What stoves shall we use in our dwellings?" This is a question often and anxiously asked by housekeepers and heads of families, as the cold weather of winter approaches; and, indeed, it is a question of no ordinary importance. The two desirable points in stoves or heating apparatus of any kind, are, *first*, economy in consumption of fuel; *second*, the evolution of heat in a form, or under conditions, conducive to health. In selecting a parlor stove, the first consideration is too often allowed to have a preponderating influence; and if the dealer can satisfy the purchaser that a stove, by any peculiarity of flues and dampers, will save even a small amount of fuel, it is purchased in preference to one more philosophically constructed, or one better adapted to diffuse an equable temperature, and allow of a free escape of the products of combustion into the flue. The stoves, as a class, which obstruct draft by circuitous flues and a multiplicity of valves, or which feed fuel in an unnatural manner, are such as should be avoided in making a selection. How often, in our evening visits to neighbors and friends, do we find the family dozing in a half-asphyxiated state, in a room charged with carbonic oxide, carbonic acid, and sulphurous acid gases, proceeding from a stove with "new patent double back-action transverse return flues, and combination automatic air-valves," which some enterprising inventor has just "brought out"! We doubt if any fuel is really saved in such devices. If there is a saving of a few pounds of coal a week, it is at the expense of health and comfort; and this kind of economy costs fearfully high.

Chemists have had much to say about the immense loss of heat in the escape of the unconsumed gases from stoves; and their statements are in the main correct. There is considerable loss from incomplete combustion in the use of fuel. This fact being generally understood, a whole army of inventors come forward with their "gas-consuming" stoves, and the warehouses of dealers are full of them. We have never yet seen a *safe* and *practical* stove of this description,—one that we would use or recommend; and we have examined many devices. There are practical difficulties in the way of consuming gases in stoves; and we must be content to suffer some loss of heat, so long as attempts to save it result in danger to the life and health of families. A stove with few complications, constructed of sheet-iron, is, after all, the safest and best. It has been proved by satisfactory experiment, in this country and Europe, that *cast-iron* is permeable to the poisonous gases resulting from combustion; and therefore, stoves constructed of this metal, which are to be used for household warmth, should be rejected. No more comfortable or economical wood-burning stove has ever been devised than the old-fashioned "air-tight," which were so common twenty years ago. If provision is made for ventilation, this stove may be used with entire safety, at comparatively small expense. It causes little trouble, and affords much comfort. The new "soapstone stoves," we are reluctantly compelled to condemn, as too *wasteful* of fuel, too costly, and liable to crack badly. We have two of them in use; and practical experience and experiment confirm our views regarding them, formed several years since. The almost colorless, smooth, greasy outside of soapstone stoves affords the most imperfect heat-radiating surfaces it is possible to conceive of. The waste of fuel in these stoves is enormous. From some incomplete experiments made with the view of ascertaining the amount of loss, it is inferred that, under the ordinary conditions in which these stoves are used, at least two

thirds of all the heat developed is forced into the flue, along with the products of combustion. A small stove of this description, connected with an iron galvanized pipe passing twenty feet through two cold rooms, raised the temperature above 200° F. at the inlet to the flue. There are some desirable points in these stoves, such as the slowness with which heat is evolved, the persistency with which it is retained in the stone walls after combustion ceases, etc.; but these advantages do not compensate for the disadvantages alluded to above. Wood is, as fuel, so much more healthful and desirable, it is a pity it cannot be more generally used. The difference in the sanitary condition of a family, other things being equal, where a good blazing wood fire is maintained upon the hearth, is most marked, when contrasted with one using hard coal in connection with the stoves in common use. So long as there is a necessity resting upon tens of thousands of families, to use only this kind of fuel, it is of the highest importance that the stoves in which it is burned should be properly constructed, having a free, clean draft, and no unnecessary, dangerous "dampers" to jeopardize life and health.

Patent Butter Association.—The need of the diffusion of more practical scientific information among all classes is clearly shown, in the readiness with which people become victims to some of the most absurd tricks and schemes which the fertile brains of cunning men can invent. The most recent of these tricks surpasses in audacity all others which we ever heard of. A *Patent Butter Co.* have opened offices in this and other cities to show people how to make *a pound of good butter out of a pint of milk*, and to sell them *rights* to make, and also *a little white powder*, which is the agent used to perform the magic work. At the office of the Co. they do not ask the eager purchasers to believe their statements, but they *churn out the butter before their eyes*. A pint of milk, *with half a pound of good butter*, is put into a little tin churn, with a spoonful of the powder, the whole is *warmed*, and then five minutes' churning brings out *one and a half pounds* of good butter! Here is demonstration! what can be more convincing? No one suggests to the enterprising Co. that nearly *nine tenths* of the milk used, is *water*, and if they perform what they allege, they are changing *water into butter*. This would indeed be a miracle, equal to that of our Saviour, who changed water into wine. We have been asked many times by *intelligent* gentlemen, how this thing can be explained. Very easily. By the process, the whole of the pint of milk (mostly composed of water) is driven into or blended with the half pound of melted butter, put into the churn. There is no important increase of real butter in the churn, although the watery mass which looks like inferior butter, weighs more. Put the mass into a dish and heat it, and the true butter will separate from the milk or water, with which it is blended. This is the method by which butter and *lard* are greatly adulterated. Nearly all the lard sold by grocers, contains from 25 to 40 per cent of *water*. The adulterators have not been able until within a year or two, to combine with genuine lard more than 25 per cent of water; but recently, by the use of the alkaline carbonates, partly saponifying the lard, they force into association *more than* 40 *per cent*. What a shameful fraud this is! and how hard it falls upon poor people, who mostly consume the attenuated fat! We shall wage unceasing war upon these wicked frauds and schemes, and we ask all honest men and women to aid us in exposing, and thus preventing the evils.

Tin-Lined Lead Pipe.—A correspondent informs us that the *N. Y. Tribune*, in a recent article upon this new variety of pipe, took opposite grounds from those maintained in the *Journal*, and ridiculed the idea that it was unsafe to be used for the conveyance of water to dwellings. With a section of tin-lined lead pipe lying upon the desk before us, taken from a well in a neighboring town, so corroded by galvanic action as to cause lead poison in those using the water, we are not likely to modify our views, or be very much influenced by any statements of interested parties, presented through the columns of the secular press. The *Journal*, so far as our observation extends, is the only paper which has explained or exposed the nature of this peculiarly constructed water pipe, and our views are supported and endorsed by the best *practical* scientific men in the country. Better than this, they are proved correct by the results of laboratory experiments, and by actual trial of the pipe in locations where it has been placed by the makers or venders. The matter of safety in water supply pipes is far too serious in its bearings upon the health of families and individuals, to allow private interests to wrongfully influence the public mind, and we shall continue to do what we can to disseminate correct information upon this and all others subjects of interest to our readers.

Carbon.—The element carbon is possessed of extraordinary capabilities, among which its distinctive property of *uniting with itself* to form complicated compounds is the most striking. An aggregation of carbon atoms is found united with hydrogen, oxygen, nitrogen, forming distinct chemical bodies, or groups of atoms, which play, in organic chemistry, a part similar to that of the *metals*, or the simple molecules, such as the radicals NO^2 and SO^3, met with in the inorganic department of the science. These molecules, or groups of atoms are called *compound radicals*, and they act as if they were elements. Carbon is called a *tetrad*, or tetratonic element, and its powers of combination, or atomicity, differ entirely from the *monads*—chlorine, potassium, silver—and the *dyads*—oxygen, sulphur, and magnesium. We must regard carbon not only as one of the most extraordinary of the elementary bodies, but as one of the most important. Organic chemistry without carbon would be like the solar system without the sun.

Complete Steam Atomizer.—A very neat, durable, and convenient instrument is the "complete steam atomizer," made by Messrs. Codman & Shurtleff, of this city. A careful examination and trial of this atomizer convinces us that it will be difficult to construct a better one, and its low price ($6.00) brings it within reach of every physician. The surgical and dental instruments made by Messrs. Codman & Shurtleff stand deservedly high in the estimation of medical men, and their articles find a ready sale in every part of the country.

State Assaying.—The question is often asked, if the numerous certificates relating to hair oils, tooth powders, root and herb medicines, etc., etc., which are found in handbills and newspapers, signed by one or more of our *State Assayers*, are *geniune*,—if they really supply the quacks with such documents. We wish we had, for the honor of true science, and the reputation of the Commonwealth, direct authority to declare them all fraudulent, and the tricks of advertising mountebanks. We have no such authority, and we have never seen any disavowal of them from the parties interested.

The "Wagon" Cement.—A new device for making a sensation, and "raising the wind," has recently been noticed in the streets of our cities and large towns. A wagon loaded with hay or wood, is drawn about, covered over with placards extolling a wonderful cement, the practical value of which is proved by the fact that the leather traces by which the load is drawn, are held together by the cement. This cement is a well known and very simple article, made by taking the common fish glue, dissolving it in an equal weight of warm water, and to each pint of this solution adding two fluid ounces of alcohol, and half an ounce of gum mastic dissolved in a little alcohol. Mix thoroughly and keep in a well stopped bottle. It is a good cement for many purposes, when continued moisture is not present, but it it is much cheaper to make than to buy it of the wagon pedlers.

Breeding Ostriches in Algeria.—M. C. Rivière, Director of the Gardens of Hamma, near Algiers, has succeeded in rearing ostriches in a park supplied with a palisade enclosure containing a quantity of fine sand. Before depositing her eggs, the female ostrich seems uneasy, and seeks a suitable place. She forms a small hillock of sand, slightly concave at the top, and lays one egg in it, to which she afterwards adds others. She lays every two days for two or three months, with an interval of repose. Incubation lasts forty days, during which time the male and female sit alternately. On the 12th of March, five were hatched, and three the day after. At the end of May some of the ostriches had laid their fiftieth egg. The males take great interest in the incubation, and only leave the eggs when pressed by hunger, and then the females take their place, but not for such long periods. An extra circulation goes on in the uncovered portions of the male's body, to generate the heat necessary for the process.

Gum Arabic.—We have gathered some fine specimens of this gum the present winter from trees growing in a conservatory. The species which produces it is known as the *acacia cultiformis*, a very remarkable shrub or tree, of rather slow growth, affording, at the period of inflorescence, beautiful pendent flowers, of a dazzling yellow color. The gum exudes from incisions made in the bark, and is hardened by exposure to heat and air. To produce gum in any considerable quantity, the shrub must be planted in a sandy soil, and subjected to quite a high temperature.

Map Varnishes.—A very good varnish for covering over architectural and mechanical drawings, maps, etc., can be made by dissolving one pound of white shellac, a quarter of a pound of camphor, and two ounces of Canada balsam in one gallon of alcohol.

The following method affords also a good, quick-drying varnish: Thin down Canada balsam with turpentine, and add one fourth of the bulk of quick-drying, pale copal varnish; lay on smoothly with a flat camel-hair brush, and let the map lie flat for a few hours.

Liebig's Extract of Meat.—The establishment on the river Uruguay, South America, for the manufacture of Liebig's extract of meat, it is stated, has the largest kitchen in the world. The building covers an area of 20,000 square feet, or nearly half an acre. In one hall there are four meat cutters, which can dispose of 200 bullocks each per hour. There are 12 digesters, in which the meat is boiled by steam. They can hold altogether 144,000 pounds of beef. About 80 oxen per hour are actually slaughtered for this immense manufactory of meat extract.—*Med. and Surg. Reporter.*

The Spectrum of Lightning.—Lieut. John Herschel has communicated to the Royal Society an account of the spectrum produced by lightning. He says: "The principal features are a more or less bright continuous spectrum, crossed by numerous bright lines—so numerous as to perplex one as to their identity."

Five Thousand Dollars saved by taking the Journal.—One of our subscribers in a neighboring city, who had become interested in a certain scheme or speculation, concluded to invest five thousand dollars in the same, and had made arrangements with the parties to pay over the money. The night before the payment was to be made, the August number of the *Journal* came to hand, and the editorial article upon "schemes" and "speculations" met his eye. This clear exposure of the character and dangers of speculative schemes arrested his attention, and led him to pause before paying over the money. It was not paid, and in less than a month the plausible speculation *failed*, and every dollar invested was lost. Our subscriber thinks the *Journal has been worth to him fully* 50 *cents a year*.

Sea Depths.—Soundings for submarine cables show that the Baltic, between Sweden and Germany, is 125 feet deep; the Adriatic, between Venice and Trieste, 130; the English Channel, 300; the Irish Sea, in the south-western part, 2000; the Mediterranean, east of Gibralter, 3100; off the coast of Spain, 6200; by the Cape of Good Hope, 15,500.

☞ Letters come to hand by every mail, in which the *Journal* is spoken of in flattering terms. Many of the most distinguished men of the country manifest special interest in the publication, and write regarding its "interesting," "useful," "reliable" character. John G. Whittier, the poet, kindly writes as follows: "I take pleasure in commending this admirable journal, which, as might be expected, from the high character of its editor as a practical scientific man, is every way worthy of support. It treats subjects which concern the health and comfort of all; and while it is the cheapest, it is really one of the best publications of the day." Professors, teachers, farmers, physicians, all classes unite in sending words of kindness and encouragement. One says, "I would not be without it if the price was *ten dollars* a year." Another, "It has saved me many dollars by its valuable suggestions." Another, "Regard me as a perpetual subscriber; myself and family cannot do without the *Journal*." We could fill pages with extracts from such letters. We assure our many friends that we shall do what we can to continue the publication an "interesting" and "instructive" journal of practical science.

Molecules and Atoms.—In communications which have appeared in respectable scientific journals, we notice that the terms *molecule* and *atom* are often used synonymously, as if they signified one and the same thing. A *molecule* is a group of atoms forming the smallest portion of a chemical substance, either simple or compound, that can be isolated, or that can exist alone; it is the smallest amount of substance that can enter into any reaction, or be generated by it. An *atom* is the smallest portion of an element that can exist in a compound body as a mass indivisible by chemical forces. For instance, no such thing as an *atom* of *water* exists; a *molecule* is the smallest portion of this compound body possible; and this, H^2O, contains *two* atoms of hydrogen. It is important that accuracy should be insisted upon in the terms employed in scientific statements.

BOOK NOTICES.

Diseases of the Liver; Jaundice and Abdominal Dropsy. By Charles Murchison, M.D., F.R.S., Fellow of the Royal College of Physicians, etc. New York: William Wood & Co., Publishers. 1868.

In the form of lectures to the students of the Middlesex Hospital, the important facts and suggestions of this work have been before presented by Dr. Murchison, and several of the lectures have also appeared in the pages of the London *Lancet*. The object of the treatise is to put prominently forward the leading characters upon which the diagnosis of diseases of the liver depend, such as enlargement, jaundice, dropsy, pain, etc. Hepatic disorders are fearfully increasing in this country, caused, we suppose, by abnormal excitements of the nervous system, and by over-feeding. Physicians will find many useful hints for the proper treatment of these diseases in Dr. Murchison's book.

Use of the Laryngoscope in Diseases of the Throat. With an Essay on Hoarseness, Loss of Voice, etc. By Morrell Mackenzie, M.D., London. With Additions, by J. Solis Cohen, M.D. Philadelphia: Lindsay & Blakiston. 1869. Second Edition.

In another column of the *Journal* we have presented some brief statements regarding the use of the laryngoscope, its construction, history, etc., which were written before this work fell into our hands. Those who desire a thorough treatise upon laryngoscopy, illustrated with cuts and plates, will consult the pages of this beautifully printed book. We have never seen a more perfect specimen of book-making in the department of medicine than this work presents. The type, paper, engravings, and general style are admirable, and reflect great credit upon Messrs. Lindsay & Blakiston, the enterprising publishers.

On Chronic Bronchitis, especially as connected with Gout, Emphysema, and Diseases of the Heart. By E. Headlam Greenhow, M.D., Fellow of the Royal College of Physicians, etc., etc. Philadelphia: Lindsay & Blakiston. 1869.

The readers of the *Lancet* will remember these lectures, as they appeared a year or two ago. They were read with much interest and profit by hundreds of medical gentlemen, who will be glad to know that they have re-appeared in book form. A prominent design of the author is to show the intimate connections between chronic bronchitis and certain constitutional and local conditions of the system. This is accomplished in a very clear and satisfactory manner.

The Physician's Dose and Symptom Book. Containing the Doses and Uses of all the Principal Articles of the Materia Medica and Officinal Preparations. By Joseph H. Wythes, M.D. Eighth Edition. Philadelphia: Lindsay & Blakiston 1868.

A very convenient little manual; one which every physician needs for ready reference in the office and at the bedside of the patient. Seven editions have been sold, which affords evidence of its great utility.

Pronouncing Medical Lexicon. By C. H. Cleavland, M.D. Eleventh Edition. Philadelphia: Lindsay & Blakiston. 1869.

This is the eleventh edition of Prof. Cleavland's well known medical lexicon, a work which was greatly needed when it appeared, and which has been of much service to thousands of readers of medical literature in every part of the country. The size is convenient for carrying in the pocket, if desired.

Curious Statements Regarding Dyspepsia.—Dr. Fenwick (on the morbid states of the stomach and duodenum) gives some curious statistics, proving that moderate smoking does not injure the digestion, but is, on the contrary, often useful in relieving constipation, apparently from its property of stimulating the nerves. Also that dyspepsia appears to be very common among teetotalers, and that a moderate use of malt liquors is eminently useful, especially to females. Excess in coffee appears to be peculiarly injurious. Stout people suffer more than thin people from dyspepsia.

Medicine and Pharmacy.

ABOUT THE LARYNGOSCOPE.

It is difficult to comprehend the immense advances that have been made in medical knowledge for the last two or three decades, particularly in the department of physical exploration.

When, not many years ago, Dr. Horace Green, of New York, announced that a probang could be introduced into the living windpipe, through the throat, his statement was almost entirely discredited. Wise physicians declared it impossible; and it was only after the New York Academy of Medicine had given a thorough and searching investigation, that the assertion was pronounced possible.

Had Dr. Green lived at the present time, and made a similar announcement, he would have met with the same reception as if he had stated the possibility of passing a probang into the œsophagus. The domain of the living body is now penetrated at every natural inlet, and the eyes of the modern physician see sights which their predecessors longed to see, "but died without the sight." The microscope reveals diseases of the solids and fluids, of the cutaneous surfaces, and of the surfaces and substance of glands buried deep out of sight. The stethoscope and sphygmoscope reveal abnormalities of the respiratory and circulatory organs. The ophthalmoscope tells of lesions in the depths of the eye. The endoscope shows stone in the bladder. The urethroscope manifests the changes of structure in the urethra, and the laryngoscope in the larynx.

The term *laryngoscope* is a formidable name for a very simple instrument. It is nothing more than a round mirror which is small enough to be held in the back part of the mouth. It is mounted on a wire, at an angle of about 145°, and is provided with a handle. When this mirror is held as above, at about an angle of 45° with the horizon, the reflecting surface presenting forwards, and a horizontal beam of light is thrown upon it, the effect is to illuminate the larynx and the parts behind the tongue, and to render them visible to the eye of an observer.

This is a great advance in the inspection of the throat, and already ripe fruits have been reaped in this hitherto unknown living field. Only to think that it is possible to see the vocal cords in *situ naturali* and in action, and not only to see, but to study them during their physiological action! We can tell by the sirene the number of vibrations per second of time that are made by these vocal cords during the utterance of a musical note, and, at the same time, we can see the vibrating chink. A diagnosis of the cause of hoarseness can be made. Sometimes it has been found to depend upon excrescences or warts growing in or upon or about the larynx. Some of the most successful feats of modern surgery have been performed in this field, the patients recovering their breath and voices almost instantly upon the removal of these warts or excrescences!

The history of the discovery of physiological laryngoscopy dates back to 1854, when M. Garcia, a celebrated London teacher of music, discovered that he could see his own vocal cords, by means of a mirror held in his mouth, when a powerful beam of light was thrown in on to it. His discovery and observation were communicated to the Royal Academy for that year, and were published in their transactions. They excited but little attention from the medical world; but Dr. Turck, of Vienna, had some mirrors made according to his ideas, and experimented on himself, trying to repeat Garcia's investiga-

tion, but entirely without success. At this stage, Prof. Czermak, of Prague, in Bohemia, borrowed Turck's mirrors, and tried them. He succeeded perfectly. He is called the father of laryngoscopy; and to him is rightly due the credit of having made the art available. He travelled about the continent, making it known, and freely giving all the information he could. Turck, finding Czermak succeeded so well, resumed his trials with success, and disputed the claim of discovery with Czermak. Various persons have also disputed the same claim, unearthing old dead and buried instruments and notions which would have remained so to this day, had it not been for Czermak. At about the same time, in this country, Dr. E. Cutter, of this city, invented a laryngoscope, which was made for him by the celebrated firm of Alvan Clark & Son, of Cambridgeport. He was the first cis-Atlantic, as far as our knowledge goes, to discover the principles of the instrument.

At the present day, the business of inspecting the larynx and posterior parts has arisen to the dignity of a special art; and, in the most populous civilized cities of the world, there is now a large corps of earnest, distinguished, and successful laborers. Diseased conditions have been disclosed which were unknown before, or mistaken for other abnormalities, and which hitherto were allowed to run unchecked. The old method of swabbing the throat in the dark, by guess, so much like the process of cleaning out a chimney, is now in disrepute; while in its place is adopted a scientific and exact application of remedies to the site of the disease, under sight, and nowhere else. The physician treats the affections with more confidence, as he can watch the progress of the disease, see the effect of applications, and determine with definiteness the pathological condition.

From this brief survey, it will be seen that no one who has a serious affection of the throat ought to allow it to go on without giving himself the benefits of a thorough examination with the laryngoscope.

We wonder that more physicians do not employ the laryngoscope. The apparatus and the principles are of the simplest description. It only requires patience and perseverance. It is estimated that fifty per cent of all the cases can be examined by any intelligent and careful manipulator. The remaining fifty per cent require experienced and skilful hands; a small proportion being entirely beyond the abilities of any one.

The difficulties are mainly subjective, and arise from irritability and involuntary movements of the tongue, which has always had the bad reputation of being an "unruly member."

To illustrate the value of the laryngoscope, we will relate a single case: — Some five years since, a young lady of this State became hoarse while teaching school, and finally lost her voice entirely. She consulted a number of eminent physicians, who, without the laryngoscope, made their diagnosis and began their treatment, without any good results. She went from one to another, till the last consulted employed the laryngoscope. This revealed the cause of the loss of voice to consist in a large tumor growing in the larynx, and arising from the vocal cords. It was so extensive that it became necessary to remove it by cutting into the larynx from the outside. This was successfully done; and now, at the expiration of two years and a half of time, the lady is alive and in the constant enjoyment of the use of her voice.

In the *Journal de Chimie* is reported the case of a girl, eighteen years old, poisoned by eating a few of the common domestic flower called the buttercup.

BENZOATED OINTMENT OF THE OXIDE OF ZINC.

Editor Journal of Chemistry: —

The discovery that gum benjamin prevents ointments from becoming rancid is one of the most beautiful, satisfactory, and important of the late contributions to dermal pharmacology. A rancid ointment is irritating to the skin, unpleasant to the eye, and disgusting to the nostrils. It generally receives its appropriate deserts by being cast out as worse than worthless. On the other hand, ointment without rancidity is attractive to the senses. Its purity and freshness soothe the inflamed integument, and allay the irritation. No one ever heard any thing said against the use of unguents when freshly and properly prepared; but when they have lost their virgin freshness, and oxidized into the various stages of chemical changes, from margaric and stearic acids into butyric, etc., their reputation undergoes a similar metamorphosis from good to bad. Thus ointments have fallen into disuse, not from their inherent qualities as first made, but from those features which they acquire by age.

The gum benjamin, as has been stated, arrests these changes, although used in a relatively small proportion to the whole mass. About one grain of the powder to forty-eight of lard is employed. This gum is, according to Wood & Bache's Dispensatory, obtained from the "benjamin-tree, a native of Sumatra, Java, Borneo, Laos, and Siam. By wounding the bark near the origin of the lower branches, a juice exudes, which hardens on exposure, and constitutes the benzoin of commerce. Its chief constituents are resin and benzoic acid; and it therefore belongs to the balsams. It has a fragrant odor, and in the East Indies is burnt by the Hindoos, as a perfume in their temples."

Preparation. — There are two methods of preparing the benzoinated lard, each exceedingly simple. In the first place, the lard should be of the best description. I say *should*, for once, needing some of this ointment for immediate use, and having only lard which had *already become* RANCID, I thought I would try the experiment, to see whether the benjamin would not redeem the lard from its rancidity. It did so. This is a fact worth remembering, and has not hitherto, to my knowledge, been published.

The first process is to take the pulverized gum and lard in the proportion just mentioned; i.e., ten grains to the ounce; place them together in a covered vessel, and then heat over a sand or water bath gently for twenty-four hours, and strain through a fine sieve into another vessel. The finely pulverized oxide of zinc, in the proportion of one ounce to six ounces of lard, is next added, gradually, and as it cools it is to be occasionally stirred with a spatula, so as to insure a uniform diffusion.

The next process is to mix the tincture of benzoin (℥vi. to Oj alch. fort.) directly with the lard, fifteen minims to the ounce, and add the zinc as before. This is considered the most elegant process. However, it does not seem to give that body which the first process secures. This subject has been pharmaceutically studied by Mr. Thomas Doliber, of T. Metcalf & Co., of this city. His labors have been published in the Transactions of the American Pharmaceutical Association for 1866–7. They are entirely satisfactory and exhaustive, and show beyond a cavil the inestimable value of the benzoin in preserving unguents.

Different ointments were prepared with benzoinated lard, and Mr. Doliber, in his carefully conducted test experiments, found that uniformly they kept their freshness in a manner that no other process ever secured. He kept them in a hot place for months, and yet such an unstable ointment as the ung-hydrargyrum refused to become rancid.

The benzoated ointment of oxide of zinc he says, "was not experimented upon, *as, from long experience, I have never known the benzoinated preparation to change;* while it is well known that the officinal ointment *very soon becomes rancid.*" Wilson, the most eminent English dermatologist says: "The benzoated oxide of zinc ointment properly prepared is the most perfect local application for all chronic inflammations of the skin that is known. It is cleanly, agreeable, of a cream-white color, not diffluent and oily like other ointments; and it has a tendency to concrete upon the skin, and constitute an artificial cuticle to an irritated and denuded surface."

An experience of ten years in general practice allows the writer to corroborate this statement. Too much cannot be said in praise of it; keeping for an indefinite time, it is always ready for the use of its normal healing virtues in any case in which it is needed. It is thus a reliable ointment. Its reputation is exceedingly good in the profession, and it is most remarkable that it is not kept for sale by every apothecary throughout the land.

This may be explained in part by the fact that an impression has gone forth that it is an exceedingly difficult preparation to make; and hence when called for, the druggist dishonors the prescription, or sends to T. Metcalf & Co. to have it filled. It finally would be wisest for each pharmaceutist to make it in his own establishment, so that it may become a household word, much better for burns, scalds, erythems, and exanthems, than Russia Salve or Holloway's Ointment, which have such extensive sales. It is useful in the various varieties of eczema, porrigo, and psoriasis; also to wounded, chapped, excoriated, irritated, and inflamed cutaneous surfaces, — a good substitute for "cold cream."

From what has been hinted, it is hoped that the benzoated oxide of zinc ointment may come into more general use. It certainly has been put to the most crucial tests, and has not been found wanting; and in these days of positiveism and progress, such a tried reputation ought to be a passport for it into every druggist's jar and physician's prescription paper. E. CUTTER, M.D.

BOSTON, Mass.

ELECTRICITY IN SEA-SICKNESS.

Within the past few weeks, directions for the cure of sea-sickness have been going the rounds of the papers, which, if completely carried out, would involve the necessity of the patient lying flat on his back, the entire voyage. We find in the *N. Y. Med. Journal*, a description of the process adopted by Dr. Le Coniat, surgeon of the Imperial French Navy, now serving as surgeon of one of the steamers on the French line between Brest and New York.

Dr. Le Coniat's theory is, that sea-sickness is induced by electric disturbance throughout the system, and that vomiting at these times is induced by an involuntary spasmodic contraction of the stomach from the pyloric to the cardiac orifice, thereby emptying that organ. In order to reverse this abnormal condition and restore the electric equilibrium, he places his patient in a horizontal position, uncovers the stomach, and applies to the skin, immediately over it, a solution of sulphate of atropine in the proportion of one grain to an ounce of water; he then places the negative pole of a galvanic battery, terminating in a flat disk, upon the stomach corresponding to the pyloric region. Then, with the positive pole terminating in a moist sponge, he manipulates across the surface of the skin from the cardiac to the pyloric orifice. These manipulations are kept up for three or four minutes, occasionally varying them by vertical passes downward. During the transit of the positive pole across the surface, the muscles can be seen to contract vigorously. The stimulus of galvanism rendered to the stomach by these means is much the same as that given to any other paralyzed or weakened muscle of the body; certainly the effect produced justifies the theory. It appears to be not only local in its influence, but pervading; the whole system seems to be brought under its control; its effects are soothing and refreshing, and generally accompanied with drowsiness, followed by refreshing sleep.

Dr. Le Coniat has been practising and improving his new remedy for about three years past; he has written one or two minor articles on the subject which have been published in some of the French journals. On his return home, he proposes to publish a treatise on the subject, for the benefit of science.

Sulphurous acid is strongly recommended by Dr. Lawson in the treatment of pyrosis. It may be given in doses of from ʒss. to ʒj., in some bitter infusion, three times daily, shortly before meals.

There are on earth 1,000,000,000 of inhabitants. Of these 33,333,333 die every year; 7,780 every hour, and 60 every minute — or one in every second. But there are always more births than deaths, and so population increases.

COMFORT.

The great aim of the mass of mankind is, to get money enough ahead to make them "comfortable;" and yet a moment's reflection will convince us that money will never purchase "comfort," only the means of it. A man may be "comfortable" without a dollar; but to be so, he must have the right disposition; that is, a heart and a head in the right place. There are some persons who are lively, and cheerful, and good-natured, kind and forbearing in a state of poverty which leans upon the toil of to-day for to-night's supper, and the morning's breakfast. Such a disposition would exhibit the same loving qualities in a palace or on a throne

Every day we meet with persons who in their families are cross, ill-natured, dissatisfied, finding fault with everybody and everything, whose first greeting in the breakfast-room is a complaint, whose conversation seldom fails to end in an enumeration of difficulties and hardships, whose last word at night is an angry growl. If you can get such persons to reason on the subject, they will acknowledge that there is some "want" at the bottom of it; the "want" of a better house, a finer dress, a more handsome equipage, a more dutiful child, a more provident husband, a more cleanly, or systematic, or domestic wife. At one time it is a "wretched cook," which stands between them and the sun; or a lazy house-servant, or an impertinent carriage-driver. The "want" of more money than Providence has thought proper to bestow, will be found to embrace all these things. Such persons may feel assured that *people who cannot make themselves really comfortable in any one set of ordinary circumstances, would not be so under any other.* A man who has a canker eating out his heart, will carry it with him wherever he goes; and if it be a spiritual canker, whether of envy, habitual discontent, unbridled ill-nature, it would go with the gold, and rust out all its brightness. Whatever a man is to-day with a last dollar, he will be radically, essentially, to-morrow with a million, unless the heart is changed. Stop, reader; that is not the whole truth, for the whole truth has something of the terrible in it. Whatever of an undesirable disposition a man has to-day without money, he will have to-morrow to an exaggerated extent, unless the heart be changed: the miser will become more miserly; the drunkard more drunken; the debauchee, more debauched; the fretful, still more complaining. Hence, the striking wisdom of the Scripture injunction that all our ambitions should begin with this: "Seek first the kingdom of God and his righteousness;" that is to say, that if you are not comfortable, not happy now, under the circumstances which surround you, and wish to be more comfortable, more happy, your first step should be to seek a change of heart, of disposition, and then the other things will follow—*without the greater wealth!* And having the moral comfort, bodily comfort, bodily health, will follow apace, to the extent of your using rational means. Bodily comfort, or health, and mental comfort have on one another the most powerful reactions; neither can be perfect without the other, at least, approximates to it; in short—*Cultivate health and a good heart;* for with these you may be "comfortable" without a farthing: without them never, though you may possess millions!—*Journal of Health.*

CARBOLIC ACID IN TREATMENT OF BOILS AND ABSCESSES.—C. J. Cleborne, M.D., U.S.N., gives (in the *Druggists' Circular*) his experience with carbolic acid in the treatment of whitlows, boils, and abscesses. Having made a free opening as soon as fluctuation could be detected, and extracted, by gentle pressure, all the pus, he either injected or swabbed out the cavity with the ordinary liquid carbolic acid of the shops, after which he applied a cold water dressing. By this treatment, further suppuration was prevented, and the wound healed so rapidly that the patient returned to duty in two or three days. In some cases, after evacuating the pus and using the acid, the edges of the wound were drawn together with isinglass plaster, and in twenty-four hours it had entirely healed.

Dr. Daney recommends the citrate of soda in diabetes, in doses of from 60 to 120 grains per day. It is converted into the carbonate, and readily enters into the circulation, causing the rapid disappearance of the disease.

CODMAN & SHURTLEFF'S

Apparatus for Local Anæsthesia and Atomization of Liquids.

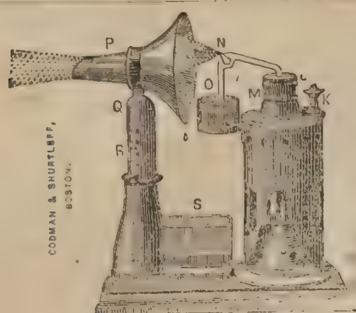

Fig. 1. U. S. Army Standard.
(Pat. March 24, 1868.)

This Steam Apparatus has been placed upon the Supply Table of the U. S. Army as the Standard.
Its joints are both screwed and soldered.
It cannot be injured by exhaustion of water, or by any steam pressure attainable.

Price $12.00.

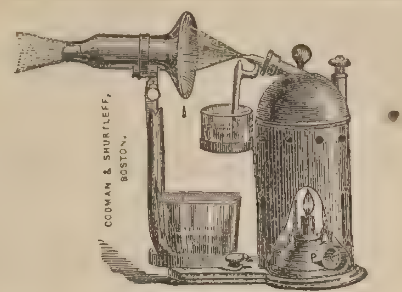

Fig. 15. The Complete Steam Atomizer (*new*).
(Patented March 24, 1868.)

All its joints are hard soldered.
It cannot be injured by exhaustion of water, or any attainable pressure.
It does not throw spirts of hot water; is convenient, durable, portable, compact, and cheap, in the best sense of the word. **Price $6.00.**
Neatly made, strong, Black Walnut Box, with convenient handle, additional **$2.50.**

Fig. 5. Shurtleff's Atomizing Apparatus.
(Patented March 24, 1868.)

The most desirable Hand Apparatus.
Rubber warranted of very best quality. Valves of hard rubber, every one carefully fitted to its seat, and work perfectly in all positions.
The Bulbs are adapted to all the Tubes made by us for Local Anæsthesia in Surgical Operations, Teeth Extraction, and for Inhalation.

Price $4.50.

Each of the above Apparatus is supplied with two carefully made annealed glass Atomizing Tubes, and accompanied with directions for use. The Steam Apparatus are tested with steam, at very high pressure. Each Apparatus is carefully packed for transportation, and warranted perfect.

ALSO,

Hand Ball Apparatus (Fig. 5, without shield), with two Glass Tubes	$4.00
Silver-Plated Tubes, for Local Anæsthesia and for Inhalation, each	2.00
Rhigolene, for Local Anæsthesia, best quality, packed	1.00
Nasal Douche, for Treating Diseases of the Nasal Cavity, six different varieties, each with two Nozzles, packed . .	$1.25, 1.50, 2,00, 2.50, and 3.50

N B.—To save collection expenses, funds should be sent with the order, either in form of draft, post-office order, or registered letter.

[For complete illustrated Price-List of Apparatus, Tubes, etc., see pamphlet.]

Will be sent by mail (post-paid) on application, a Pamphlet containing two articles, by distinguished foreign authority, on

"INHALATION OF ATOMIZED LIQUIDS."

With formulæ of those successfully employed.

Also an article by Dr. J. L. W. Thudichum, M.R.C.P., on

"A NEW MODE OF TREATING DISEASES OF THE NASAL CAVITY,"

WITH HIS FORMULÆ.

Also, an illustrated description of the *best apparatus* for the above purposes, and for producing **Local Anæsthesia** by Atomization with Ether, by the method of Dr. Richardson, of London; or with Rhigolene, as described by Dr. Henry J. Bigelow, in the *Boston Medical and Surgical Journal*, of April 19, 1866.

All our Atomizing Apparatus is made with the utmost care with view to its complete efficiency, convenience, and durability, and every one is warranted. The Steam Apparatus (Fig. 1), has been adopted into the "Supply Table" as the standard for the United States Army. A Gold Medal has lately been awarded us by the Middlesex Mechanics' Association, for Atomizing and Surgical Instruments, as will be seen from the following report, signed by a leading New-England Surgeon and Physician:

"**1503. Codman & Shurtleff, Boston, Mass. One Case Surgical Instruments and Atomizers.**

"The Committee have no hesitation in awarding for this superb exhibition the highest premium. * * * * * The various other instruments for Inhalation of Atomized Liquids, and for Local Anæsthesia, were all apparently faultless, both in design and workmanship. The exhibitors are regarded as more especially deserving of the highest token of merit for having produced nothing except of their own manufacture.—**Gold Medal.**

"(Signed) GILMAN KIMBALL, M.D., *Chairman.*"

The following is an extract from a note from Dr. Bigelow: "I have thus far found nothing better for freezing with Rhigolene than the tubes made by you after the pattern I gave you, and which I still use with your other apparatus."

Dr. J. Mason Warren says: "Your apparatus for Atomization of Liquids seems to have been carefully made, and I think it an efficient one where required for treatment of diseases of the Throat and Lungs. The apparatus for Local Anæsthesia which you made for me answers the purpose perfectly."

ALSO FOR SALE,

Cammann's Stethoscopes, Articulated	$8 00
" " Disarticulating . . .	8 50
Simple Throat Mirrors	1 50
Ophthalmoscopes, Liebreich's	7 50
Holt's Dilator	18 00
Barnes' " set of three, with Inflator . . .	7 50
Bowman's Probes, per set	4 00
Williams' Modification of do., per set	5 00
Large Ear Mirrors	$4 50 to 5 00
Hypodermic Syringes	$3 50 to 16 00
Miller's Intra-Uterine Scarificator (post-paid) . .	7 00
" " " " (in case) postpaid .	8 50
Æsthiometers	$3 50 to 5 00

Lente's Intra-Uterine Caustic Instruments .	$1 50 to $4 00
French Rubber Urinals, with valves, male, for night or day	6 00
French Rubber Urinals, male, day only . . .	4 00
" " " female, "	3 00
Vaccinators, Automatic, in case, postpaid . . .	4 00
Laryngoscopes, complete	$18 00 to 28 00
Dr. Oliver's Laryngoscopic Lantern	4 00
" " " " with Auto-Laryngoscopic Attachment	5 00
Dr. Oliver's Laryngoscopic Lantern, with Auto-Laryngoscopic Attachment, and three Laryngoscopic Mirrors, in case	10 00

Trusses, Spinal and Abdominal Supporters, Shoulder Braces, Suspensory Bandages, Elastic Hose, Medicine Trunks and Pocket Medicine Cases, Otoscopes, Endoscopes, Dr. Sayre's Splints for Hip-Joint Disease, Fever Thermometers, Respirators, Syringes, Crutches, Universal Syringes, Galvanic Batteries and Apparatus, Uterine Sponge Tents, French Conical and Olive-tipped Bougies and Catheters.

Skeletons, Skulls, Manikins, Anatomical and Pathological Models and Charts on hand, or imported to order. Prices on application. All Instruments, Implements, and Materials used by Dentists, always on hand. Apparatus for Club Feet, Weak Ankles, Bow Legs, Spinal Curvature, and other deformities, made to order. Instruments made to order, sharpened, polished, and repaired.

CODMAN & SHURTLEFF, Makers of Surgical and Dental Instruments,

13 & 15 TREMONT STREET, BOSTON.

WINE OF WILD CHERRY BARK.

(*Prunus Virginiana, or Cerasus Serotina.*)

"The bark of the wild cherry is among the most valuable of American remedies. Uniting with a tonic power the property of calming irritation and diminishing nervous excitability, it is admirably adapted to the treatment of diseases in which debility of the stomach, or of the system, is united with general or local irritation."

For the information of physicians, we give a general statement of our method of producing Wine of Wild Cherry Bark. The best bark is selected, reduced, and exhausted of all its properties, without the aid of heat. The result is a liquid in which resides in a latent condition the sedative principle, and this is developed only by bringing the amygdalin of the bark, which hides this principle, into contact with emulsin: this reaction liberates hydrocyanic acid, which thenceforth constitutes one of the most active and valuable principles of our preparation. Sound sherry wine is then added in such proportion as to act as an adjuvant to the combined virtues of the drug.

The remarkable sedative properties of this bark are in this preparation fully developed, and constitute, with the tonic bitter, a very efficacious and palatable remedy. Physicians who prescribe "Wine of Wild Cherry Bark" should be particular to obtain that preparation which combines all the virtues of the drug. Prepared by

H. & J. BREWER,

263 MAIN STREET, SPRINGFIELD, MASS.

Liquid Permanganate of Potash.

For cleaning and making sweet, musty or bad-smelling Casks or Vats, used for holding Cider, Beer, etc.

It is well known that Cider, Beer, Wine, Vinegar, etc., no matter how good, are spoiled by being put into foul or musty casks.

Permanganate of Potash is one of the most powerful purifying and deodorizing agents known, immediately destroying most organic substances brought into contact with it; and it possesses the advantage over all other disinfectants of being perfectly harmless and inodorous, at present being largely used for the purification of water.

These qualities have led us to apply it for the purpose mentioned. The great success which has attended its use up to the present, gives us confidence in recommending it to the trade generally, knowing that in practice it is perfectly suitable for the purpose; and casks treated with it do not affect cider, beer, or other beverages in any way. To brewers and cider-makers who know the difficulty of *curing* musty casks, the Permanganate of Potash will prove of great advantage. Its action is so rapid that the most foul cask is rendered perfectly sweet in a few minutes.

It can also be used for the *prevention* of must, and the system of treating every cask with a small quantity of Permanganate before being filled is at present employed with great advantage.

☞ The contents of each bottle is sufficient to cleanse four casks of thirty-six gallons each.

Directions for Use.—Put into a barrel of thirty-six gallons, previously well cleaned, one quarter the contents of the bottle, mixed with about one gallon of boiling water; turn it round immediately, so as to bring the liquid into contact with every part of the sides and ends, then fill up with cold water and let stand for a short time; when the liquid loses the last trace of a pink color, and becomes brown, the work is finished.

Price per bottle, 75 *cents.*

PREPARED BY

JAMES R. NICHOLS & CO., CHEMISTS,
150 Congress Street, Boston.

Citrate of Iron and Manganese.

(SOLUBLE.)

Contains,—	Citrate of iron	75 parts.
	Citrate manganese...........	25 parts.
		100

Dose.—Six or eight grains to adults, dissolved in water, syrup, or wine.

J. R. NICHOLS & CO., Manufacturing Chemists,
150 Congress Street, Boston.

PLATINUM APPARATUS, SHEET, WIRE, etc, for all Laboratory and Manufacturing purposes. Platinum scrap and ore purchased.
H. M. RAYNOR,
Office, No. 748 Broadway, N.Y.

A FEW STUDENTS will be taken for practical instruction at the office of DRS. QUERNER & BOOTHBY,
315 Girard Avenue, Philadelphia, Pa.

FOR SALE—A SPLENDID PROPERTY, with a GOOD MEDICAL PRACTICE, if applied for soon. If preferred, will dispose of Practice alone. For particulars, address,
"PHYSICIAN," Trenton P.O., N.J.

BOSTON DRUG MILLS, No. 90 North Street, Boston. Drugs, Dye-Stuffs, Chemicals, Crude Substances, etc., cleaned, bruised, crushed, ground, powdered, bolted, or dusted, by careful and experienced millers.

Our wagons will call for goods in any part of the city, on receipt of order. J. C. PIERCE, Agent.
E. C. Pierce, Secretary.

FISH GUANO for sale by J. M. Lincoln & Son, 140 Commercial Street, Boston.

TO PHYSICIANS.—Prof. Horatio R. Storer will deliver his FOURTH PRIVATE COURSE of TWELVE LECTURES on the Treatment of the Surgical Diseases of Women, during the first fortnight of December, with illustrative operative instruction at the Franciscan Hospital for Women, under his charge.

Fee $50, and Diploma required to be shown. Certificates of attendance upon the previous courses have now been issued to twenty-nine gentlemen in different parts of the country.

Hotel Pelham, Boston, September, 1868.

FOR SALE CHEAP—A Physician's Practice, with house, lot, and fixtures, within an hour's ride by railroad from Buffalo. Reasons—wish to go West. For particulars, address
E. W. MARSH, M.D., Darien, N.Y.

Familiar Science.

OUR LITTLE SUNS.

Those vast masses of matter called planets, in obedience to great natural laws, revolve around the sun, and their dark surfaces are lighted up by his effulgent beams. During one half the hours we are permitted to spend upon our planet, he leaves us in shadow, and it becomes necessary that we should devise some *little suns* to imperfectly compensate for his absent rays. Our forefathers used rushlights and tallow candles; in more modern times the rich "harvests of the sea" supplied oil, and the simple devices of the primitive people of olden times, were in a measure cast aside and forgotten. Then, we began to bore great auger-holes into the bosom of mother earth; down, down, through sand, clay, and rocks, the sharp revolving instruments were thrust, and upon their return, a strange black liquid bubbled up; this we call oil, and by its combustion millions of very excellent little suns are produced, about which scores of happy families revolve every evening.

But we have to speak in this writing more particularly of that class of artificial suns which the learned and ingenious chemists have suggested or devised, and which have more recently attracted the world's attention. We will allude to them very briefly: First, we have the *electric light*. Of these devices there are many, all dependent upon the agency of electricity for obtaining results. As a class, they are more or less imperfect, the main obstacles in the way of complete success being the cost of production, and some mechanical difficulties comparatively unimportant. A score of indefatigable, laborious students, in various parts of the world, are hard at work upon the important scientific problem of the production of a cheap and practicable light by the use of the electrical forces, and it indeed furnishes a promising field for labor and research. Moses E. Farmer, of this city, one of the most intelligent and indefatigable experimenters in the country, has devoted several years to this special department of study, and the results are exceedingly interesting and important. He is not yet ready to report progress, but this much we venture to say: a very confident expectation may be indulged, that before many months pass away, a cheap, practicable electric light will be ready to dispute with gas and kerosene a place in our workshops and dwellings.

What is known as the *zirconia* light is attracting some attention in Europe. It presents no claims worthy the attention of housekeepers, inasmuch as it is a simple substitution of the rare earth zirconia, for lime, or magnesia, in what is known as the Drummond light. It requires for its ignition, a mingled stream of oxygen and hydrogen, and this renders its use impracticable for ordinary purposes. The new metal *magnesium*, as is well known, affords a most intense light when it is formed into thin ribbons and burned. One serious objection to its general employment—that of cost—has been recently removed, by the discovery of a new and wonderfully cheap method of producing it. Another still remains, and that relates to the production of clouds of impalpable magnesia dust, formed during combustion, which is precipitated upon furniture and renders it unpleasant and injurious. Undoubtedly some lucky experimenter will soon devise a lamp capable of taking care of the magnesia as it is formed, depositing it in some receptacle, and thus enable consumers to secure and sell it to the druggists as medicine. We entertain strong expectations that some practical good will flow from the light produced by burning magnesium.

The recent discovery by which oxygen is very cheaply isolated from atmospheric air, has an important bearing upon the subject of artificial illumination. A full supply of oxygen to flame proceeding from ignited hydrocarbon bodies, increases the luminosity in a wonderful degree. We secure in our gas-lights but about one half the illuminating power which should result, and which would result, if *perfect combustion* took place. Our atmospheric oxygen, by which alone any combustion or luminosity is obtained, is largely diluted with that dead, negative element, nitrogen. This prevents a full supply of oxygen entering into combination with the carbon of the gas, and developing its higher luminous capabilities. Now, if we get rid of the nitrogen, and by artificial contrivances are able to pour a stream of pure oxygen into the jet, we very nearly double its power, and consequently we need not consume but half as much. Here is a cheapening process, provided we can obtain the oxygen at cheaper rates than the carburetted hydrogen or street gas.

We have heretofore described in the *Journal*, Tessié du Môtay's new method of producing oxygen. He procures it from the atmosphere, by first combining it with manganese and soda, and then expelling it from these bodies. The same quantity of manganese and soda will answer for an indefinite amount of oxygen. It is an ingenious but simple process, and the wonder is, that it was not suggested before. The powerful agent is thus furnished in great quantities at a low cost, and it is easy to see that it must have an important bearing, not only upon the matter of artificial illumination, but upon many industrial processes.

The *air light*, so called, is formed by making atmospheric air the vehicle for the conveyance of hydrocarbon vapors, as that of benzole, or light naphtha to burners. All the dozen or more "atmospheric," "gasolene," "automatic," "liquid gas" machines involve this simple idea, and nothing more. We may rightfully be regarded as the parent of the whole of them as a class, as twenty years ago we published the results of our experiments in this direction, as the readers of the *Journal* very well understand. We shall hear but little regarding these devices ten years from the present time. They are open to many objections.

We must exercise considerable patience in this matter

of devising "little suns" for our health and comfort. We are manifestly on the borders of that field of discovery from which the most desirable and important results are to be realized. The chemist is pushing his way in that direction, passing long days and sleepless nights that he may bring immortality upon himself and confer a blessing upon the race.

RANSOME'S ARTIFICIAL STONE.

Success is the touchstone with which we try every thing. But while we applaud the man who attains it at a single leap, how much more worthy of our praise is he who has accomplished his ends only by the long-continued exercise of steady perseverance and determination! It is always pleasant to record instances of such well-deserved success, and in the one that is the subject of this article, we have just such an instance, some account of which will we think interest our readers.

In 1844, an Englishman, Mr. Ransome, conceived the idea that, by making use of certain chemical reactions, he would be able to manufacture artificial stone on a large scale and very cheaply. After seventeen years of labor, he finally attained his end; and for several years past his processes have been in practical operation, at the works of the Patent Concrete Stone Company, at East Greenwich, England. His method consists essentially in binding particles of sand together, by means of a cement of silicate of lime. This is done by mixing with the sand, a strong viscid solution of silicate of soda and then treating the mixture with a solution of chloride of calcium; double decomposition takes place between the two salts; silicate of lime and chloride of sodium are formed, the the mass hardening as the reaction goes on. The chloride of sodium being washed out, there remains a solid, stony mass that retains the shape that was given to the pasty mixture of sand and silicate of soda. This seems very simple, but Mr. Ransome found difficulties enough in carrying it out. He had first to find out a cheap way of making silicate of soda, which was then prepared either by fusing silica with caustic or carbonated soda, or by boiling calcined, powdered flints with solution of caustic soda. The latter gives a weak, very alkaline solution; and both were too costly. He at last hit upon the plan of dissolving his flints in boiling caustic soda, *under pressure*, and found it perfectly successful; indeed it was not even necessary to powder the flints. At the works of the company above mentioned, the solution is prepared in a cylindrical iron boiler under a pressure of 60 or 70 pounds to the square inch. The flints are placed upon a grating, solution of caustic soda of sp. gr. 1.12 poured in, and steam turned on. After the flints have dissolved the liquid (sp. gr. 1.2) is drawn off into a settling tank, whence the clear liquid is run into an evaporator and concentrated to sp. gr. 1.7. We have now a thick, gummy, transparent fluid ready for service. The sand is prepared by drying it in an inclined revolving cylinder, through which a stream of hot air is passed; it is then sifted and a portion of it powdered under cast-iron edge runners. The sand in its natural state would make a stone of too coarse a grain; some powdered sand is therefore mixed with it, and sometimes a little powdered limestone is added. The sand mixture and silicate in the proportion of 2½ to 3 bushels of the former to 1 gallon of the latter, are placed in a mill and thoroughly mixed together. The pasty mass from the mill has just sufficient coherence for moulding purposes.

The moulding is an operation requiring considerable care, as every portion of the mould must be completely filled. The pieces after removal from the mould are sprinkled with a solution of chloride of calcium, and soon become hard enough to bear moving about. It is, however, necessary that every part of the incipient stone should be saturated with the lime solution, and this is accomplished in an extremely ingenious manner. During the process of moulding, an opening is made leading into the centre of the piece and when the solution of chloride of calcium is applied, a pipe is put into this opening and the air exhausted; the pressure of the atmosphere upon the outside forces the liquid completely through the mass. Or if the piece has been moulded solid, it is placed in a box with a perforated false bottom, and exhaustion made from beneath with equally good effect. The objects are now boiled for several hours in the same solution, in order to make it certain that the action is complete. It is very likely too, that the boiling has a tendency to harden the cementing material. The only things now left to be done, are to wash out the chloride of sodium formed in the stone, by the reaction of the chloride of calcium upon the silicate of soda, and to dry the finished articles. The washing is accomplished at the East Greenwich works in shower-baths, supplied with a continual stream of water; any excess of chloride of calcium is, of course, removed at the same time. When the season permits, drying in the sun is preferred; at other times artificial heat is used. It is very evident, that this process is capable of very extended application. Articles of any shape can be made by it, from the plain, square block to the most elaborate and highly ornamented capital. It is peculiarly adapted to the manufacture of mantels, balustrades, or screens. The East Greenwich Company has already gained quite a reputation for such articles. They have made some ornamental screens for the India Office, in London; a number of Ionic capitals for the post-office at New Zealand; and others modelled from some of the masterpieces of Grecian art, intended for buildings at Calcutta. They make grindstones of unequalled uniformity, and, in fact, do any kind of stonework expeditiously and cheaply. It might safely be predicted that this stone would stand the test of time; and such has been the case, wherever it has been tried. From its composition, and especially from its uniformity of composition, we can be certain that it is of an enduring nature. Ransome's process will be of especial value in localities where building material is not found, and even in many places where natural stone abounds, the cost of working it will be so great that the artificial article can successfully compete with it. Works have been already commenced in India and will soon be started in other countries. Would not this process be useful along the line of the Pacific Railroad? In the places along its line where building-stone is to be had, the skilled labor necessary to work it cannot be obtained for a long time to come; while if stone according to Ransome is made, the crude materials transported by the railroad can be worked up anywhere, by ordinary labor, to a building material better than limestone and as good as granite.

Greek Fire.—The nature of the composition used by the ancients called Greek fire, is not well understood. We make an inextinguishable flame by dissolving phosphorus, or sulphur and phosphorus, in bi sulphide of carbon. This we believe to be a more formidable incendiary agent than anything used by the old warriors of Greece. Water does not extinguish it, but wet sand or sawdnst will. Upon the removal of sand, even after many hours, it is liable to spontaneously ignite, and do much mischief. It is a dangerous agent to experiment with.

Arts.

HOW LIQUORS ARE MADE.

We present to the readers of the *Journal* some *very private* recipes for making factitious liquors, used by extensive dealers in Europe and in this country. The spirits made after these formulæ simulate the genuine most wonderfully, and are calculated to deceive even expert tasters. This exposure of the secrets of the trade cannot fail to have an influence in arresting liquor-drinking, more effective than all the oratory of temperance lecturers, combined with tracts and pledges.

RECIPE NO. 1, FOR BRANDY, FROM OIL COGNAC.—AMBER.

Oil cognac	1 ounce.
" bitter almonds	¾ dram.
" wine ethereal	4 ounces.

Being cut in one quart of spirits of wine 95°, place the whole in a bottle properly corked, and shake well together, so that the ingredients may be thoroughly dissolved. Then leave the mixture to stand for a day in a place not too cold. After this, pour the whole into about 175 gallons of pure spirits 10° to 25° above proof. Add 4 to 5 pounds sugar dissolved in water, boiled and skimmed, and as much burnt sugar as is requisite to give the brandy a handsome color. This is now to be well shaken for four days, several times each day, and suffered to remain quietly for from 14 to 20 days—the longer, the better. If it be intended to produce a fine brandy, add to the above 10 bottles of good Malaga wine, in which case, however, only 3 pounds diluted sugar are used.

RECIPE NO. 2, FROM OIL COGNAC.—WHITE.

Oil cognac	1 ounce.
Acetic ether	1 pound.
Tamarinds	4 pounds.
Cherry juice, sour	6 pints.
Sugar, dissolved in water	2 pounds.

Are cut in one gallon of 95° spirits of wine, and the ingredients then dissolved in 130 gallons of spirits 10° to 20°. Color with French coloring, and allow the liquid to stand, after having been well shaken, as long as possible.

RECIPE NO. 3, FROM OIL COGNAC.—GREEN.

Oil cognac	1 ounce.
" ethereal (of wine)	4 ounces.
" bitter almonds	½ dram.
Fleurs de sureau (elder-flowers)	3 pounds.
Tannin	½ ounce.

Are dissolved in one gallon spirits of wine 95°, and the whole poured into about 150 gallons pure spirits, of from 15° to 25° above proof. Burnt sugar is used to obtain a pale or brown color, and the tannin gives a roughness and the appearance of age. Keep from air, and filter properly.

RECIPE NO. 4, FROM OIL COGNAC.—GREEN OR PINK.

Oil cognac	1 ounce.
Acetic ether	4 ounces.
Peach "	3 "

Are dissolved in one quart 95° alcohol. Add then to it, in a clean glass bottle, 10 quarts Rochelle brandy, or pure spirits, of 15° to 25° above proof, and let it infuse for five or six days, exposed to a *moderate* heat. Shake it four or five times a day, taking particular care to keep the bottle perfectly tight. At the end of six days, draw it off clear, and put the contents into 130 gallons pure spirits from 15° to 20°. This preparation will be found to possess a delicious bouquet or flavor.

Manufacturers will find it to their advantage to use sometimes with discretion, tamarinds, bruised French plums, wild-cherry juice, peach ether, old brown sherry, clean oak shavings, tincture catechu, finely powdered charcoal, black tea, ground rice, and other ordinary materials well known to distillers and rectifiers, each valuable for their respective properties.

RECIPE FOR GIN.

Oil angelica	1 ounce.
" juniper, triple	1 "
" rum, white	1 "
Essence lemon	4 drams.
Salt, culinary, dissolved in water	2 pounds.
Syrup, white sugar	1½ galls.
Water	5 "

These ingredients are to be dissolved in about two gallons of high proof alcohol 95°, and after being thoroughly united, poured into about 100 gallons of spirits of

wine, of from 10° to 15° above proof. Distillers frequently employ oil caraway ½ ounce, oil fennel ½ ounce, and oil peach ½ ounce, each of which produces an aromatic effect, and gives a *smoothness, richness, creaminess* to the liquor. Creosote is used with great caution, where a certain degree of *smokiness* is required; and a small quantity of caustic potash is sometimes added, to render the gin biting upon the palate. The casks and utensils employed should be perfectly clean and properly prepared, so as not to give color, as much of the value of the liquor depends on its clearness.

RECIPE FOR RUM.—JAMAICA.

Oil rum, brown	1 pound.
" pimento	1 ounce.
Acetic ether	1 "
Sugar candy, crushed and dissolved in water	3 pounds.
Water, fresh and clear	10 galls.

Are dissolved, the oils being cut in high proof alcohol, in about 100 gallons of pure spirits 10° to 15°, and allowed to stand from 10 to 14 days. The rum produced will be found to possess a rich and delicate flavor.

RECIPE FOR RUM.—SANTA CRUZ.

Oil rum, white	1 pound.
Essence lemon	2 ounces.
Nitrous ether	4 "
Syrup, white sugar	1 gallon.
Water	10 galls.

The method of preparing these ingredients is the same as that observed for the Jamaica brand, care being taken to avoid an excess of any one flavoring.

RECIPE FOR PEACH BRANDY.

Oil peach, or peach ether	1 pound.
" grape	½ ounce.
Orange-flower water	½ "
Syrup	1 gallon.
Water	1 "

Are cut and dissolved in about 60 gallons pure spirits, and then allowed to stand 14 to 20 days.

The recipes here given are some of the most reliable, obtained from different European manufacturers.

It will be observed, that the GIN is peculiarly a delectable compound, with or without the "biting" caustic potash, or *smoky* creosote. The oil of bitter almonds, ethereal wine, peach extract, nitrous ether, etc., etc., are all poisons, and, when taken into the stomach with alcohol, are calculated to make "short work" with those who swallow the liquids. These liquors are often sold at the fashionable and first-class bars, and find their way into the stomachs of the most fastidious tipplers.

To Obscure Window Panes.—If one ounce of powdered gum tragacanth, in the white of six eggs, well beaten, be applied to a window, it will prevent the rays of the sun from penetrating.

To Imitate Rosewood.—Take half a pound of red sanders and the same weight of logwood and boil them in one gallon of water for one hour, then strain the liquor through a cloth and add half an ounce of alum, in powder, and stir until it is dissolved. This stain is now to be applied hot to the wood with a sponge, and it makes the reddish tinge of rosewood. When dry, the dark stain for the blackish streaks is made with a liquid obtained by boiling one pound of logwood for an hour in the same quantity of water as the above, and using it in the same manner. The dark stain can be made jet-black by adding a quarter of an ounce of copperas to the pure logwood stain.

How to Make Ivory Soft and Ductile.—According to the process of Geisler, in Switzerland, articles of ivory are placed in a solution of phosphoric acid of 1.13 specific gravity, and left there until they assume a transparent aspect. After this, they are taken from the acid, washed off in water, and dried with soft linen cloth. The articles are now as soft as thick leather; they become hard in the open air, and when placed in warm water they assume their former softness.

The application of such ivory for nipples of nursing-bottles, or for covers of sore breasts, and for similar articles, is of importance. The change evidently consists in a solution of a portion of the lime producing a composition containing a smaller percentage of lime than ivory. —*Dingler's Polyglot Journal.*

FOOD AND ITS ADULTERATIONS.

High prices for food lead to the introduction of injurious substitutes and adulteration. At the present time an unusual number of articles of food in daily use are badly adulterated. Common scandal for years has assigned to the milk vended from the wagons a reputation by no means creditable to the salesmen. Whiting, flour, water, and many other things have been found to constitute the ingredients of the produce which confiding persons have supposed to be elaborated by the mammary glands of the cow. Cream is a mythical affair altogether.

Butter has also been found to be extensively adulterated in England. About fifteen years ago the owners of the London *Lancet* employed Arthur Hill, Hassel, and others, to investigate the matter of the adulteration of food, and published the results of their experiments in a series of papers. The scales and test-tubes were employed in the endeavors to determine the quality and ingredients of the various staple articles employed in diet by the inhabitants of the British metropolis. Dr. Hassel afterward embodied the results of his labors in a volume, which is declared to be a very cyclopedia of dishonesty. No less than forty-eight samples of butter were examined by these investigators, and their discoveries were recorded at full length. They ascertained that about one fifth of the whole weight consisted of salt and water, the water having been stirred up with the butter rendered half fluid by heating. Potato flour was also detected.

The adulteration of coffee is more notorious. Chiccory and dandelion are commonly mingled with it; and, indeed, peas, barley, sweet corn, wheat, are substituted in its place. Even the chiccory itself is too valuable to escape analogous treatment. Doctor Hassel and his associates examined thirty-four samples of the prepared sort, and found carrot, parsnip, beet, beans, acorns, roasted corn, biscuit powder, and burnt sugar.

These gentlemen examined forty-two specimens of coffee, finding thirty-one to be adulterated purely with chiccory; twelve, chiccory and roasted corn; one with beans, and one with potato flour. A packet of "Jamaica coffee" was found to be composed almost entirely of chiccory; the "finest Java coffee" consisted of half coffee, much roasted corn, and a little chiccory; "superb coffee" was principally chiccory and roasted corn; "fine Plantation Ceylon" was almost entirely chiccory; "fine Java" was heavily charged with chiccory and potato; "delicious drinking coffee" was chiccory and roasted corn. The more imposing the name, the grosser the counterfeit appears to have been. We remember some months since to have been presented with a sample of made coffee, the flavor of which greatly resembled that of charred wool, and its effect upon the stomach was any thing but agreeable. Indeed, in this country, as well as elsewhere, there are but two certain plans to follow to obtain real coffee: to witness the grinding of it or to purchase it whole and grind it at home. Nevertheless, there are honest coffee-merchants occasionally.

The same remark applies with equal justice to the trickery played upon tea. The Chinese adulterate it themselves before selling it to the "outside barbarians," by mixing with it ash or palm leaves. The English are large in the practice of gathering the "grounds" or exhausted leaves, mixing them with a solution of gum and drying them; after which, by adding rose-pink and black lead to "face" them, they are made into black tea, and by using copperas they have green tea. The leaves of the beech, elm, chestnut, plane, oak, willow, poplar, hawthorn, sumach, holly, sloe, are used more or less in the work of adulteration. Black tea, however, does not appear to suffer much in reputation in this manner; but of green teas this cannot be said. Of course, it is not necessary to remark that the difference between genuine green and black teas consists in the peculiar manipulation given them by the Chinese.

Chocolate has also become notorious by reason of its adulterations. Flour appears to be the principal ingredient employed for this purpose; starch, sugar, cocoa-nut oil, lard, tallow, sweet ochre, and chalk, have also been used. The very mode of preparing it affords facilities which the dishonest could not leave alone. The proclivity is unfortunate, for the beverage is cheaper and more wholesome than its rivals.

The corruptions of sugar are less numerous, and are confined principally to confectionery. Gamboge, starch, flour, pipe-clay, plaster of Paris, chalk, and even copper, lead, and mercury, are used in the preparation of cheap candles.

Wheat flour is generally sold in this country in a pure condition, owing to its cheapness. But in England, it has been found upon analysis to yield such queer constituents as white corn meal, potato flour, plaster of Paris, ground bones, chalk, rye, bean, pea, and rice flour. Bread, however, is badly adulterated. There is some reason for our people to adopt the suggestion of the French tiger Marat, and hang up the bakers at their own doors. The bread which they serve becomes thoroughly unpalatable when but a few hours old, owing to the improper ingredients employed in its preparation. Alum, either pure or mixed with salt, is a familiar article in the manufacture, making inferior flour white, and enabling it to absorb a larger quantity of water.

The remedy for these evils is an important topic for consideration. Legislation has often been proposed, but we cannot quite agree with those who regard it as the panacea of human ills. Indeed, it is hardly possible to establish in any large community, like Boston, New York, or Philadelphia, a system by which unwholesome or adulterated articles would be excluded from the market. Beside, we are a people jealous of much governing. We prefer to be cheated in the weight or quality of our bread, the quantity of our berries, the constituents of our milk, or even the ingredients which constitute our coffee or wine, to the alternative of an espionage into our habits and employment. The surveillance which in many European countries exposes every man's most trivial acts to the cognizance of government, would be resented by us as an unpardonable outrage on personal rights. We prefer to take our chances with the petty knaveries of our neighbors, to hourly contact with the informer, the policeman, or the magistrate.

Color Blindness, or Daltonism.—Persons affected with the erroneous perception of colors are partially unfitted for many occupations; but there are some professions in which the defect is a source of positive danger. Some railroad accidents have been reported from this cause; and on the French lines many candidates are rejected on account of their inability to distinguish a green from a red light.

Cleaning Silk.—The following is said to be an excellent recipe for cleaning silks:—Pare three Irish potatoes; cut them into thin slices and wash them well. Pour on them a half pint of boiling water, and let it stand till cold; strain the water and add to it an equal quantity of alcohol. Sponge the silk on the right side, and when half dry, iron it on the wrong side. The most delicate-colored silk may be cleaned by this process, which is equally applicable to cloth, velvet or crape.

Mode of Dividing Glass.—The following plan, to break a bottle or jar across its circumference, so as to form a battery cup, or vessel for other purposes, may be of some service to your readers. I have performed the operation successfully many times. Place the bottle in a vessel of water, to the height where it is designed to break it; also, fill the bottle to the same level. Now pour coal-oil, inside and out, on the water; cut a ring of paper, fitting the bottle. Saturate with alcohol or benzine, so that it touches the oil. Pour, also, some inside the bottle. Set on fire; the cold water prevents the glass from heating below its surface, while the expansion caused by the heat will break the vessel on the water line.—J. T. Peet: *Scientific American.*

Ink from Elder.—We learn from Wittstein's *Vierteljahresschrift* that an excellent permanent black ink may be made from the common elder. The bruised berries are placed in an earthern vessel and kept in a warm place for three days, and then pressed out and filtered. The filtered juice is of such an intense color that it takes 200 parts of water to reduce it to the shade of dark red wine. Add to 12½ parts of this filtered juice, one ounce of sulphate of iron and the same quantity of pyroligneous acid, and an ink is prepared which, when first used, has the color of violet, but when dry is indigo blue black. This ink is superior in some respects to that prepared with galls. It does not become thick so soon; it flows easier from the pen without gumming; and in writing, the letters do not run into one another.

GREEN PAPERS.

Editor Boston Journal of Chemistry:—

A stove furnished with one of Chilson's dampers was left burning in a bookbinder's shop on a Saturday evening. The door of the shop was closed. It was opened but once on the next day, to replenish the coal, which continued to burn till Monday morning. A pile of printed paper, designed for the covering of school-books, was lying in the shop, near the floor. The ground of the paper was green. On Monday morning, the surfaces exposed to the air of the room were found to be straw-colored instead of green.

Did the sulphurous gas from the coal accumulate to such a degree, in the closed room, as to form a sulphite of arsenic with the arsenic oxide of the paper? Is it proper to use arsenic in the covers of school-books put into the hands of children? J. R.

CONCORD, MASS.

NOTE.—The greens found upon papers are usually the arsenide of copper, and are poisonous. By the action of the coal-gases, the color was decomposed, and orpiment, or sulphide of arsenic, was formed upon the paper. All paper of a green color should be rejected by binders of books, as unsafe to use.

HEAT PHENOMENA.

Editor Boston Journal of Chemistry:—

Your correspondent's views regarding the "Phenomenon Relating to Heat," expressed in the January number of your valuable *Journal*, no doubt are correct, and agree with the views of scientific men generally. It is not difficult to prove, in more ways than one, that the effect is not due to a vibratory motion of dust. If it was, what would prevent our seeing the movement, whether the background was varied or otherwise? The conditions for changeable refraction are favorable, as the constantly varying density of the air flying away in hot currents succeeded by colder, changes the refractive power of the medium through which the objects of the background are seen; they are, therefore, necessarily tremulous and distorted. The twinkling of stars is explained in the same way; and the bad weather generally following proves that there were currents of various densities and temperatures.

Yours truly, M. B. MANWARING.

NEW BRUNSWICK, N.J., Jan. 19, 1869.

THAWING FROZEN WATER-PIPES.

Editor Boston Journal of Chemistry:—

Water-spouts and sink-spouts that are frozen up may be speedily thawed out in the following manner:—

Procure a piece of lead pipe of suitable length and size; place one end against the ice to be thawed, then, through a tunnel in the upper end, pour boiling water. Keep the pipe constantly against the ice, and you can penetrate one foot or more per minute.

Thinking the above would be appreciated by the readers of your always welcome and useful *Journal*, I thought proper to communicate it. WM. E. ROGERS.

REXFORD FLATS, N.Y.

COATING TIN WATER-PIPES.

Editor Boston Journal of Chemistry:—

In a conversation with Dr. Charles T. Jackson, the well-known chemist of Boston, some years ago, upon the introduction of water through lead pipes, he stated that he had employed block-tin pipes in his own house; but, as they would corrode through in six months if laid in the soil, he had had them wound around with strips of canvas well saturated with pitch, and then coated all over the outside with hard pitch about an inch thick. He stated it would preserve the pipes for years, and also serve as a protection against frost. This information may be of interest to your readers. H.

NEW CEMENT FOR TEETH.—Freshly calcined oxide of zinc, 9 parts; finely powdered borax, 1 part; finely powdered silex, 2 parts; all mixed well together. A correspondent of the *Druggist* states that this makes a firm plastic mass, and that it is used by French and German dentists.

ZODIACAL LIGHT.

DR. NICHOLS.—Dear Sir: At a meeting of the "Cincinnati Literary Club," held Jan. 2d, 1869, which was addressed by Prof. C. Abbe, Director of the Cincinnati Observatory, the speaker said:—

"Cassini first, in 1633, began to make observations of the zodiacal light; and the common explanation of its appearance has been, that it must be an ellipsoidal atmosphere about the sun. This, however, is of a different constitution from the corona above referred to, and, from the observations of Jones and Schmidt, appears to extend beyond our earth at times. We have thus the sun surrounded by an immense thin, transparent gas—the zodiacal light, within which is a denser atmosphere—the corona, within which is a luminous atmosphere—the photosphere, within which is the liquid molten lava-surface of the sun, and this doubtless incloses a solid nucleus."

Should you think proper, please insert this in the *Journal*, and oblige, NICHLOS JOHN, M.D.

CINCINNATI, Jan. 14, 1869.

REMEDY FOR FROST-BITE.

Editor of Journal of Chemistry:—

If it is the foot, tie it up in a pound of flour, covering every part well with the flour for some hours. The flour will come off quite wet; but the circulations will be restored. The next dressing with flour will come off with very little moisture; the blisters, if any, will dry up, and the foot give no further trouble, except that the toe-nails may come off; but they will grow on again. G. H.

BOSTON, Jan. 18, 1869.

Agriculture.

THE CHEMISTRY OF "SUPERPHOSPHATE."

It is no matter of surprise, that those who have not made the sciences special matters of study, should be puzzled, and even annoyed by the terms and symbols used, especially in the department of chemistry. It is difficult for chemists to write upon the subject, or attempt to explain principles, without making use of language which is imperfectly understood by a majority of readers. We have always endeavored, when writing for general readers, to write *outside* of the technicalities of the science, and forget for a while the easier methods of expressing thoughts, which can alone be understood by the student or professional man. When asked, as we often are, to explain what "superphosphate" is, chemically considered, we do not think it advisable to commence by stating the objections we entertain to the use of the term, and then resort to symbols to explain our meaning. This would be the shorter and easier way, but not the best, for the purpose had in view. "Superphosphate," or superphosphate of lime, is a mixture of gypsum, and *three* different phosphates of lime. There are no less than *thirteen* different phosphates of soda, upon the nature of which an extended treatise might be written. If plaster or gypsum, is a normal constituent of genuine superphosphate, how comes it to be present, if it is not designedly mixed? A brief consideration of what superphosphate is, or how it is made, will explain this. If we take the bones of an ox, or any other animal, and place them in the fire, they will burn, if the fire is very intense, almost as freely as a pine knot. In some bone establishments, large steam-engines are propelled by burning the bones used in the manufacture of phosphorous, or the phosphates. That which burns, is the animal portion, or the gelatine; the *ash* is bone phosphate, or phosphate of lime, which no amount of heat can destroy. Water will not dissolve it, no matter how much is used. This bone ash is composed of a peculiar acid, called phosphoric acid, and common lime, with a little magnesia and soda. Phosphoric acid is formed from that most singular, easily inflammable element, *phosphorous*, and oxygen; take away the oxygen from the phosphoric acid, which the farmer uses to fertilize his fields, and he has in his possession one of the most poisonous and dangerous elements known to chemists. The lime and the phosphorous in the bone, the animal obtained from the *grasses* and *grain* which it consumed as food; the grasses and grain obtained them from the *soil*; hence, it is easy to see, that by sowing bone-dust, or superphosphate upon our soils, we are only restoring what has been taken from it. Water will not dissolve or decompose bone ash (phosphoric acid and lime), *acids will*. Now if we mix oil of vitriol or sulphuric acid with bone earth, or ground bones, it breaks up the compound and forms new ones. Before we mix the vitriol, the phosphoric acid clings to the lime most tenaciously, but when the "*King acid*" steps in, he says to the phosphoric, "Stand aside! I will take charge of the lime atoms;" and this he does. The lime is severed from the embrace of the phosphoric acid; the sulphuric unites with it, and forms sulphate of lime or gypsum; the liquid phosphoric acid is free, and the insoluble plaster remains as a heavy precipitate. It must be understood, that dissolving bones in acid does not give a clear solution, but forms a thick pasty mass, made up largely of gypsum. No amount of acid will, however, change all the lime into gypsum; a portion of phosphate of lime remains dissolved in the free phosphoric acid, and the solution may be produced perfectly clear.

Some farmers who have dissolved bones, using the proper quantity of acid, have been afraid to use the mixture, fearing the oil of vitriol which it contained would "burn up their crops." They find the mass to be *very sour*, and hence conclude the vitriol is unchanged. This is not the case. It is the *free phosphoric acid* which gives the excessive sour taste, and this is what is wanted to make crops grow. The value of "superphosphate" mostly depends upon the amount or percentage of *soluble phosphates* it contains. The highest, purest form of the agent, is made by taking 100 lbs. of powdered calcined bones, and dissolving in 87½ lbs. of oil of vitriol; from this mixture there will result, superphosphate of lime (double) 26 lbs., gypsum 66 lbs, sulphate of magnesia 1½ lbs., sulphate of soda 2¾ lbs; if carefully made, 30 *per cent of this is soluble in water*. This would be superphosphate worth having. Do we get it in the commercial article? Never. Do we get one half, or 15 per cent? No. We have never found a specimen that contained 10 per cent. A true, carefully prepared superphosphate of lime is not on sale, so far as our observation extends. If 100 lbs. of powdered, *unburned bone* is used, 40 lbs. of acid is fully sufficient, as the amount of earthy phosphates present is very much less. We have heretofore described in the *Journal*, the process by which we prepared superphosphate upon our own farm premises. The method is a good and safe one to follow.

POULTRY AND EGGS.

A good deal of experience has taught us that success in the poultry-yard depends as much upon good general management as upon any one thing. When the eggs of any hens indifferently are kept for the purpose of raising young chickens, and when little attention is paid to the particular hens reserved for laying, it will in general be found that the profits are small, and the quality of fowls raised rapidly deteriorates.

In addition to the usual plan of selecting only the best formed and quietest hens for breeding purposes, we have found it of advantage to pay considerable attention to the age of the fowls which we retain. For the produc-

tion of eggs for domestic consumption we never keep hens beyond their second year, but for raising chickens we have found it to be poor policy to employ eggs laid by hens less than two years old. We have always found that the chickens from the older hens are more easily raised, have stronger constitutions, and turn out every way better than those raised from pullets. The eggs consequently cost more, but this extra expense is but a small item on the number of eggs usually employed for hatching.

In order to have eggs during winter, besides the usual appliances of meat, lime, sand, bones, etc., we always make sure of having some very early chickens. The pullets of these will commence to lay in October or November, and will lay throughout the winter. Next season we draft a few of the very best of these and keep them as breeders, the balance being fattened and killed off as soon as they have positively ceased laying. At this time it is wonderful how rapidly hens take on fat. We often see accounts of hens not laying because they are too fat. When considering the ease with which hens fatten as soon as they cease laying for the season, we have often thought that the true way to state the case, is, that they fattened because they did not lay. At this age they are delightfully tender and juicy, and we would about as soon think of fattening a cow that gave twenty quarts of milk a day as to think of fattening a laying hen.—*Country Gentleman.*

In the following brief essay upon manures, presented to the *Essex Agricultural Society* and published in their *Transactions* for 1868, allusion is made to a series of experiments undertaken at LAKESIDE FARM, by the author, having in view the determining of some interesting questions in agriculture. These experiments extend over a period of five years, and have been very carefully and systematically conducted. It was intended in commencing the paper, to present the results and conclusions in detail, but illness prevented. The nature and design of these experimental labors will be understood from what is presented below; and if there should be a general desire expressed to learn further regarding them, we might be led to place them in a form accessible to those interested. There is great need of careful, long-continued observation and experiment, in order to reach conclusions worthy of confidence. But little of such work has been undertaken in this country, and hence we have been compelled to look to England and Germany for our knowledge of scientific husbandry. The soil and meteorological conditions of the countries named do not correspond with those upon this side of the Atlantic; and failures and disappointments often result when the conclusions of foreign writers are put to a practical test.

MANURES—SPECIAL OR CONCENTRATED FERTILIZERS.

BY JAMES R. NICHOLS, M.D.

Nothing more readily attracts the attention of farmers, or conveys more palpable ideas of value, than *bulk*, in manurial substances, and yet nothing is more deceptive or fallacious. A huge bank of animal excrement under the eavesdroppings of the barn, has indeed a positive value, but it does not consist in the great mass of the material of which it is made up. Squeeze out the water, remove the sand and chaff, and we can place all the fertilizing elements of that heap in the smallest sized dump-cart. The high value of stable or barnyard manure, is not found in the eighty or ninety per cent of water, silica, etc., which it contains, but in the nitrogenous elements—the potash, soda, and phosphatic salts, which in amount occupy relatively a most insignificant position. And I may say further, that the exerementitious salts found in the manure heap have the highest positive value as plant-food, of any substances with which we are acquainted. They exist in a form ready to be again taken up by plants and assimilated into the living organism. They differ from the same class of agents found isolated in the hands of the chemist, inasmuch as they have had conferred upon them in their passage through vegetable and animal structures, a kind of vitalized capability, the nature of which is imperfectly understood by chemists.

But the deceptive nature of bulk in fertilizing agents, is not confined to barnyard manure. Leaves, peat, muck, chaff, etc., need to be carefully examined in order to understand their actual value to the farmer. I have been led during the present autumn to make somewhat extended analyses of these substances, with the view of testing the correctness of some published statements regarding them, and also, to learn of how much positive service they may be to the farmer. A bushel of well pressed dry leaves, as they fall from the trees in autumn, weighs about four pounds; by further drying, they part with a little more than thirty per cent of water held in the cells of the leaf structure. A cord of absolutely dry leaves will weigh about 325 lbs., reckoning one hundred bushels to the cord. In weight, then, a cord represents about one twelfth of a cord of wet barnyard manure, and if they contained the same amount of fertilizing material in the same condition, would be equal in value to that amount of manure. But this is far from being the fact. The dried leaves I have found to stand relatively to the leached organic matter of manure, as 10 to 30, in ash value; and when the soluble salts of manure are taken into account, the comparative value is as 10 to 60, weight for weight. A cord of dry forest leaves, made up of the usual deciduous varieties, maple, beach, oak, etc., has an actual *manurial* value of not over *fifty cents*, reckoning good stable manure at eight dollars the cord. Will it pay to collect them? Certainly not for the amount of fertilizing material they contain. As litter or absorbents in the stable, leaves have some value, but much less than straw, inasmuch as they lack the reedy character of straw, and because they are far more difficultly and slowly decomposed.

A pound of good, thoroughly formed peat, taken fresh from the meadow upon my farm, lost of water in drying, a little more than fourteen ounces. A farmer drawing from his meadow a cord of peat weighing 4000 lbs., has upon his wagon 3500 lbs. of water, and but 500 lbs. of the dry material he seeks. This, dried and compressed, could be placed in a couple of our largest sized farm-baskets. The amount of ash constituents in the pound of peat after drying, was a little less than 10 per cent, so that when we reduce the heavy load of peat, which to the eye appears so bulky and valuable, down to its contained inorganic principles, we find the whole amount to be less than 50 lbs. I hope not to be misunderstood in the matter. The ashes are far from being the only manurial part of peat, and as in burning some of the most valuable elements are volatilized and lost, it is not good economy to burn peat for the purpose of securing the ashes. Fresh peat allowed to ferment in contact with lime, is changed into new substances capable of nourishing plants, and where it can easily be obtained, it pays the farmer well to secure a good supply. I cannot help remarking, however, in this connection, that many of the statements made by our chemists and journal writers, regarding the value of muck or peat, are simply absurd, and are proved erroneous by practical experiment. The great value of peat after all, lies in its absorbent qualities. From the experiments and experience of a considerable number of years, I feel more inclined to urge the farmers of our county to save the *liquid excrement* of their animals, by the use of seasoned peat in their cattle stalls and manure pits, as an absorbent, than to recommend them to drag it many miles at much expense to be used by itself or in compost for fertilizing purposes.

How strangely we overlook the value of the liquid excrement of our animals! A cow under ordinary feeding furnishes in a year 20,000 lbs., of solid excrement, and about 8000 lbs. of the liquid. The comparative money value of the two is but slightly in favor of the solid. This statement has been verified as truth, over and over again. The urine of herbivorous animals holds nearly all the secretions of the body which are capable of producing the rich nitrogenous compounds, so essential as forcing or leaf-forming agents in the growth of plants. The solid holds the phosphoric acid, lime, and magnesia, which go to the seeds principally; but the liquid, holding nitrogen, potash, and soda, is needed to form the stalk and leaves. *The two forms of plant nutriment should never be separated or allowed to be wasted by neglect.* The farmer who saves all the liquids voided by his animals, doubles his manurial resources every year. Good seasoned peat is of immense service to farmers, when used as an absorbent, and the stalls for animals should be so constructed as to admit of a wide passage in the rear, with generous storage room, besides, for peat, to be used daily with the excrement.

The remarks above made, may be regarded as preliminary to some brief general statements upon another branch of the subject of fertilizers. With a proper idea of what really constitutes plant aliment, and of the physical and chemical nature of the bulky substances in general use, the inquiry very naturally arises, Why cannot the concentrated principles of such be obtained through other channels, and used more economically and directly upon our lands? An answer to this inquiry opens up the whole subject of the value and use of special or concentrated fertilizers, and this is a subject which has been so often and so fully discussed by theorists and others, that the reader will not thank me for going over the ground again. Upon no subject connected with agriculture, does a wider difference of opinion prevail; and the discussion of the subject in the usual unsatisfactory empirical way does not tend to settle disputed points, or clear away the clouds of doubt which hang around the whole matter. Experiment usually decides controverted points in matters of physical inquiry, and it is capable of reaching this end in the subject under consideration, but it must be made carefully, intelligently, and be long continued. Having entered upon a series of experiments of this nature, with the determination to make no report for at least five years, or until soils could be carried through a period long enough to observe the effects of disturbing influences, and also learn something regarding the growth of different crops, and the lasting effects of peculiar modes of treatment, I find myself at a point of time when it is proper to examine and make known results. The time and space allowed me in this essay do not admit of detailed statements, and such must be reserved for another channel of communication, if health and strength permit.

The experiments have been made upon a farm of about eighty acres, which was purchased in 1863 with the view of entering upon a course of experimental inquiry interesting to agriculturists. The question deemed most important to decide was, whether a run-down farm could or could not be brought into comparative good tilth by the employment of fertilizing agencies outside of stable and barnyard manures. The farm at the time of purchase was well suited to a trial of this kind, as it had been in administrators' hands for several years, and was consequently neglected and unproductive. The soil is varied in its character, with upland and lowland, a fine peat bog occupying a basin between the hills. A portion is silicious, another portion loamy with a clay subsoil, and still another part is rich in organic *debris*, a forest having until within a few years densely covered it. Perhaps no tract of land in our county presents a greater variety of soils, of differences of exposure, or affords the gradations from wet to dry, so desirable for fair experiment. The product at the time of purchase consisted entirely of hay—about twelve tons being produced, of indifferent quality. The crops the present year upon lands embraced in the original purchase, have been 30 tons of good hay, 100 bushels of potatoes, 25 bushels of wheat, 150 bushels of corn, 75 bushels of turnips, and one and a half tons of grapes, besides other fruits in considerable quantities. There has been a steady increase in the amount of crops each year, notwithstanding a series of most unfavorable seasons. The number of acres in tillage is not far from twenty. No stable or barnyard manures, excepting a few loads at the start, have been purchased during the five years, and the amount made upon the premises has been small; the stock consisting until within the past year of only three cows, a pig and one horse. At present the farm sustains eleven cows and heifers, three horses, a pig, and, during a part of the year, one yoke of oxen.

The fertilizing substances used (of which an accurate account has been kept, as also of crops, expenses of labor, etc.), embrace the entire range of those agents which chemistry suggests, and those which have been brought to notice through the recommendation of farmers and experimenters—bones, ashes, lime, salt, the nitrates of potassa and soda, sulphate of ammonia, carbonate

of ammonia, plaster, potashes, fish pommace, shorts, muck, horn shavings, and lastly, the refuse of the Maine lobster-factories. The methods of application and the conditions under which these have been employed, the combinations produced, present details which although extremely interesting, are too extensive to enter upon in this essay. A definite end has been kept in view—that of securing practical facts from which safe general conclusions could be reached. Of course many experiments known to be empirical have been undertaken, and the results noted. For example, a half-acre of grass-land was divided into eighteen equal parts, and eighteen different substances applied; the results were curious, but the experiment actually proved nothing, although a great difference was observable in the crops of grass. More than one half of the experiments which we find reported from year to year, are of this nature. The substances affording the highest satisfaction have been those which furnished in largest quantity and at the lowest rates, the great fundamentals of plant-food—phosphoric acid, lime, potash, nitrogen. These have been obtained from bones, ashes, potashes, fish pommace, and nitrate of soda, principally. Bones have been largely dissolved in acid, and true phosphate and superphosphate of lime made upon the farm premises. Bones ground and unground have been dissolved in the caustic lye of ashes, also in commercial potashes, and fertilizing subtances of the most prompt and satisfactory character produced. I doubt if better crops of wheat and corn have ever been produced in the county, than have resulted from the use of these agents, upon weak lands. I think it must be conceded that the results of these labors go to prove that exhausted soils can be brought and sustained in good tilth by concentrated chemical agents, at an expense considerably less than by the use of excrementitious manures at present market prices in the more densely populated parts of our country. In conclusion, I will briefly present some facts regarding a special experiment upon a measured acre of hill land, dry, and exhausted from repeated croppings. It has been continued through five consecutive years. In the autumn of 1863 it was ploughed, and in the succeeding spring dressed with 500 lbs. of pure fine bone, sown broadcast, and planted with corn, a handful of homemade superphosphate mixed with ground nitrate of soda, placed in each hill. One hundred and fifty-seven bushels of corn in the ear were taken from the field in the autumn of 1864. After the corn was removed, the land was ploughed and again dressed with 500 lbs. of a compost made up of bone-dust, ashes, and refuse saltpetre, and sowed down to winter rye. The crop was 31 bushels of nice, plump grain. The season of 1866 was exceedingly dry, and the ground became so parched that the tender grass roots were greatly injured. The crop of hay was twenty-three hundred pounds. The next season, a top-dressing of 500 lbs. of compost made of bone gelatine and muck was given it in the spring, and a crop of hay cut weighing forty-three hundred pounds. A heavy aftermath was secured this season, which was not weighed. The present season, the crop of hay reached two and a half tons, and the field appears to be in good condition for a fine product next year. Here we have what may be considered a fair experiment, which proves that without the use of animal excrement, a worn-out field may be brought to produce very generous crops—crops which pay a good return for the expense incurred. It proves that chemical unorganized agents are capable not only of supplying nutriment to plants for a single year, but for sustaining crops for a series of years. The fertilizing elements supplied for the five years cost a little less than thirty dollars. The experiment upon this field is not regarded as finished, and the crops will be noted until they are observed to falter.

Importance of Good Seed.—Careful attention must be given to the matter of selecting seed. Many of the failures to secure crops result from the old imperfect seed procured from dealers. Farmers and gardeners should raise their own seed, and thus save most provoking disappointments and failures. Much of that in the market is three, five, and even ten years old. Some packages are so mixed as to contain seeds raised during a half-dozen consecutive years. Look well to the seed you plant.

Boston Journal of Chemistry.

BOSTON, MARCH 1, 1869.

☞ Any one sending us the names of three new subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For five new subscribers we will send the Petite Microscope; for twenty-five we will send, in addition to the microscope, a copy of "Stöckhardt's Chemistry for Students," the best elementary treatise yet published; for one hundred new subscribers we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stöckhardt's Chemistry.

☞ Premiums are allowed only upon *new* subscribers, not on renewals of subscription by old subscribers.

☞ Physicians, students, clerks in drug-stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

☞ Correspondents are particularly requested to give their names in full, with their Town and State; and, in case of change of residence requiring a corresponding change in the mailing of their papers, to give not only the new address, but the old one also.

☞ Subscribers who are physicians, dentists, or apothecaries, will confer a favor by informing us of their profession, as we wish to know accurately the amount of our medical subscription list.

BACK VOLUMES OF THE JOURNAL.

We are unable to supply complete files of either Volume I. or II. of the *Journal*. Of Volume I. (originally issued bi-monthly), Nos. 1 and 2 (July and August, 1866) are now out of print. Of Volume II. (monthly), Nos. 1, 3, and 12 (July and September, 1867, and June, 1868) are also out of print. Of the remaining numbers we have a few copies left, which we will forward to our friends at the following prices: Volume I., four numbers, twenty-five cents; Volume II., nine numbors, fifty cents. We have on hand a few complete files of Volume III., as far as published. These we will send as ordered, at the rate of six cents per single copy; six copies for twenty-five cents.

ABOUT AIR FURNACES.

In the last number of the *Journal*, some observations were made regarding stoves; we purpose in this, to consider briefly the character of the furnaces in common use.

As a source of household warmth, air furnaces are very generally used in all the better class of dwellings, and we presume many families in which the *Journal* is read, are dependent upon this method of securing warmth. A large amount of ingenuity has been expended by inventors in constructing air furnaces, and almost every year a dozen new devices are thrust before the public, and their merits set forth in extravagant language. Upon a careful consideration, or examination, of the various patented devices for warming dwellings by heated air, the conclusion is reached, that but few essential improvements have been made in the apparatus, for a dozen years. Complexity of construction is no more desirable in air furnaces, than parlor stoves; and inventors have yet to learn the important truth, that the man who strips complicated machinery of its useless and interfering appendages, and brings the simple out of the complex, is the most highly honored, and reaps the richest rewards.

Air furnaces are very convenient, but they are also sometimes productive of much discomfort, and may be detrimental to health. Overheating is a source of danger, or an evil connected with furnaces, which is, perhaps, the most prominent, and one most difficult to remedy. Nine tenths of the houses in which they are used, are kept at a temperature much too elevated for either health or comfort. This is epecially true in the autumn and spring months, when the outside atmosphere is above the freezing point. The difficulty is to *regulate* the heat. Housekeepers find they consume nearly, or quite as much fuel in moderate weather, as they do in extreme cold; and they cannot avoid this, as

any important diminution in the amount supplied to the furnace, interferes with its regular working, and the fire dies away, or is extinguished, provokingly often. The difficulty of too much heat can be only in part remedied, and this not so much by interfering with the fire, as by regulating the flow of cool air from outside, through the furnace. A capacious air-conductor is indispensable in connection with furnaces. It should be double the size actually needed in cold weather, and the cut-off, or valve, should be within easy reach, so that it can be opened or closed, as the temperature rises or falls outside. A full volume of sweet, pure air, should flow into the dwelling in moderate weather; a volume so great that it will not become unduly heated by contact with the radiating surfaces of the furnace. Two cubic feet of air at the temperature of 50° F. contains but little more oxygen, or vitalizing power, than a single foot at the temperature of zero. One foot flowing through in January, is, therefore, equal to two feet in March or April.

The evaporation of large quantities of water in furnaces, is not advantageous or desirable. The normal moisture of the air itself is fully sufficient for health or comfort. If furnaces are properly constructed and managed, evaporating pans holding water should never be placed inside of them. The prevailing idea of the healthfulness or necessity of evaporating water in rooms, by means of stoves or furnaces, is founded in error, and is a practice that should be abandoned.

The escape of the gaseous products of combustion through the joints, cracks, and probably through the cast-iron itself, is an evil of prodigious magnitude. Chemical tests applied to the air of rooms heated by furnaces, prove sulphurous acid and carbonic acid to be almost constantly present in a majority of dwellings. In this direction one of the greatest objections to furnaces is found; and it is an evil which urgently demands attention. The utmost care should be bestowed by manufacturers upon their construction; the fewest joints allowed, and these well luted with indestructible cement. A cement made of asbestos, which no amount of heat can decompose or change, must be employed. No *damper* should ever be placed in the flue; it is one of the most dangerous appendages which can be attached to the apparatus. If by accident it becomes partly or wholly closed in the night-time (and we have known strong gusts of wind to turn them), death, or permanent injury may result to a whole household. In one instance, the father and mother of a family, in our own neighborhood, were found dead in their beds, having died from asphyxia, caused by gases proceeding from a furnace with a closed damper, in the cellar.

How iron can be made impermeable to gases, is a problem difficult to solve. If, as is alleged, *wrought iron* is free from the liability, then we must insist upon manufacturers rejecting the use of cast-iron in every part of their work.

Portable furnaces, or those constructed wholly of metal, are in common use, and we have found in quite a number of instances, that they were used without air conductors; the warm air flowing into the rooms being supplied from the cellar. Aside from the manifest unhealthfulness of breathing the often impure air from that locality, how untidy is this practice! The dust and ashes inseparable from furnaces, are taken up with the heated air, and diffused through the rooms, greatly to the injury of furniture and lungs. No furnace should ever be used which does not obtain its air current from outside the dwelling. There is commendable caution in taking down furnaces the latter part of the winter, and removing all accumulations of ashes and cinders, that there may be no obstructions to draft during the mild weather of the spring months. Ascensional currents of warm gases passing through flues, move very slow during the still, damp days in March and April, and if slight impediments to their flow are permitted in their proper channels, they escape into the dwelling. The law of gaseous diffusion is not only a curious, but an inflexible law. Poisonous gases escaping into a cellar or basement, are just as dangerous as if they flowed directly into the parlor. When free, they move in all directions, downwards as well as upwards; and no partitions, or walls, such as are found in dwellings, offer the slightest impediment to their diffusion. Therefore, the grave error must not prevail, that gases escaping into the cellar can do no harm. Equally as great care must be exercised in regard to stoves and furnaces in remote quarters, as in those used in rooms constantly occupied.

There are many other points connected with furnaces and their management, to which we would like to call attention, but these remarks are already sufficiently extended. The points brought to notice, are such as all will do well to heed, as thereby much suffering and many evils may be avoided.

SAFETY LAMPS.

Extracts from newspapers and advertisements relating to so-called "safety lamps," for burning cheap kerosene or benzine, have been frequently sent to us, with the request that we would express an opinion regarding them. We remark, in brief, that no lamp can be constructed in which these highly inflammable liquids may be used with safety. The "escape-valves" and "side-tubes" usually employed are of no service whatever in connection with lamps. They do not in the slightest degree insure safety. *Benzine is dangerous to harbor in families.* More deaths are caused by *breaking lamps* than by explosions. Very few lamps really explode. Men, women, and children are burned to death by spilling the liquid upon the clothing, or upsetting lamps or cans; and most of the explosions reported are accidents of this nature. Exemption from danger is secured only by preventing inflammable liquids from entering the dwelling — not by the use of "safety lamps" or vessels for holding the liquids. Have nothing to do with these devices. Purchase and use only good kerosene oil, of legal standard, and you are safe.

THE ATLANTIC CABLE.

A friend intimately connected with the working of the Atlantic Telegraph Cable, informs us that the insulation is growing more perfect from month to month, and that the first, laid four years since, leaks less than the last one. The loss, at the present time, does not reach *half of one per cent* upon both cables. This is surprising, and very encouraging to the owners of the line. The extreme cold of the deep sea basin, in which the wires repose, is favorable to the retention of the electrical impulses in the channel provided for them. The time consumed in charging and discharging the conductors is a bar to rapid communication; but this is to be overcome by new methods of insulation. A device has recently been brought forward which promises to fully remove this obstacle, and thus enable submarine cables to perform double the work in the same length of time. The success of deep sea cables is now fully assured, and we may look for a large increase in the number during the next quarter of a century.

DESTRUCTION OF TREES BY STREET-GAS.

Many a city and town has had to deplore the loss of fine shade-trees, by carburetted hydrogen gas coming in contact with their roots, and poisoning them by being absorbed. There is a strange instinct in the roots of plants or trees. As if they had eyes to see, they bend and stretch in the direction from which they can derive nutriment; and, wherever they can have free and easy access to the soil, and find food, there the number and thickness of the filaments are augmented. If we plant a tree in hard, unyielding soil, it will struggle most wonderfully to sustain itself, by pushing its roots through the packed earth. If, under these circumstances, a trench is dug ten or even twenty feet from the tree, filling back the loosened earth again into it, the roots appear to be cognizant of the fact, and commence a struggle with the impacted soil, to reach the trench; and this fact explains how it is that the roots of trees are destroyed by gas. The trees upon the sides of streets are placed in hard soil; and when the trench is dug for the gas-pipes, and the earth returned, the roots instinctively push for the trench as a point of relief, or where food can be more easily secured. We have seen gas-pipes, after having lain for several years, perfectly covered with a network of roots proceeding from the neighboring trees. Now, if there is the slightest leak in the line of pipe, the gas moves in the direction of least resistance, and that is along the trench in which is placed the pipe; hence, the tender spongioles are presented with strange and poisonous food, the gas is absorbed, and the tree dies.

We can hardly suggest a remedy for this great evil. It may be well to compel gas companies to cover their pipes, in the vicinity of trees, with a thick coating of cement, or plank the walls of the trench, so as to prevent the tree-roots from passing through. The loss of fine shade-trees in cities and towns is almost irreparable; and every practicable method should be adopted to prevent it.

THE LIQUORS WE DRINK.

The recent disclosures, in New York, regarding the character of the alcoholic liquors sold in the city, although somewhat sensational, are, nevertheless, worthy of serious attention. Every practical chemist, who has taken the trouble to investigate, has a clear understanding of the abominable character of the liquors retailed at shops and bars. We have known, for several years, that the liquors retailed at fashionable hotels and what are known as "first-class" bars, were greatly attenuated and mixed. It may not be, in all cases, that the proprietors or their agents adulterate; for the purchases they make of "first-class" dealers are "demoralized" to a fearful extent by both producers and importers. The *fusil oil*, found almost universally in brandies vended at fashionable hotels and drinking-saloons, results from the admixture of cheap whiskey with the brandy. The flavor, or *bouquet*, of true old brandy is so pervasive, or persistent, we have found, by experiment, that *seventy per cent* of low grade whiskey may be mixed with it, and no one can detect the fraud by taste or smell. Brandy, before being placed in decanters for retailing by dealers, is often subjected to at least two processes, which are not regarded as exactly fraudulent or reprehensible. The first is to add whiskey and sugar, and then water, to bring the proof down to the lowest safe point. The object of liquor drinking by the imbiber being to please the sense of taste and secure alcoholic exhilaration, the vender feels justified in securing these ends at the lowest possible cost to himself. If no positive or active poisons

are used to reach these results, no harm is done, and his pockets are filled more rapidly. Cheap whiskey intoxicates as well as dear brandy; and if sugar and a small amount of brandy-flavor cover the taste and satisfy the palate, why not furnish the mixture? This is the reasoning, or excuse, if conscience is ever aroused. A mixture of two parts of cheap, factitious, home-made gin with one of the true "Hollands," forms a liquor worthy a place at the most aristocratic bar, and plenty of genteel customers are found to pay twenty-five cents a glass for it. If it has an "odd" taste, it must be good, as it is dispensed by a most reputable dealer. Whiskey at first-class bars is generally a very fair article; the proof, however, is usually below standard, not rising higher than 30 or 35 per cent alcohol, when it should be 45 or 50 per cent. The wines — what of them? As a class, they are worse than other liquors, no matter how costly they may be, or who is reputed to have made them. We recently examined a bottle of champagne, taken from the hands of the importer, with a name upon the label which has the highest repute in this city, and it was found to be factitious and poisonous. The whole business of manufacturing and vending wines and liquors, both in Europe and this country, is sadly demoralized; and the more generally this fact is understood, the better it will be for community. Our young men and our old men who are in the habit of patronizing first-class bars, should understand that they fare but little better, as regards the character of the liquors they drink, than if they drank at the bars of low groggeries or dance cellars. In another column we present formulæ by which liquors are manufactured.

A FEW THINGS THAT ARE TO BE.

Before the imprint of the *Journal* bears the date of 1900, science and art will have so advanced as to have effected complete revolutions in many of the industrial processes and methods of securing health, comfort, and convenience to the human race.

Vast gas-manufactories will be found in all the great cities and towns, in which the invisible agent will be manufactured solely for the purpose of cooking the food and warming the dwellings of the inhabitants. These works will be independent of those established for making illuminating gas. It will not be necessary to purify the fuel gas so fully, and it will, in most places, be made from wood. The cost will be so low, and the conveniences so great, other kinds of fuel will, in a large measure, be dispensed with. No ashes, no smoke, no dust — what a glorious realization this will be! At that time, the air, the earth, and the sea will be full of conducting wires, and electric currents will flow constantly in every direction. A new order of things will prevail in our post-offices. The click of the telegraph instrument will be heard, instead of the snap of the lock which closes up the wide mouths of the mail-bags. The small sum of ten cents (perhaps less) will place correspondents in instant communication with each other, no matter how widely they may be separated. Although the industrial arts will have enormously increased, less steam-power will be employed. Electrical, or some other of the hidden forces of nature will be harnessed to the primary moving wheels of the great manufacturing establishments, and smoke and vapor will no longer mark their location to the distant traveller.

The sick will not be required to swallow disgusting doses of medicine. Remedies will be administered through other avenues than the stomach. Chemistry will have eliminated the vital, active principles from all curative agents; and, through the cellular subcutaneous coverings, and by other at present closed doors of access, the influence of therapeutic agents will be brought to bear directly upon diseased parts. Light will be let in upon nearly all the organs of the body, so that the physician can *observe* the extent and nature of disease, and no longer be compelled to diagnose in the dark.

The publishers of this and other journals will perhaps be able to issue simultaneous editions in all the great central cities of the country. A knowledge of practical science will be more generally diffused among the people, elevating and improving the masses, and consequently rendering them happier, healthier, and better fitted for the duties and responsibilities of life.

Kerosene. — It is gratifying to notice the waking up of cities and towns to the importance of enforcing the laws relating to the sale of dangerous burning-fluids. In New York, most efficient measures have been taken by the Board of Health, to prevent the sale of naphtha or liquids inflammable at a point below 110° F. Providence, R.I., two years since, promptly acted in the matter, and not a gallon of adulterated kerosene can be purchased there, and not the slightest accident has ever occurred in that city. Let the good work go on. We can stop all so-called kerosene accidents by the simple performance of duty. In Massachusetts, upon the petition of six citizens of any town, the selectmen are required to appoint a competent inspector of all burning-oils offered for sale.

BOOK NOTICES.

The Cambridge Course of Physics.

The Cambridge Course of Physics consists of a series of text-books for schools, embracing a treatise on Chemistry, Natural Philosophy, Astronomy, etc., by two well-known and highly accomplished teachers in the High School at Cambridge, Mass., — Messrs. W. J. Rolfe and J. A. Gillet. We have carefully examined these books, and find them to be compiled with great accuracy and care; and the arrangement of topics and the general style is admirable. The pleasing perspicuity and commendable exactness with which the elementary principles and facts of the physical sciences are presented in these treatises, are in marked contrast with a number of text-books which have somehow found their way into many of our schools. The series has appeared none too soon; and the attention of educators and those who have the supervision of our educational institutions should be at once directed to a class of text-books in which are found but few errors and blunders, and which present the results of the most recent research and experimental inquiries in a manner easily to be understood by youthful minds. The clearness of the type, and the elegance of the numerous cuts scattered through the books, can hardly be surpassed. Messrs. Woolworth, Ainsworth & Co., Boston, are the publishers.

A Conspectus of the Medical Sciences: Comprising Manuals of Anatomy, Physiology, Chemistry, Materia Medica, Surgery, etc., for the use of Students. By Henry Hartshorn, A.M., M.D. Philadelphia: Henry C. Lea. 1869.

This volume may be regarded as presenting a combination or association of somewhat brief manuals or hand-books of the medical and collateral sciences. It is intended to aid students during the months of their attendance upon the courses of medical lectures, and furnish a book of ready reference to those engaged in the active duties of the profession. It gives, in a brief form and clear manner, the indispensable elements of a course of medical study, as taught in colleges, and very properly, we think, excludes individual opinions and unsettled theories. The work is a useful one, and appears to be compiled with great care, and arranged in the most judicious manner.

Materia Medica for the Use of Students. By John B. Biddle, M.D., Professor of Materia Medica in the Jefferson Medical College, Philadelphia. Third edition, enlarged, with Illustrations. Philadelphia: Lindsay & Blakiston. 1868.

Prof. Biddle has found it necessary to issue a third edition of his "Materia Medica," in which many additions and improvements are made. The new remedial agents are introduced, and their dose, therapeutic action, etc., given. Among the agents regarded as new, are Calabar bean, woorara, mate, the sulphites and hyposulphites, carbolic acid, iodide of ammonium, iodoform, etc., etc. Most of these will be regarded as *old* by the readers of the *Journal*, as we long since called attention to them. The work contains much not found in Wood and Bache's Dispensatory, or other of the special treatises upon materia medica.

The Physician's Daily Pocket Record: Comprising a Visiting-List, many useful Tables, etc. By S. W. Butler, M.D. Philadelphia. 1869.

We should have noticed Dr. Butler's most excellent and convenient *Pocket Record-Book for Physicians* at an earlier date; but it was mislaid, and thus escaped observation. We can hardly conceive of any thing more useful for medical men than this little book. Beside the blank portion for daily records, it contains a list of new remedies, antidotes for poisons, urine tests, table of proportional quantities, etc., etc. Although a portion of the year has passed, it will still be found worth more to the physician than the cost. It can be procured at the office of the *Medical and Surgical Reporter*, Philadelphia.

Medicine and Pharmacy.

TREATMENT OF PULMONARY CONSUMPTION.

The *London Lancet* has recently contained a series of articles of a very interesting and important character, upon the above subject, by Dr. Chas. J. B. Williams and Dr. T. Williams. The last of the series of papers presents the summing up or the results of the observations and experiments of the distinguished authors. There is so much that is practical and instructive in the paper, we are led to present to the readers of the *Journal* some brief extracts worthy of special attention. The author says: —

"On taking a retrospect of an experience of forty years in the treatment of pulmonary consumption, I can trace a remarkable improvement in its success, as judged by the results. During the first ten years of that period, the beneficial effects of the treatment were very limited, being chiefly confined to incipient cases, and to those who were able, at an early stage and for long continuance, to resort to more favorable climates, such as can be obtained by voyages to Australia or India. My general recollection of the histories of the developed disease at that time is that of distressing tragedies, in which no means used seemed to have any power to arrest the malady. The tardative and palliative treatment employed was little satisfactory; and life was rarely prolonged beyond the duration of two years, assigned by Laennec and Louis as the ordinary limit of the life of the consumptive.

"In the next period of ten years (from 1838 to 1843) a marked improvement took place in the results of treatment, apparently in connection with the habitual use of mild alterative tonics, as they might be termed, particularly iodide of potassium with sarsaparilla or other vegetable tonic. These were first given in conjunction with liquor potassæ or an alkaline carbonate; but the lowering effect of the alkali led to the substitution of a mineral acid, generally the nitric; and a combination of this description (iodide of potassium, two grains; dilute nitric acid, fifteen drops; tincture of hops, and compound fluid extract of sarsaparilla, of each one drachm; with an ounce of water or an infusion of orange-peel) became

the favorite prescription, until it was superseded by something which was more efficacious. Several of the earlier of the cases recorded were treated in this way, and with improved results in respect of the general health of the patients, and diminution of the cough and expectoration."

EFFICACY OF COD-LIVER OIL.

Dr. Williams's views regarding the efficacy of cod-liver oil in pulmonary consumption, correspond with those of all careful and observing physicians in this country. So far from the oil being "out of fashion" here, there has never been a time when its usefulness was more generally recognized, or when it was more largely prescribed by physicians. It is the sheet-anchor of hope in thousands of cases:—

"It was in the latter half of this period, that chemists began to produce cod-liver oil of sufficient purity and freshness to be fit for the human stomach; and I have no hesitancy in stating my conviction that this agent has done more for the consumptive than all other means put together. And so far is this remedy from having 'had its day, and gone out of fashion,' that, in my experience, its usefulness and efficacy have gone on increasing in proportion to the greater facilities for obtaining it in a pure state, and to the improvements in the manner of administering it, in combination with various tonics, and in connection with certain rules of diet and regimen. Many of the cases narrated in the preceding papers are striking proofs of the efficacy of this remedy, not only in the general results of cure or prolongation of life, but also in detached passages of the abridged histories, in which improvement or deterioration in the symptoms corresponded respectively with the regular use of the oil, or its discontinuance."

BEST METHOD OF TREATMENT.

"In conclusion, I will endeavor to give a brief general view of the treatment which I have commonly adopted. As we have been led to conclude that consumption is essentially a disease of degeneration and decay, so it may be inferred that the treatment, for the most part, should be of a sustaining and invigorating character. Not only the most nutritious food, aided by a judicious use of stimulants and of medical tonics, but pure air, with such varied and moderate exercise in it as the strength will bear, and the enlivening influence of bright sunshine and agreeable scenery and cheerful society, are among the means best suited to restore the defective functions and structures of frames prone to decay.

"In former years, in this country (as still in many places abroad), the antiphlogistic and starving plan was carried on too long and too far; but it appears to me that there is now a tendency too much to the opposite extreme, so that consumption is treated too exclusively with tonics, stimulants, and full diet. I quite admit that this is the better extreme of the two; and it may fairly be stated that the sooner and the more constantly patients can be treated on this plan, the better. But, in case of active inflammation, continued heat of skin, hard, racking cough (dry, or with viscid and tinged expectoration), much pain or soreness of the chest or side, it answers well to withhold or withdraw the stronger stimulants and tonics, and for a time—it may be a few days only—to substitute cooling and soothing remedies, with moist epithems or counter-irritants on the chest, and, more rarely, local depletion. But this discipline, which is exceptional, should as soon as possible be replaced by what may be called the regular treatment by cod-liver oil and tonics, and a more generous diet. The transition need not be abrupt. So far as regards cod-liver oil, and the mild acid tonics, with which I generally combine it, the change may be made long before the inflammatory complication has subsided. A dose of these may be given after the morning, and perhaps after the midday meal, whilst still the saline is taken in the evening and night, and whilst blisters or other counter-irritants are in full operation.

"So soon as the nocturnal heat of skin subsides, and the cough becomes less urgent, and the urine more free, the salines may be replaced by a mere cough linctus, if that be needed; the counter-irritation moderated, and the tonic, given with the oil, gradually strengthened by the addition of salicine, quinine, or iron. These two last tonics are of great use where they are well borne, as their influence in strengthening the muscular system and improving the condition of the blood is greater than that of any other drug; but their use requires much discretion and watchfulness, for they often increase the lingering or intercurrent inflammations, with their attendant pain, constriction, cough, and viscid expectoration; and not unfrequently they derange the functions of the stomach and bowels. It therefore often happens, where the patient cannot be seen frequently, that it is safer to be content with a milder tonic—such as calumba, cascarilla, or chiretta—which may be continued for weeks and months together, in conjunction with the oil, than to give those that are more powerful, but which, by occasional disturbances, may prevent the continuance of the remedy.

"But the great remedy, more essential and more effectual than any other, is the cod-liver oil; and we may well bestow a little consideration on the mode of using it to the best advantage.

"It is now pretty generally admitted by the profession, that the pure, pale oil, simply extracted from the fresh, healthy livers of the fish, is that most suitable for the majority of patients, as being less unpalatable and at least as efficacious as the impure kinds. Since I first recommended this pure oil (*London Journal of Medicine*, January, 1849), it has been so extensively prepared and used, that it is now one of the most important articles in the materia medica; and the universality of its introduction is a strong proof of its claim to public favor.

"On the mode of operation of the oil, and on the best methods of administering it, I have little to add to what I published twelve years ago ('*Principles of Medicine*,' 3d ed., p. 487). To that I must refer for details that would be too long for quotation here; but I may give the following brief summary of my opinions and experience on the subject.

"Cod-liver oil, when taken into the system in sufficient quantities, and for a sufficient length of time, acts as a nutriment, not only adding to the fat of the body, but also promoting the healthy growth of other tissues, and, in some way, as an alterative, counteracting the morbid tendency to the proliferation of the decaying cells of pus, tubercle, and kindred cacoplastic and aplastic matters.

"That its efficacy depends much on its being absorbed freely into the blood, and through the circulation pervading all parts of the body, and thus reaching to the very seat of morbid deposits and formations.

"That the more fluid part of cod-liver oil surpasses all other oils and fats in the facility with which it forms emulsions, which are tolerated by the stomach and readily absorbed into the blood, without causing the nausea and bilious derangements that commonly result from an excess of fat food. This peculiarity may depend on the biliary and other matters contained in the oil, which in other instances of disease is found to act beneficially on the liver and other secreting organs.

"That the best time for the administration of the oil is immediately after, or, to those who prefer it, at or before a solid meal, with the constituents of which the oil becomes so intimately blended that it forms a part of the chymous mass, and is less likely to rise by eructation than when the oil is taken into an empty stomach. From this chymous mass, the oil, being absorbed through the lacteals with the chyle, is less apt to disorder the liver than if absorbed through the veins of an empty stomach.

"That, as the use of the oil should be continued for a long time,—perhaps for months, or even years,—it is of great importance to conciliate the palate and stomach by giving it in a vehicle that will disguise its flavor and strengthen the stomach to bear it. For this purpose, an aromatic bitter, such as the compound infusion of orange-peel, acidulated with mineral acid, both to help to cover the taste of the oil and also to suit the stomach, which should be duly supplied with acid during digestion, generally answers well. Syrup may be added, according to the taste of the patient; or, still better, some bitter tincture, such as calumba, cascarilla, or quinine, in every case where it is desirable to improve appetite and tone. In cases of peculiar weakness of stomach, with tendency to retching or nausea, strychnia, in a dose of from 1-32d to 1-24th of a grain, proves a most valuable adjunct to the vehicle. By its means, I frequently overcome the fastidiousness of stomach arising from debility, hysteria, or indulgence in alcoholic liquors. Salicine is another efficacious alternative of the kind. Either of these, although a powerful tonic, has none of the heating properties of quinine or iron. When the strong bitter taste is objected to, a pill, containing extract of hop or chamomile, or salicine, or quinine, may be taken after or before the oil and its vehicle.

"The bulk of the whole dose of oil and its vehicle should be small, so that it may be swallowed at a single draught; therefore the vehicle should not exceed a tablespoonful, with, at first, a teaspoonful of oil, to be gradually increased to a tablespoonful. The dose of oil should rarely exceed a tablespoonful twice or thrice daily; when a larger amount is taken at a time, generally either it deranges the stomach or liver, or some of it passes unabsorbed by the bowels.

"The acid may be varied, according to circumstances. The nitric generally suits best in inflammatory cases and those attended with much lithic deposit in the urine; but its tendency to injure the teeth is an objection to its long continuance. The sulphuric is more eligible where there is liability to hæmoptysis, profuse sweats, or diarrhœa. But, in most cases, and for long continuance, I have found reason to prefer the diluted phosphoric acid, which may be termed the most physiological of the acids, tending to derange the chemistry of the body less than the others.

"With some individuals the oil agrees so well, and so much improves their digestive powers, that they require few or no restrictions in diet, but this is not the case with the majority. The richness of the oil does prove more or less a trial, sooner or later, to most persons; and, to diminish this trial as much as possible, it obviously becomes proper to omit or reduce all other rich and greasy articles of food. All pastry, fat meats, rich stuffings, and the like, should be avoided, and great moderation be observed in the use of butter, cream, and very sweet things. Even new milk in any quantity is not generally borne well during a course of oil; and many find malt liquor too heavy, increasing the tendency to bilious attacks. A plain, nutritious diet of bread, fresh meat, poultry, game, with a fair proportion of vegetables, and a little fruit, and only a moderate quantity of liquid at the earlier meals, commonly agrees best, and facilitates the continued exhibition of the oil in doses sufficient to produce its salutary influence in the system.

"Such are the directions which have proved most effectual in the administration of a remedy which may truly be said to have so much altered the prospects of the consumptive as to give hope of cure in not a few, and of much prolonged life in by far the greater number. But, to induce patients to follow these directions, and to overcome their aversion to a remedy that the prejudices of some represent as disgusting, and the experience of many may find trying to continue for so long, the practitioner will often find it necessary to use all his powers of argument and persuasion."

HYPOPHOSPHITES OF LIME AND SODA WITH COD-LIVER OIL.

We are pleased to find these distinguished physicians have had their attention directed to the *hypophosphite salts* in connection with the oil. We have, as our readers are aware, been led to combine the salts with the oil, in a form convenient for use, and also have called the attention of medical men to the combination. We did not know, until Dr. Williams's article appeared, that any one on the other side of the water had suggested the remedy. We think it will be found of much service:—

"The hypophosphites of soda and lime, so strongly recommended by Dr. Churchill, of Paris, have in my hands proved decidedly beneficial in certain cases. They have been tried by Drs. Quain and Cotton, at the Brompton Hospital, with only negative results; but, having met with several patients who distinctly ascribed their improvement to Dr. Churchill's treatment, I have thought it right to try them myself, both as a substitute for the oil, and in addition to it. . . . . . It has happened to me, in several cases, that a patient has long been taking the oil, and, after having derived great benefit from it, halts in his improvement, or even loses ground;

and then the addition of the hypophosphite has been followed by a marked change for the better. Flesh and strength have been gained, and the chest symptoms have been more or less improved. . . . . In my mixture of the hypophosphite with phosphoric acid, I presume the hypophosphorus acid is set free, and is the active agent in the compound. How it acts is quite uncertain. I cannot say that I quite agree with Dr. Churchill's views on the subject, even if I understand them. These hypophosphites seem to increase the failing powers of respiration and circulation. Can this be by increasing the affinity of the blood for oxygen, so that it can attract it and maintain the blood changes, even under the increased difficulties and obstruction produced by disease?"

REMEDIES BY INHALATION.

"In connection with this subject, I must notice remedies administered by inhalation, which are really useful in certain cases — chiefly those in which the larynx and trachea are much affected, and in those attended with convulsive cough or offensive expectoration. I have generally found the use of inhaling instruments fatiguing and unnecessary. A quart-jug of hot water, with a napkin from over the nose down to and around the jug, to confine the steam, is all that is needed. To the hot water is added the drug to be inhaled; and creosote or carbolic acid, iodine, chloroform, oil of turpentine, and juice or extract of hemlock, are the articles which I have found most beneficial. A few drops of one or of several of these combined, being put into the hot water, the inhalation is practised through both mouth and nostrils without restraint or difficulty, and may be continued for five or ten minutes every night, and, if need be, repeated once or twice in the day. Although the chief operation of this medicated vapor is on the guttural and bronchial surface, yet a portion penetrates into the lungs, and is absorbed into the system; for iodine and oil of turpentine can be detected in the urine within a few minutes of the inhalation being made. Still, although proving very serviceable in certain cases, I cannot rank inhalation higher than as a subordinate remedy in the treatment of consumption. I may add, that the practice of painting the chest with the tincture of iodine every night, as a gentle counter-irritant, is not without a certain influence in the way of inhalation; for a portion of the iodine evaporates, and slightly impregnates the air around the patient, and this atmosphere of iodine may not be without its influence for good."

CHANGE OF AIR AND CLIMATE.

"Of far more importance in the treatment of consumption is change of air and climate. It is of the greatest consequence to the phthisical invalid that he should breathe as pure an air as possible, and that the influence of this pure air on the blood and on the body should be increased by such gentle and varied exercise in it as his strength and condition of his organs will permit. This is the great object of our sending him to a warm climate in the winter, and to a high and dry locality in the summer, that he may be as much as possible in the *open air*, with its exhilarating, vivifying accessories of light, purity, and freshness, without the chilling operation of cold and wet in the winter, and the enervating and exhausting influence of oppressive heat in summer. I cannot in this place pursue this important subject into the details of its application to the different forms and stages of disease, and the varieties of air and climate most suitable for them; but I may refer you to my son's little work on climate* for concise information on these points. I would only add further, in conclusion, that several of the most successful cases which have been recorded in these papers are illustrations of the great benefits to be derived from well-directed voyages and change of climate, in addition to the treatment which has been surmised in the present pages.

"In conclusion, I trust that the preceding papers have proved what I stated at the commencement — that, powerless as medicine is in the overwhelming of rapid types of pulmonary consumption, it has yet considerable influence over the milder forms; and *that, under careful treatment, life may be prolonged for many years in comfort and usefulness, and, in not very few cases, the disease is so permanently arrested that it may be called* CURED.

* "The Climate of the South of France, and its Varieties most suitable for Invalids." By Charles Theodore Williams, M.B.: Oxon, 1867.

Familiar Science.

THE ANILINE COLORS.

Every one has heard of the aniline colors, has seen some of the beautiful shades of color produced on textile fabrics by their agency, and knows their source; *i. e.*, that they are made from coal-tar. Few, however, know how they really are made, and very few know what obstacles have been met and overcome, and within how short a space of time their manufacture has become one of great importance, and their use has extended to almost innumerable applications. The manufacture of the aniline colors is one of the most interesting of the applications of science to the arts, especially since, from its recent growth, it has had no old traditions to check its progress, and also because we are thus enabled to trace its development, from the discovery of the first aniline dye, in 1856, to its present vast proportions. Aniline is found in coal-tar, but only in small quantity, not worth extracting. It is, however, prepared artificially, in large quantities, from the benzols obtained from coal-tar. Benzol is a general name given to a number of hydrocarbons produced by the distillation of coal-tar. The manufacturer divides them into light and heavy benzols, according to the temperature at which they distil. Examined chemically, we find them to consist of a number of hydrocarbons in varying proportions, called benzol, toluol, cumol, cymol, etc. The next step is to convert these benzols into nitro-benzols. This is done by treating them with strong nitric acid, under appropriate conditions. The nitro-benzols thus obtained, exposed to reducing agencies, are transformed into anilines. This transformation is brought about, ordinarily, by mixing them with iron and acetic acid. The action of the acid upon the iron liberates hydrogen, which acts upon the nitro-benzols, reducing them to anilines.

We are now at the starting point of the color manufacture itself, having a method by which we can obtain, in any quantity, the substance from which every one of the dyes is derived. But the observant reader will have noticed that since the benzols first obtained from the coal-tar were mixtures, so must both the nitro-benzols and the anilines be mixtures also. Such is indeed the case. The aniline oil, as it is called, that is used in color making, and the method of whose formation has just been sketched, is a mixture of basic substances resembling ammonia; in fact, they are what are called compound ammonias, or amides, being formed upon the type of ammonia. Aniline oil consists mainly of aniline and toluidine, with less quantities of other similar bases, its boiling point varying according to its constitution; anilines containing larger proportions of aniline or other bases, with low boiling points, being called light anilines, and *vice versa*.

In the early stages of the aniline manufacture, the aniline red was the most important of these dyes, and the one which first attracted public attention. This red was first called fuchsine, a name derived from the fuchsia, whose color it strongly resembles. This appellation is still used by the French and Germans; but in England and this country this beautiful red coloring matter is better known as magenta. It was first brought into the market during the Italian war, just after the battle of Magenta, whence its name. But in a very short time after its discovery the progress of the aniline color manufacture was so great that it very soon lost its importance as a dye-stuff only, being no longer a product, but itself a raw material, the first stage in the preparation of other colors. Magenta, or rosaniline, to use its chemical name, is now the starting point for making nearly all the aniline colors in actual use; and since a green has recently been made from it, the series has become perfect, and we have aniline red, orange, yellow, green, blue, indigo, and violet.

It would be foreign to our purpose to enter into any details of the process for preparing magenta. It is sufficient to say that it is an oxidizing operation. Of the many methods proposed, that one involving the use of arsenic acid as the oxidizing agent is the only one that is now in general use. As at first employed, the workmen were in constant danger from exposure to the fumes of arsenic; but it has since been so improved that it can now be carried on with perfect success and impunity. There is one point, however, in connection with the manufacture of magenta that should be mentioned. Although, from the classical researches of Hofmann, we are acquainted with the composition of rosaniline and its salts, yet the reaction by which it is formed has not been clearly made out. Nevertheless, one thing is known: that neither aniline nor toluidine alone will yield a particle of red color under treatment with arsenic acid or other oxidizing agents; but when they are mixed in the proper proportions, the operation becomes a very easy one. Magenta, or rosaniline, is usually prepared for sale either as a hydrochlorate or acetate, and can be obtained very pure in commerce.

Blue and violet colors of great beauty are made from rosaniline. There are numbers of them, of different shades and characters; but the methods of making them are of more interest to the chemist or manufacturer than to the general reader. Two aniline greens are in use. The story of the discovery of one of them is a very singular one. As told by Dr. Hofmann, who says he heard it from the author himself, it is as follows: A certain dyer, M. Cherpin, was experimenting on an evanescent blue color, which, in spite of all his exertions, he could not fix upon his fabrics. Almost discouraged by the failure of all his expensive experiments, he one day confided his troubles to a friend, a photographer. "Fix the blue?" said his friend. "Is that the only difficuly? Why, it's the easiest thing in the world! Have you tried hyposulphite of soda?"—"Hyposulphite of soda? *Mon Dieu*—no! Do you think it will fix my color?"—"Of course it will. Don't you know that hyposulphite of soda

is the fixing agent *par excellence*, and that, when we want to fix anything in photography, that is the substance we always employ?" Happy is he who possesses faith! Cherpin tried hyposulphite of soda; and his joy and admiration of the chemical knowledge of his friend may be imagined when he saw his blue transformed into a splendid green, this time perfectly stable. It is scarcely necessary for us to add that the mode of action of hyposulphite of soda in this case is entirely different from its photographic action, and that it would be quite impossible to predict the one by knowing the other.

This anecdote contains a moral. It shows, in our opinion, not the result of chance—for that is common to all the world; for where is the discovery to which chance has not more or less contributed?—but it shows the power of the will, the power of perseverance. Chance only favors two kinds of persons—those sufficiently instructed or endowed with talents eminent enough to observe it, to seize it, and to profit by it; and those who, by patience, perseverance, and the power of their will, force it, in time, to become useful to them.

Aniline yellows and browns are made, some of them of great beauty. Aniline black is, at the present time, attracting a good deal of attention from dyers and manufacturers, and is, in many respects, one of the most interesting of the aniline dyes. There is no *real* aniline black. A true black is an absence of all color; and all dyeing blacks are very dark blues, greens, or browns. Aniline black is a green so dark as to appear black. Dyers are not yet able to use this black very well on woollens; but in printing calico it is of considerable value, as it mixes well with other dye-stuffs, and forms a better basis for composite colors than logwood or iron. It possesses extraordinary indelibility. Once fixed upon the fabric, nothing will completely remove it. Acids change its color to a green; but its original tint is restored by an alkali. Some authorities state that bleaching salts will, after long exposure, discharge it; but the best supported statement is that the full black is again restored by exposure to the atmosphere.

Having thus hurriedly run over the aniline dye manufacture, two considerations at once present themselves: *First*, How much has been already done in connection with it, and to what development has it already attained? *Second*, What is there remaining undone, and what are its future prospects? The beauty of the aniline colors first introduced made them immediately very popular, and factories for their production were at once started. Very impure and high priced as they then were, the demand for them was very great, and the profit of their manufacture enormous. For instance, at that time these colors were sold in this country, impure as they were, for one hundred to one hundred and fifty dollars per pound (we do not pretend to precision); now the same dye-stuffs, well crystallized and of excellent character, can be obtained for fifteen or twenty dollars per pound. It is difficult to gather statistics of a business of such recent origin. It is enough to say that, in place of the few dyes, impure and of uncertain tinctorial power, furnished to the trade but ten years ago, they can now choose from a long and constantly increasing list of much better colors, at greatly reduced prices. In fine, within thirteen years this manufacture has commenced and has grown until it has attained a most surprising development. As yet the color manufacture itself has not been carried on in this country to any extent, but the dyes are largely used here. In Europe, however, aniline dyes are manufactured not only to supply home and American consumption, but they are sent to the East, even as far as China and Japan; and since their use requires chemicals (sulphuric acid, etc.), as well as dyeing skill unknown to the Eastern dyers, it has become necessary to send chemical products and workmen also.

Sanguine persons expect that the aniline colors will ere long entirely supplant all other dyes; but whether this ever happens or not, it is beyond question that their use will yet be very largely extended. As we continue to gain a more accurate knowledge of their constitution, we shall be better able to prepare them cheaply, and to derive from them new shades. We have, from the beautiful investigations of Hofmann, a good knowledge of rosaniline and its salts; but concerning many of the others we have only an empirical knowledge. For instance, the composition of neither the aniline green or black is understood; but when we can say just how and when they are formed, it is evident that a great advantage has been gained in the study of the best methods of preparing and using them. It is only by chemical science that the desired information can be obtained; and the manufacture has grown and can grow only as fast as the substances produced by it are studied scientifically. It is very common for so-called practical men to ridicule pure science as useless; but nothing can be more mistaken. Science and practice are really very closely connected. To be properly successful a manufacturing process must be carried on, not empirically, but in strict accordance with scientific principles. Again, reactions obtained in the laboratory are often entirely changed when tested in a practical way: *i.e.*, upon a large scale. The practical man, in order to be *really* practical, should be, at the same time, a scientific man.

So far we have spoken of the aniline colors only as dyes for textile fabrics; but this, though the principal, is still but one of the uses to which they are applied. For almost all kinds of miscellaneous coloring, they are fast replacing all other substances. Paper makers use them very largely for coloring their pulp. Colored writing and printing inks obtain their tints from the same source. Lakes for staining or coloring paper, for water-colors, and for photographic and design coloring, are made from aniline dyes. Perfumers use them for coloring soaps, pomades, unguents, essences, etc.; confectioners for tinting confectionery and syrups. It would be useless to attempt to enumerate all the applications to which they are put; and we will merely add, as examples, the decoration of glass and porcelain, coloring wood, straw, candles, ivory, mother of pearl, blueing linen, etc., etc. Not so important, though interesting, is the useful purpose which they serve in preparing anatomical specimens. Tissues soaked in their solutions absorb the color unequally, and are thus prepared for microscopic examination.

THE GREAT SALT LAKE.

BY GEO. S. CHASE.

In a trip across the continent, a few years since, the writer visited Utah and the Great Salt Lake. Some jottings from his note-book regarding the lake may possibly interest the readers of the *Journal*, although much has been written concerning it quite recently.

The Great Salt Lake is about seventy-five miles in its greatest length from north-west to south-east, and thirty-eight miles in width, extending between the parallels of latitude 41° 42′ and 40° 39′, and longitude 112° 8′ and 113° 16′. Some twelve miles due south of its south-east extremity, is situated Salt Lake City, at the base of the mountains, where a small stream affords a never-failing supply of water for household uses and for irrigating the gardens of the city, and several hundred acres of wheat-fields in the outskirts.

The road from the city to the bridge, across the Jordan, leads past the large brick-fields that supply the city with building material. The bricks are not burned, but are merely the valley mud moistened and worked over until sufficiently tempered, then moulded and dried in the sun. They are called *adobe*, and, when properly cared for, will stand for years, resisting both moisture and frost nearly as well as kiln-burned bricks. The wheat-fields extend all the way to the Jordan, a distance of five miles, and for several miles along its eastern bank. The sacred river here is very unlike its Syrian namesake, being a sluggish stream of liquid mud, some thirty feet wide by five or six deep.

On the western side of the river, beyond the reach of irrigation, is a dreary plain, with a scanty vegetation of sage-bush and cactus. This plain, which is ten miles wide, extends to the foot of the mountains which hem in the valley on the west. The road, after reaching the mountains, bends northward, and skirts their foot, making the entire distance to be travelled some twenty-two miles. The mountains, which are about three thousand feet high, are very bare except near their summits, where there are patches of timber. They are composed mainly of argillaceous schists and talcose slate, overlaid by granite and gneiss, and occasionally rolled stones and pebbles imbedded in sedimentary rock, forming a conglomerate. At one place in the latter formation we passed a cave thirty-five feet in diameter, with a low entrance, but rising in the centre to the height of ten feet. It has long been used as a camping-place by emigrants, and probably by Indians before them; and the walls and ceiling were everywhere of a shiny black, from the smoke of greasewood camp-fires.

Near the lake were three or four dilapidated farmhouses, clustered about a group of brackish springs, which boiled up at the foot of the mountain, and lost themselves, after a little distance, in a reedy swamp that extended eastward, along the border of the lake, to the opposite side of the valley. It is a singular feature of these little brooks, of which there are hundreds upon the plains, that, though they never extend far, but always sink out of sight in the thirsty sand, or end, like these, in a salt pond, before running a hundred yards, yet they are almost invariably alive with small fish, varying in length from half an inch to six or eight inches.

Leaving our horses in charge of the mistress of one of these houses, we pushed on for the lake shore. An old boat was hauled up on the sand; but it was too heavy to be moved, and we were obliged to trudge along over the rocks on foot. The range along whose foot we had been travelling ended in a bluff promontory, with a narrow beach covered with broken stones and white sand. The rocks nearest the water were covered with a thin glazing of salt, which glistened like crystal in the sunshine; and in little depressions and crevices of the rocks fine crystals of salt might be scraped up by the handful. The water-line was marked by a brown ridge, that at first appeared to be a species of seaweed cast up by the waves. The heap was fully four feet wide by a foot high in the centre, and it extended in either direction as far as the eye could reach.

Upon examination, this was found to be composed entirely of the shells or pupa cases of the larvæ of some insect, each being the size of a grain of oats. As there are no fish in the lake, the larvæ seem to have the water all to themselves, and breed in immense numbers; as both Fremont and Stansbury, in the reports of their explorations, mention meeting similar masses in other portions of the lake. The latter at one time describes the

struggles of his party in wading from their boat to the shore through a mass of living larvæ a foot deep, producing, when disturbed, a most offensive and nauseous odor. At another time, he sailed through a shoal of them covering an area hundreds of acres in extent. Fremont tells a story of a party of hunters who arrived in a half-famished state at an Indian cabin while the owners were absent. Finding a bag filled with what they supposed to be dried and pounded fish, they made a hearty meal—only to discover, when too late, that the material of their repast had been, instead of fish, these same larvæ!

The time of our visit being in September, the larvæ had long since turned to mature insects, and their empty shells were no more offensive than if they had been the chaff they so much resembled. Just released from the ever-present alkaline dust of a three-months' trip across the plains, we cared little for bird or bug; but following along the shore for a mile, to a broad bay with a smooth bottom of clear white sand, we pulled off our clothing, and plunged in for our long-talked-of bath in the famous lake. Such an extraordinary bath! The specific gravity of the water was so great that it buoyed up the body as if it were made of cork, not more than two thirds of it being at any time submerged. As for swimming, that was nearly impossible. The feet would not stay under, but, with every stroke, would rise to the surface, and waste their force upon the air.

The bay was very shallow. We waded out a long distance, the depth varying in long, regular swells from two to four and a half or five feet deep. The average depth of the lake cannot be over eight or ten feet. Stansbury rarely sounded over twelve feet; though in a solitary case he found it thirty-three.

There were no salt-crystals in the sand at the bottom of the bay; but the taste of the water was extremely bitter, and a single drop coming in contact with the eyes caused the most intense pain.

The water, though so shallow, felt quite cold,—as cold, in fact, as the water of the ocean at a New-England sea-shore watering-place. It dried off our bodies very rapidly, leaving us crusted over and the hair upon our heads filled with fine crystals of salt, which no amount of rubbing would remove, and which we were obliged to wear back to the city, where a warm bath speedily dissolved them.

In the lake, a hundred yards distant from the shore, was a rocky islet, on the sea side of which were found bits of slate covered half an inch deep with salt, forming a frost-work white as the driven snow, and almost as hard as the stone itself. In a cleft in the rock rested an old nest, probably of a fish-hawk. It was some fifteen inches in diameter, built of sticks and mud, and lined with fine grass. The stones all about it were covered with slender bones. As there are no fish in the lake, they must have been brought from some of the pools of which I have spoken, or possibly from the Upper Jordan, or Lake Utah, fifty miles to the South, which abounds in trout. A few years ago portions of the lake swarmed with birds,—ducks, brandt, blue herons, pelicans, cormorants, and gulls. Possibly, even now, on some of the lonely islands far to the north-west, or on the edge of the great barren plain, they may collect to lay their eggs and rear their young; but none were seen, except a few ducks in the marsh, and a solitary gull, who alighted on the water within gunshot, diving under and thrusting down its beak, as if fishing for something, though there was no sign of either animal or vegetable life in the water.

On the beach of this islet was picked up a little land bird that had drifted ashore. Although apparently dead for a long time, it presented no signs of decay. It was carried to the city and kept for several days, when, to all appearances, it was in as perfect a state of preservation as at the first. Indeed the water of the lake is used, to some extent, for preserving meat. Stansbury states that he preserved all that he needed for the use of his party during their explorations. Twelve hours' immersion sufficed to completely "corn" a large piece of beef, while a few days would change it into what sailors term "salt junk."

We were sorry that time would not permit us to visit the salt works, which were within sight some distance to the west of us. The business of obtaining salt by evaporating the water is carried on upon rather a small scale, as the market is limited, being confined entirely to the city and the wants of emigrants passing through. We were told that the proportion of salt varied from twenty-five per cent in the spring, to twenty-eight later in the season.* This difference in the freshness of the water is, of course, owing to the large quantity of melting snows that pour in in the spring, evaporating rapidly as the sun's rays grow more powerful. It is stated that the difference between extremes of height is sometimes twelve feet perpendicular in one season; but this is probably an exaggeration.

*Fremont evaporated, in a pail over a fire, five gallons of water, which gave fourteen pints or thirty-five per cent of a very fine-grained and very white salt. A portion of this was subjected to an analysis, giving, in 100 parts:—

Chloride of sodium	97.80
" " calcium	.61
" " magnesium	.24
Sulphate " lime	1.12
" " soda	.23
	100.00

A bottle of the water, brought home by Lieut. Stansbury, was analyzed by Dr. Gale, of Washington, D. C., with the following results:—

100 parts of water gave 22.422 solid contents as follows:—

Chloride of sodium	20.196 =	90.07 per cent.
" " calcium	0 trace.	
" " magnesium	0.252 =	1.11 " "
Sulphate of soda	1.834 =	8.15 " "
	22.282 =	99.33 per cent.

Arts.

IMPORTANT TO SMOKERS.

Dr. T. Williams, of Milwaukee, publishes in the *Chicago Medical Journal* an interesting paper regarding the influence of tannic acid upon tobacco smoke. He claims that this agent de-nicotinizes tobacco, and thus deprives it of its poisonous principle. If these statements are well founded, it will lead to combining with tobacco some of the agreeable vegetable astringents, that smokers may not have their nervous organizations broken down so speedily as by the use of clear tobacco. Dr. Williams remarks:—

"It is not generally known that tannic acid de-nicotinizes tobacco. If the bowl of a pipe is filled about one fourth full of tannin, filled up with tobacco, and smoked, the aroma of the tobacco is almost entirely destroyed, and the smoker scarcely feels the effect of the tobacco on his nervous system. In this experiment, the tannin powder does not take up all the vaporized nicotine (which is the intoxicating principle of tobacco and tobacco smoke) as it passes through it. The smoke will at first be entirely free from all taste or smell of tobacco; but in a few moments it will have formed a passage through the tannin, through which it will pass so rapidly that all of its nicotin will not be absorbed.

"The experiment is more striking if a bit of sponge is saturated with a saturated solution of tannin, and placed in the bottom of the pipe. The smoke of the first two pipefuls of tobacco will pass out as vaporless and innocent as the smoke of a child's rattan or grape-vine cigar, and as devoid of tobacco smell. But if several more pipefuls are smoked, the tannin having taken up all the nicotin it is capable of neutralizing, the smoke will begin to pass out with its natural taste and aroma. A sponge, after being used in this way, acquires a peculiar stale tobacco smoke odor. A common pipe may be used in this experiment; but with it the smoker is very liable to draw some of the tannin solution into his mouth, producing an unpleasant 'green persimmon' puckering. The Turkish pipe, which is provided with a reservoir containing water, answers the purpose admirably. The place for water may be filled with a saturated solution of tannin; or, what is better, as it prevents the unpleasant bubbling noise, a sponge saturated with the solution.

"By changing the sponge often enough, a person may smoke as immoderately as he pleases without any injurious effects; and it is particularly recommended to ambitious young gentlemen whom the weed in its natural condition 'makes sick.' I should also suppose that smoking tobacco steeped in a saturated solution of tannin, and dried, would be equally harmless, but have not tried this latter experiment. I am not sanguine, however, that mankind will avail themselves of the advantages of this discovery. It will be like the Frenchman's antidote to the intoxicating effects of alcoholic potations,—it destroys the very effect for which the poison is used.

"The North American Indians were wise, however, and availed themselves of this discovery hundreds of years ago. It is well known what inveterate smokers the Indians are; and still we never see any injurious effects of this habit upon them. This may be due, in part, to their vigorous constitutions and hardy nomadic life; but it is mainly due, I think, to the form in which they use their tobacco. Until they learn the habit from the whites, they rarely or never use the pure leaf. Their 'Killikinnick'—the agreeable aroma of which, once inhaled in a wigwam or lumberman's cabin, can never be forgotten—is composed of equal parts of tobacco and the inside bark of a species of the *cornus coricea*. Sometimes the admixture of tobacco in it is not more than a fourth. This bark is astringent, and abounds in *tannin*, and therefore in a great measure neutralizes the effects of the tobacco. The fancy brands of smoking tobacco labelled 'Killikinnick,' sold by tobacconists in papers, it is needless to say, are pure tobacco, and have no real claim to the name. The Indian name for the particular species of swamp dog-wood which they use for smoking is 'Kinnikinnick;' hence the name. As we learned the art of smoking from the American savage, it would be only showing proper respect to our tastes to take the weed as they do. They peel the inside bark of the shrub, dry it, pound it to a powder in their stone mortars, and then mix intimately with the crumbled tobacco."

Preventive of the Decay of Wood.—Experiments have been carried on in Paris for a long time, in the intent of finding out a means of preserving palings, posts, etc., from decay. As the result of a five years' experience, a paint is recommended, which at the same time possesses the advantage of being impervious to water. It is composed of fifty parts of tar, forty parts of finely-crushed chalk, five hundred parts of fine, white, hard sand, four parts linseed oil, one part of the red oxide of copper, in its native state, and, finally, one part of sulphuric acid. In order to manufacture the paint from this multiplicity of materials, the tar, chalk, sand, and oil are first heated in an iron kettle; the oxide and sulphuric acid are then added with a good deal of precaution. The mass is then very carefully mixed. It is now ready for use, and must be applied while hot. In coating the timber, a stiff brush is used. If it is found upon using that the mixture is not liquid enough, a little more linseed oil should be used. After this paint has cooled and dried, it forms a coating or varnish quite as hard as stone.

Sizing for Gold on Glass.—The following recipe has been recommended: Copal varnish is rubbed up fine with either white bole, burnt umber, or ochre—all of which must be quite dry—and then strained through cloth. The glass having been cleansed with fine chalk, is painted over with this varnish, and placed in a warm room protected from dust. Experience soon teaches when it has become dry enough for applying the leaf, which is pressed on with cotton and then allowed to dry. If necessary, it may then be polished.—*Chemist and Druggist.*

PRESERVING MEAT.

Dr. Simms, of Charleston, S. C., has a method of preserving meat, which he described at a recent meeting of the Institute of Technology, in this city:—

"Putrefaction is nature's process for returning organic to inorganic materials; and this is effected by dealyzation or change in the proportions of the gases of which the former are composed. In meats, this is brought about, as generally believed, by the action of minute animalculæ, whose germs float in the air and permeate the animal tissues. Soon after death come the monads and bacteriums, which begin the process. These must have oxygen to live, and their office is to take away the oxygen, and then die. Next come the vibrios, which are developed and can live without oxygen; and under their influence putrefaction goes on rapidly. If, therefore, by any process, we can prevent the vivification of these animalculæ, we prevent or arrest putrefaction.

"Sulphurous acid gas will do this, but this is evanescent and cannot be fixed. Though theoretically the best, it is not available in practice, as it is efficient no longer than it is in contact with the material to be preserved. Carbon is also a powerful anti-putrescent; but it cannot be used as a meat preservative, as it injures the external appearance, and attracts oxygen. In his process, he combines the sulphur and the carbon in the bisulphide of carbon, in which both the elements are fixed, thus securing the advantages of both, with the disadvantages of neither. No animalculæ can come into existence under its influence. His attention was drawn to this substance as a meat preservative by its efficacy in preserving microscopic specimens of the urinary tubuli in Bright's disease of the kidney, some of which, prepared in 1864, are now in perfect condition in the Army Medical Museum in Washington.

"This material is exceedingly cheap, much more so than salt, the estimated expense being one tenth of a mill per pound of meat preserved. To produce it it is only necessary to burn sulphur in a close retort and pass the fumes over glowing charcoal, when the escaping gas may be employed as such, or may be condensed into a fluid. He places the meat in a vat or chamber, from which the air is exhausted, by machinery if need be, which is then filled with the gas. He had preserved in this way, in September last, at Charleston, S. C., with the thermometer 92 degrees F. in the shade, a whole sheep with the skin on. This meat is now in a perfect state of preservation, as any one can convince himself by calling at 86 North Street, where the whole process can be seen in operation. As the process goes on best at a temperature of 100 to 104 degrees F., it is better adapted for warm climates, where it is most needed, than for cold ones.

As usually seen, this gas is very fetid; but it can be prepared without disagreeable odor. If necessary, the protosulphide can be used, which has rather an agreeable odor. But even with the bisulphide this gas will volatilize at 104 degrees F., in a few minutes, so that the meat is perfectly free from unpleasant odor or taste after cooking it. It everywhere permeates the muscular fibre, dissolving the fat, and carrying the oil through the whole tissue, giving a rich taste relished by many epicures."

Cement for Leather.—Of many substances lately brought very conspicuously to notice for fastening pieces of leather together, and in mending harness, joining machinery belting, and making shoes, one of the best is made by mixing ten parts of sulphide of carbon with one of oil of turpentine, and then adding enough gutta percha to make a tough, thickly-flowing liquid. One essential prerequisite to a thorough union of the parts consists in freedom of the surfaces to be joined from grease. This may be accomplished by laying a cloth upon them, and applying a hot iron for a time. The cement is then applied to both pieces, the surfaces brought in contact, and pressure applied until the joint is dry.

Japan Black.—1. Asphaltum, 3 oz.; boiled oil, 4 quarts; burnt umber, 8 oz. Mix by heat, and when cooling, thin with turpentine. 2. Amber, 12 oz.; asphaltum, 2 oz.; fuse by heat; add boiled oil, half a pint; rosin, 2 oz.; when cooling add 16 oz. oil of turpentine. Both are used to varnish metals.

TEACHERS AND THE "JOURNAL."

Editor Boston Journal of Chemistry:—

I have several times been on the point of writing to you to say that your paper ought to be better known among teachers. There is a great deal of matter in every number which is particularly interesting and valuable to the teacher, and which, in the great majority of cases, would not be accessible to him anywhere else. It is the great fault of teachers, generally, that they are somewhat behind the times in their knowledge of scientific subjects. This is not wholly their fault, but is rather to be considered their misfortune. The scientific periodicals, and the freshest books on scientific topics, are beyond the limited means of many of them; and their only authorities, in most cases, are the ordinary school text-books. These text-books are too frequently no better than the one which you have recently criticized, under the head of "Errors and Absurdities." Your little monthly would at least serve to remind these teachers that the world is not stationary. It would also furnish them a great deal of information which they could use in the way of oral instruction. I have found the *Journal* very profitable and very suggestive, in this very way; and I am confident that thousands of teachers would be eager to use it for similar purposes, if they knew of its existence. T.

Boston, Feb., 1869.

"ABOUT STOVES."

Editor Boston Journal of Chemistry:—

Is cast-iron permeable to carbonic oxide gas? Certainly not, when the metal is cold. How when it is heated?

It is a familiar fact that iron, when heated with carbon in excess, absorbes it with avidity. It is an equally familiar fact that carburetted iron,—cast-iron, for instance,—when heated in the presence of atmospheric air, gives up more or less of its carbon to the oxygen of the air.

Now the cast-iron of every stove is subjected to both these reactions. Its inner surface is exposed, while heated, to carbon in excess, and its outer surface to atmospheric air. What happens? Carbon is absorbed within, and carbonic oxide, or carbonic acid, evolved without.

When the cast-iron stove becomes incandescent,—red hot,—and the mass approaches a plastic state, is it probable that a progressive interchange of elements takes place through the whole substance of the cast-iron between the inner and outer surfaces, carbon being absorbed continuously within, and evolved, in connection with oxygen, without?

This is analogous to the well-known phenomena of electrolysis in fluids, without, however, the determining presence of a galvanic circuit.

I have not seen this view elsewhere, though it may have occurred to others. I offer it as the true explanation of the supposed permeability of cast-iron to carbonic oxide gas.

A correct theory in this case is not only of interest in itself, but may lead eventually to important practical results.

We have good reason to believe that not only the cast-iron stove, patent in more senses than one in the poor man's house, but also the cast-iron cylinder and radiator, inclosed in the furnace of nine tenths of our first-class houses, are poisoning, all winter long, the air which we breathe.

Where is the remedy? First, ventilate every room; then, either substitute steam for the hot air furnace, or use a hot water jacket, or hot water tubes, instead of incandescent iron, to heat the air. Who will invent a cheap and safe hot water furnace for our houses, which even a Celt can manage?

But who will invent any adequate substitute for the invaluable common cast-iron stove for anthracite? The nearest approach to it now is certainly the sheet-iron cylinder stove with fire-brick linings. Unfortunately this cannot replace the universal cooking-stove.

Wm. F. Channing, M.D.

Providence, R. I.

A New Element.—A new chemical element has just been discovered by spectrum analysis.

ACCIDENT FROM NAPHTHA VAPOR.

Editor Boston Journal of Chemistry:—

In conversation with a manufacturer, a short time since, I learned from him that he had lost a woollen mill by fire, caused by leakage of an automatic naphtha gas-light machine, under circumstances that are interesting. The naphtha gas machine was placed forty feet from the boiler furnace; the leakage of naphtha vapor from the machine followed the ground (precisely as water would) to the boiler furnace, which was upon a descending grade from the naphtha gas machine. When the watchman went to the boiler furnace in the morning, to kindle the fire, he placed his lantern upon the floor of the ash-pit, which was below the level of the boiler-house floor, when an explosion took place. The vapor of the naphtha being ignited by the watchman's lighted lantern, the fire ran to the naphtha gas machine in a moment. All was in flame in shorter time than this can be written. The watchman was somewhat injured. The loss from the fire was ($40,000) forty thousand dollars.

Insurance agents are observing men. They have accumulated many illustrations of the above type, and they very prudently avoid writing policies on property that is illuminated by any of the automatic self-generating gas machines.

Recently Wm. H. Perkins, Esq., F.R.S., the real discoverer of aniline dyes, in a lecture before the "Society of Arts," London, illustrated, in a very striking manner, the great density of the vapors of naphtha or benzine. He poured the heavy vapor of naphtha, or benzine, into a trough that was fourteen feet long, and slightly inclined; at the lower end was placed a lighted lamp. The vapor was seen to run down the incline until it reached the lamp, when it ignited and ran up the inclined plane to the top, precisely as a train of gunpowder would.

Mr. Perkins mentioned that in the distillation of naphthas, it was not uncommon for a leak to show itself in the apparatus, when, by its density, it would find its way to the furnace fire, and there ignite, to the great danger of life and property. F.

Lawrence, Mass.

Agriculture.

QUACK CATTLE DOCTORS.

A great deal of indignation is expressed, and very properly, against a class of ignorant men, who, styling themselves "*doctors*," tamper with the lives and health of human beings. It is certainly demanded that we reserve a part of our wrath for another class of quacks, called cattle-doctors, who are destroying hundreds and thousands of our dumb animals every year. The poor animals demand our sympathy more than human beings, whose lives are in the hands of empirics, inasmuch as no other refuge is provided for them when needing medical or surgical aid. It is indeed singular that so few educated veterinary surgeons are found in the various parts of our extended country, and no colleges are provided for the proper instruction of persons in the veterinary art. The sole resource of owners of horses and other valuable animals, when disease attacks them or surgical aid is needed, is to some ignorant pretender, who has contrived to get up a reputation as a horse or cattle doctor, and who is permitted to torture and kill in a most cruel way. We had a very valuable Durham heifer, the past season, who experienced some difficulty in dropping her first calf. A "cow-doctor" was sent for, in our absence, who commenced his course of treatment by *thrusting a large knife into the abdominal cavity*, for the purpose, as he said, of "letting out the air"! Of course the animal died almost instantly. If from motives of humanity we are not led to provide means for educating a class of veterinary surgeons, it would seem as if self-interest would awaken to the importance of the subject. According to the report of the Commission of Agriculture, Hon. Horace Capron, for the fiscal year 1867–8, the annual loss of farm

animals, from fatal maladies, reached the enormous sum of $50,000,000. The losses in swine, from "hog cholera" and other diseases, was not less than $10,000,000. These are large sums to be taken from the pockets of husbandmen and stock-raisers. Horses, mules, sheep, cows, oxen, are constantly liable to attacks of malignant disease, and it is high time a class of men were provided who, by education, are fitted to study them, and provide remedies. There should be, in every town or county, a doctor who has regularly and systematically studied the anatomy and peculiar diseases of farm animals, and who is competent to practise veterinary medicine and surgery. The vocation should be regarded as honorable and respectable, and rank with other departments of learning and art. Many of the diseases of cattle and horses are like those which afflict the human family, and require similar treatment. There are others, however, which are peculiar, and pass as murrains or distempers. These should be carefully studied, and not only curative but preventive means provided. The diseases and accidents to which our valuable animals are constantly liable should be properly treated, and the animals no longer left to suffer at the hands of vulgar empiricism or superstitious folly.

SETTING OUT FRUIT-TREES.

We heard a neighbor, last spring, call to his son, "John, have you finished digging the holes for the pear-trees?" — "Yes, sir," was the reply. A curiosity was felt to examine the "holes"; so, walking into the garden, the rows of little excavations, resembling the openings made to receive the seed in a corn patch, met the eye. The soil was hard and compact, in a condition wholly unsuited to the wants of an orchard of fruit-trees. "You will lose your trees, neighbor," we said, "if you plant them in this way; it is not only a waste of money, but a loss of time and labor." — "Why, are not the holes large enough, or deep enough? How would you dig them?" — "We never make but *one hole*," we replied, "for any number of trees, and that embraces an area equal to the whole of the ground devoted to the orchard." This digging a superficial pit in an unworked soil, in which to bury the hungry roots of young trees, is a proceeding absurd and wasteful. Fruit-trees should never be planted until the soil is in fit condition to receive them. It must be pulverized, and the subsoil turned up and exposed to air and sunshine. Good, well-rotted stable manure must be applied liberally, or ashes and bone dust, which is better. Look well to the planting of fruit-trees.

A LITTLE WHITEWASH.

Yes, a little whitewash will do a great amount of good; but a full supply, enough to cover the inside of barns, stables, cellars, etc., with two good coatings, is much better. The lime which enters into this composition is a purifying agent, and the wash serves as a disinfectant. The benefits conferred in this regard compensate for all the labor and expense involved in whitewashing; but the clean, tidy appearance which it gives to farm premises is most pleasing and salutary. In no way can a farmer make so imposing and even elegant show, for trifling expenditure, as by a free use of whitewash. Even old buildings glow and glisten under the whitewash brush, and assume a new and fresh appearance. Buildings, in the eye of the owner, as well as those of his neighbors, have a higher money value after the process is completed. The spring of the year is a good time to attend to this kind of work; and our readers, by consulting the back volumes of the *Journal*, will find some excellent recipes for preparing white and colored washes.

WHAT IS THE CONDITION OF YOUR CELLAR?

Is it damp, close, filled with disagreeable odors, proceeding from germinating or decaying vegetables? If so, it is high time you gave the matter your earnest attention; for you have in that locality the germs of disease, and yourself and family are liable to be prostrated at any moment.

You think your cellar or basement is in good sanitary condition; do you *know* that it is? Have you fairly and carefully examined the premises? Have you looked over the potatoes, turnips, squashes, and other vegetables, to ascertain their condition? We know that diphtheria, typhoid and scarlet fevers, and many other most serious illnesses have their origin in cellars, both in city and country; and we can do our readers no greater service than to urge them to see that, at all times, they are in a dry, sweet, wholesome condition. Why should farmers and farmers' families, living in the country, away from the pestilential vapors of cities, be so subject to attacks of malignant diseases? There is a reason for it, and we can point it out. They arise from the indifference manifested to the observance of hygienic rules, and the violation of sanitary laws. Cleanliness is essential to health, and it is just as necessary in the country as in the city. A family living over a foul cellar is more liable to be poisoned and afflicted with illnesses than a city family living in its polluted atmosphere, but without cellar or basement filled with fermenting roots and fruits. There is far more sickness in the country among husbandmen than there ought to be. With plenty of pure air, water, and exercise, the evil imp, disease, ought to be kept at bay; and he would be, if a better observance of certain hygienic conditions were maintained. Bad-conditioned cellars, small, close sleeping rooms, stoves, — these are all agents of evil, and are fast making the homes of farmers almost as unhealthy as those of the dwellers in cities Are not these suggestions worthy of consideration?

ASHES AND BONE FLOUR.

It is stated by many that ashes cannot be procured to make the fertilizer recommended in the February number of the *Journal*. Potashes may be employed as a substitute, by dissolving *twelve pounds* in ten gallons of hot water, and thoroughly saturating the bone flour with the solution. A barrel of dry peat or good loam, free from stones, may be mixed with the bone after adding the potash. Care must be used not to have it too moist or too dry. It should not form a sticky mass. In using, a little earth should be scattered over it before dropping the seed. The seed should not fall directly upon it. The effect of this fertilizer will not be noticed early in the season; but as it advances, the crops will become vigorous, and yield a fine return.

Editor Boston Journal of Chemistry:—

Some days ago we accidentally met with the *Boston Journal of Chemistry*, and having received more than fifty cents' worth of information from it, felt in duty bound to send in our subscription, which we did; and we *advise all interested in agriculture to do the same.* We read with pleasure your articles on bone as a fertilizer, and agree with you that it is the only safe way for a farmer to procure a good superphosphate to get the bone and make it himself. W. E. B. & Co.

PROVIDENCE, R. I., Feb. 22, 1869.

COMMERCIAL FERTILIZERS.

We are pleased to find that our exposures of frauds in fertilizers and efforts to prevent them are having an influence upon our law-makers. The following act, reported by Col. Needham, has passed the Senate of this Commonwealth, and will undoubtedly become a law before this paragraph is read. The law is perhaps as good as could be framed; and its enforcement will prevent a vast amount of loss to farmers, gardeners, etc.

AN ACT TO PREVENT THE SALE OF ADULTERATED COMMERCIAL FERTILIZERS.

Be it enacted by the Senate and House of Representatives in General Court assembled, and by the authority of the same, as follows:—

SECT. 1. Commercial Fertilizers sold or kept for sale in this Commonwealth shall have affixed to every bag, barrel, or parcel thereof a printed label, which shall specify the name of the manufacturer or seller, his place of business, and the constituent parts of said fertilizer, together with a statement of the percentage which each constituent part bears to the whole mass.

SECT. 2. Whoever sells or keeps for sale commercial fertilizers not labelled in accordance with the provisions of the first section of this act, or who shall affix thereto labels not truly specifying the constituent parts of the fertilizers, shall be punished by a fine of ten dollars for the first, and twenty dollars for the second and each subsequent offence.

COAL ASHES.

Editor Boston Journal of Chemistry:—

I consider it a favor to be able to recommend your valuable paper to my farmer friends. May I take the liberty to ask you, will it pay to draw coal ashes one mile for agricultural purposes; and in what way should they be used? Respectfully yours,

M. H. CHRYSLER.

KINDERHOOK, N. Y., Feb., 1869.

REMARKS.—Coal ashes usually contain about 5 per cent of soluble substances useful to plants. They are valuable to spread upon wet meadows; but we think they cannot be transported long distances with profit.

TICKS ON SHEEP DESTROYED BY CARBOLIC ACID.

Editor Boston Journal of Chemistry:—

For the benefit of farmers and others having charge of farm-stock, allow me to make a statement through the *Journal*. Last winter I had a flock of between thirty and forty sheep, which I found, upon examination, to be badly infested by ticks. What to do in the case was a question. For obvious reasons I could not use the tobacco dip. I had seen, in the *Journal of Chemistry*, statements that *carbolic acid* was the most effectual, and at the same time the most convenient remedy that could be found. Without delay, I ordered from you a gallon of the *saturated aqueous solution*. To apply it without waste, I made use of a small tube, passing through a cork, in the neck of a small tin can. My sheep were almost covered with ticks, and I only applied the acid along the back, sides, and neck, parting the wool so that it should penetrate to the skin. I went over the entire flock in three hours' time. A few days later they were examined, and the worst cases treated again; and subsequently a very few were attended to a third time. Two quarts of the solution was all that I used, and the result exceeded my most sanguine expectations; the whole were exterminated. At shearing time, upon most of the flock, not a single tick could be seen. Nor did they go from the sheep to the lambs; my lambs were entirely free from them.

I can say cheerfully that the aqueous solution carbolic acid, sold by you, is the cheapest, the surest, the safest, and by far the most convenient thing I ever used; and I would remark further that I have used it upon cattle with like effect. The knowledge obtained through the *Journal of Chemistry*, in regard to the usefulness of this agent for the purpose named, was worth, to me, last year, many times the cost of the paper. Allow me to suggest that in supplying this acid directions for its dilution be given. There are so few people acquainted with its nature that this seems necessary. S. AUG. NELSON.

GEORGETOWN, Mass.

PROSPECTUS.

BOSTON Journal of Chemistry.

Vol. IV.—Commencing July 1, 1869.

A PROSPECTUS OF VOL. IV. OF THE "JOURNAL" is issued at an early date,—three months before the volume commences,—with the view of informing our numerous friends regarding our plans in the future, and affording them ample time to aid us in extending its patronage, and consequent usefulness; besides, it enables us to make a very generous offer to new subscribers, the nature of which is stated below.

A very general desire has been expressed that the JOURNAL should be continued in its present form, at least through another year; and, after much deliberation, it has been decided not to make the contemplated change alluded to in the January number.

VOLUME IV. of the JOURNAL, commencing July 1st, 1869, will be of the same form and size as the present volume, each number containing not less than *nine pages* of reading matter. It will be printed with new type, on the finest book paper; and we shall strive to make it not only the *best and cheapest scientific journal in the world*, but the *handsomest*.

The terms for the JOURNAL *will be the same as heretofore,—Fifty Cents* (50) *per year; single numbers, Six Cents.*

The JOURNAL will continue to be independent, unbiased, careful, and reliable. No individual, corporation, or organization is rich or influential enough to suppress its opinions, or in any way control its influence. It will continue to expose frauds, schemes, and speculations, which profess to originate in or grow out of progress in science and art. The great and growing evil of *adulterations* in articles of food, medicine, fertilizers, and substances used in the arts will receive special attention, and the nature of the sophistications and adulterations fully exposed. We shall present a large number of useful practical formulæ, recipes, and scientific suggestions, which alone will be worth many times the price of the publication.

TO PHYSICIANS

It will continue to be of *special service*, as it will keep them informed of the nature of all new remedial agents, all new discoveries in chemical and medical science, all new principles or processes connected with toxicology and pharmacy.

TO DRUGGISTS

It will come as a reliable friend and adviser, affording information and instruction upon all matters relating to the manufacture and dispensing of medicines, and those other substances and agents produced or vended by them.

TO FARMERS

It will impart information upon the important subjects of the chemistry of plant-growths, and the nature and method of preparing fertilizing agents.

TO CHEMISTS, MANUFACTURERS, ARTISTS, TEACHERS, STUDENTS, CLERGYMEN,

ALL intelligent readers, men and women, everywhere, the *Boston Journal of Chemistry* will supply information and instruction of the highest importance and usefulness.

The JOURNAL has, at the present time, a large army of friends, and these we ask to aid us in extending its circulation. Our patrons know how instructive and useful it *has been* in the past; we assure them it will be even *better* in the future. Cannot each one send us a new subscriber, to commence with Vol. IV.?

We make this generous offer to *new subscribers*: All those who subscribe and send us *fifty cents* in advance will receive the remaining numbers of Vol. III. They will receive the whole of Vol. IV., and all the numbers of Vol. III. which are issued after the date of their subscription. *Subscribe early*, and thus obtain as a gratuity a part of Vol. III.

JAS. R. NICHOLS & CO., Publishers,
BOSTON.

Boston Journal of Chemistry.

BOSTON, APRIL 1, 1869.

☞ Any one sending us the names of three new subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For five new subscribers we will send the Petite Microscope; for twenty-five we will send, in addition to the microscope, a copy of "Stöckhardt's Chemistry for Students," the best elementary treatise yet published; for one hundred new subscribers we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stöckhardt's Chemistry.

☞ Premiums are allowed only upon *new* subscribers, not on renewals of subscription by old subscribers.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

☞ Correspondents are particularly requested to give their names in full, with their Town and State; and, in case of change of residence requiring a corresponding change in the mailing of their papers, to give not only the new address, but the old one also.

☞ Subscribers who are physicians, dentists, or apothecaries will confer a favor by informing us of their profession, as we wish to know accurately the amount of our medical subscription list.

BACK VOLUMES OF THE JOURNAL.

We are unable to supply complete files of either Volume I. or II. of the *Journal*. Of Volume I. (originally issued bi-monthly), Nos. 1, 2, and 3, (July, August, and September, 1866,) are now out of print. Of Volume II. (monthly), Nos. 1, 3, 6, and 12 (July, September, and December, 1867, and June, 1868,) are also out of print. Of the remaining numbers we have a few copies left, which we will forward to our friends at the following prices: Volume I., three numbers, twenty-five cents; Volume II., eight numbers, fifty cents. We have on hand a few complete files of Volume III., as far as published. These we will send as ordered, at the rate of six cents per single copy; six copies for twenty-five cents.

THE NEW METHOD OF PREPARING OXYGEN.

Much interest is manifested by some of our readers respecting the new method of Tessié du Môtay for preparing oxygen. We have heretofore presented a brief explanation of the method; but a desire is expressed for more explicit or detailed statements, and therefore we allude to the subject again. Like a great many *new* inventions, it is not altogether new. The great chemist, Boussingault, in some experiments with baryta, achieved similar results, and in a way not unlike that of Du Môtay. Indeed we learn that the latter has recently introduced baryta into his process; thus, in a measure, imitating Bousingault's method.

The ordinary black oxide of manganese of commerce is stirred into a solution of caustic soda, and the whole evaporated to dryness. The mixture is then placed in a retort, and a current of hot air passed over it. The oxygen of the air is taken up and combines with the substances, forming manganate of soda. The manganate of soda is then subjected to the action of superheated steam, which decomposes it, robbing it of three equivalents of oxygen, and converting it into sesquioxide of manganese and soda. The steam holding the oxygen is condensed by passing it through a coil of iron pipe immersed in cold water, and the oxygen is conveyed to a proper gas holder. This is a simple statement of how the oxygen is procured. As soon as the current of steam is stopped hot air is again passed over the oxide of manganese and soda, and manganate of soda is again formed. Superheated steam expels the oxygen as before, and thus the process is continuous, the soda manganate being formed and decomposed alternately by the action of hot air and steam. In theory the original mixture should serve an indefinite number of times; but in practice we learn that it does not, as, by partially fusing, it becomes incapable of absorbing oxygen.

The inventor, as before stated, has recently introduced baryta and some other substances into the retort, which aids in the absorption of oxygen, and prevents the semi-fusion of the mass. Considerable expense must be incurred in apparatus, as two retorts are required, and arrangements for superheating steam. The oxide of manganese and the caustic soda are cheap articles, and if they can be used over and over again oxygen can certainly be furnished at a very low cost. It will be seen from this description that the invention does not help those who wish to use only a moderate amount of oxygen It is practicable only for purposes where large quantities are required. Surgeons who require the gas for producing the intense lime light used in connection with the laryngoscope and other optical instruments, can best prepare it from the oxide of manganese and chlorate of potassa after the well-known method. Teachers and experimenters must still depend upon this simple process.

A BISHOP ON SCIENCE.

We have seen in several prominent newspapers, including one of the respectable journals of this city, extracts from a report in the *Buffalo Christian Advocate* of a lecture by Bishop Coxe, of New York. The lecture was on the "Connection of Science and Revealed Religion;" and we are told that it was "full of astonishing facts." It most assuredly was, if the report is an accurate one. For instance, we are informed in it "that the crust of the earth is *just* twenty-one miles thick; that the world's conflagration has already begun, as *the internal fires are tending rapidly to its annihilation*; that earthquakes have multiplied since the Christian era, and *indicate a speedy collapse of our system*; that if the Lisbon earthquake had been a *little* more severe the shock would have *driven out* that portion of the surface; and, *most wonderful of all*, that on the first day of the present century, a little planet was discovered by Kepler in our system; and since then a large family of these little planets have appeared, which are *parts of an exploded world*, and that some of these fragments have fallen on the earth in *showers of meteors*." After stating this last wonderful fact, the lecturer appears to have made the sapient inquiry, "If Kepler's planet exploded, *why may not ours?*"

It is pleasant to know that scientific men, who have hitherto estimated the thickness of the earth's crust all the way along from ten miles up to eight hundred, are now agreed that it is *just* twenty-one miles. It is well to have these disputed questions finally settled. It is not so pleasant, however, to be informed that the internal fires of our planet, instead of cooling down by slow degrees, as many of the most eminent students of physics have assumed, are raging more and more fiercely, and that "a speedy collapse" of the globe is to be expected. It is also unwelcome news that the strain upon the earth's crust by the Lisbon earthquake has been so exactly measured, and that a little more force would have "driven out" a piece of it; for we cannot tell how fearful may be the results of the next great earthquake, which, from the increase of earthquakes, may be expected to be "a little more severe." The consequences *may* be such an explosion of our terrestrial ball as the bishop darkly hints at in an interrogatory way.

But concerning the last of these facts, and the "most wonderful of all," we must venture to express a doubt. There is pretty good reason to believe that Kepler died in the year 1630; and we must still adhere to the commonly accepted statement that it was another man who discovered the little planet Ceres on the first of January,

1801. It is true that Olbers advanced the theory that this little planet, and the others like it which were soon afterwards discovered, are parts of a shattered planet; but we supposed that this theory was now almost universally rejected by astronomers. These planets now number about a hundred, and are scattered through a belt of the heavens more than a hundred millions of miles in breadth, or more than the distance from the earth to the sun; and it is difficult to conceive of an explosion that could throw great fragments of a huge planet through distances so vast. There are other objections to the theory which are even more serious. On the other hand, if we accept the nebular hypothesis (of which we gave a sketch in the last *Journal*), the formation of this zone of minor planets is as readily explained as the origin of our own globe, and the mightier orbs that move in wider circles round their solar centre.

Of course we do not believe that the lecturer said that Kepler discovered Ceres. He probably mentioned Kepler in that connection, and the reporter, as reporters sometimes do, got things somewhat mixed in his memoranda. But the good bishop very likely did make most of the other statements ascribed to him; for it is a common vice of unscientific writers on scientific subjects to be very rash and dogmatic on doubtful or disputed points. They frequently have no hesitation in deciding questions which wise men, who have made them the study of their lives, do not venture to consider settled.

Even if the lecturer made none of the statements in the positive form in which they are reported, there can be no doubt that the *Christian Advocate*, and the papers that have copied its report of the lecture, are responsible for the promulgation of these errors and absurdities; and it is certainly to be regretted that there is so general an ignorance of the very alphabet of physical science that these absurd things can be printed, and reprinted, and widely read without challenge or contradiction.

A NEW ANÆSTHETIC,

Or, rather, an improvement upon an old one, is proposed by Dr. E. Andrews, of Chicago. A recent number of the *Chicago Medical Examiner* contains a paper by Dr. Andrews, giving the results of some experiments with the nitrous oxide in association with certain quantities of free oxygen. The object of these experiments was to ascertain if, by mixing oxygen with nitrous oxide gas, it might not have conferred upon it a *sustaining power*, so as to be applicable to the longest surgical operations. It is well understood that, while nitrous oxide acts promptly, and leaves none but the most agreeable sensations behind, its healthy anæsthetic action cannot be very long continued. For use in extracting teeth, and for minor surgical operations, it is better and more desirable than either ether or chloroform; but for the more serious surgical cases, requiring the patient to be kept insensible for a long time, it has been found to produce unpleasant and dangerous symptoms.

The theory regarding the cause of these effects is, that the oxygen is so firmly locked up in the combination that it cannot aid in the revivification of the blood, and hence is as inert as the oxygen of carbonic acid. The nitrous oxide needs to hold in mechanical combination sufficient oxygen to sustain life while it is acting to produce anæsthesia. Dr. Andrews claims that his experiments prove that *oxygen-mixed nitrous oxide* is an agent perfectly safe to use in the longest as well as the shortest surgical operations, and that it forms the pleasantest and best anæsthetic known. He recommends one volume of pure oxygen to be mixed with three of nitrous oxide, and remarks that care must be used, in administering it, that no atmospheric air becomes mingled with it. We feel that Dr. Andrews's theory and statements deserve careful consideration, and we hope they will stand the test of the most rigid scrutiny and experiment. It is impossible to place full confidence in his results, as there is manifestly an incompleteness in his labors, and they do not rest upon that substantial basis of experimental demonstration which is demanded for matters of so important a character. His theory seems plausible, and may be correct. We sincerely hope it may prove so.

EVAPORATING WATER IN CONNECTION WITH STOVES AND FURNACES.

A correspondent inquires, — "What becomes of all the water evaporated in the hot-air chamber of furnaces? Several pailfuls are evaporated in many furnaces each week, and yet the walls and windows of the heated rooms appear dry."

If the sense of sight of the occupants of our dwellings was acute enough, many strange and interesting processes might be observed which are now entirely hidden from view. What are called "convective currents" would be seen, in heated rooms, moving upwards and downwards, the warm air ascending, the cooler descending. Constant agitation, constant motion, is maintained in all apartments, even those apparently the most quiet. Air is passing in and out of rooms through every crack and crevice, and the amount thus transferred in the course of twenty-four hours is immense. If it were not so, no one could live in-doors a single day. The air passing up from furnaces, loaded with aqueous vapor, is disposed of in various ways. The abnormal moisture is in part condensed by contact with cool surfaces in the room; a part passes out of doors; and still another portion is distributed over the dwelling, and is condensed upon ceilings, floors, windows, etc. In frosty weather, a large part is condensed upon the windows, which are rendered cool from the chilling winds without.

Families suffer in health, and dwellings are injured, by this foolish practice of evaporating water in connection with stoves and furnaces. No family should allow "several pailfuls" of water to be changed into vapor every week, to hang in the atmosphere of rooms, and impinge upon furniture and walls! A pailful of water makes seventeen hundred and twenty-eight pailfuls of steam. What an atmosphere this must produce for human beings to live in! Is it natural? Is it pleasant? Is it healthful? No. We have always found the most cases of croup, influenza, rheumatism, coughs, etc., in families who entertain the erroneous and vulgar idea that much moisture is essential to health. A better system of ventilation, a more careful adjustment of temperatures, is what is wanted in our dwellings, — not an abnormal steam-impregnated atmosphere.

CARBOLIC ACID.

It is becoming more apparent every day that our expectations regarding the value of this new agent are to be more than realized. Even with our present imperfect knowledge of its therapeutic character and capabilities, it must be regarded as a great boon to suffering humanity. When it is better understood, when it shall have been fairly studied and tested by patient experiment, the number of important uses to which it will be found applicable must be very large. In medicine, it has a twofold power; it is both a prophylactic and curative agent. Nothing that modern chemistry has suggested equals or even approaches it as an antiseptic or destroyer of contagion. We cannot avoid the belief that it is to exert a vast influence in preventing and arresting diseases of almost every nature. In measles, hooping-cough, fevers, diphtheria, scarlatina, etc., it has been found not only to mitigate the severity of the attacks, and shorten the periods, but to prevent these diseases from spreading in families and communities. These desirable results are secured, not by internal use alone, but from allowing the vapor to pervade the dwellings or rooms in which patients are confined. The form of *pure carbolate of lime* is best adapted for this purpose. A few ounces placed in saucers or other receptacles, in rooms, diffuses, when the preparation is pure, an agreeable odor, which is constant and pervasive. Many physicians are ordering its employment in all sick-rooms, without regard to the nature of the disease. The close, impure air in which the sick are often confined is prejudicial to both invalid and attendants.

Carbolate of lime is exceedingly useful in purifying the air and destroying all septic germs. The common commercial carbolate of lime is not adapted to such purposes, as it is very impure, holding many extraneous substances yielding unpleasant odors. At the suggestion of several physicians, we have been led to prepare *chemically pure carbolate of lime*, suited to household employment, and to place it in small parcels convenient for use. No family should be without this important disinfecting, purifying agent. Sufficient to meet the wants of a family for several weeks can be purchased for the small sum of twenty-five cents.

There is inexcusable ignorance among druggists regarding the nature of the agent and the form in which it should be dispensed. Quite recently, one of the most reputable of the dispensing druggists of this city filled a prescription calling for a mixture of *solution of carbolic acid* and glycerine, with the liquid in nearly a pure form. The mixture was prescribed for purulent ophthalmia and most serious results followed its application.

Two years ago, from a careful study of the new substance, we were convinced that the *saturated aqueous solution* was the form in which it would best meet all, or nearly all, therapeutic uses. Accordingly we prepared a chemically pure solution of this character, and introduced it to the notice of physicians. This is perfectly safe, and adapted to all external and internal employment, and is what is required when solution of carbolic acid is prescribed.

The *Journal* has been largely instrumental in awakening an interest in carbolic acid, and diffusing a knowledge of its history and chemical character. In this we feel a great service has been rendered to physicians and our readers generally.

SEVERAL THOUSAND DOLLARS MORE SAVED. — In the January number allusion was made to the fact that a party had saved *five thousand dollars* from reading in the *Journal* some statements regarding "*schemes*." We present below an extract from a letter recently received from a well-known gentleman in New York. He says: — "I value the *Journal* highly; I would not give it up on any account. I was pleased to see that you intended to raise the price to one dollar, and regretted to notice afterwards that it was not to be changed. An article published last summer upon *gas* prevented me from investing in the Pneumatic Gas Machine Co. here, and I now see *that it saved me from a loss of several thousand dollars*. Don't fail to send me every number of the *Journal*."

SALTS OF MORPHIA.

We have the pleasure of informing our medical and druggist friends that we can now supply our own brand of *pure salts of morphia*, in any quantity that may be desired. Our arrangements are such as will enable us to furnish the *sulphate, acetate, muriate, valerianate, etc.*, in lots of *one hundred* or *one thousand ounces*, and also, *all the acid and alkaloidal principles of opium* used in medicine.

The *sulphate of morphia*—the salt most used by American practitioners—we present in the form of beautiful, white, downy crystals, of the *highest purity and excellence;* and these are placed in vials holding ⅛ ounce each, avoirdupois. We venture to state that modern chemistry is incapable of producing the active principles of opium in greater perfection than is found in the salts we offer.

No agent is more generally used or relied upon by physicians than morphia; and hence the importance of securing it in the highest state of integrity, free from all attenuation or sophistication.

Our morphia salts may be obtained of all the principal druggists throughout the United States.

J. R. N. & CO.

TRICHINA.

The occasional occurrence of deaths from the presence of these parasites in the human system creates alarm on the part of nearly all pork-eaters. Pork infected with the worm is generally darker than usual, and it presents a speckled appearance to the naked eye. When pork is eaten containing the parasite, the cyst in which it is involved is quickly dissolved by the gastric juice, and the creature is set free. Finding itself in the midst of nourishing food, it rapidly grows; so that in two or three days it is four times its original size, and begins to penetrate deep into the muscles of the victim. To do this it *bores through the walls* of the intestines, producing terrible mischief. The most excruciating pain is produced from the inflamed muscles, and the patient dies in great agony. The pig is most commonly infested by the trichina; but they have been found in the muscles of dogs, rats, foxes, frogs, moles, and most carnivorous birds. Thorough cooking of pork destroys the life of the parasite; and therefore no cold raw ham, sausages, or uncooked pork in any form should be used. The little petite microscope so often spoken of in the *Journal* shows the trichina in a very thin slice of infected pork most clearly. They must be searched for in the lean or muscular part of the animal.

☞ The new clinical microscope devised by Dr. Cutter, of this city, and described in another column, is creditable to his skill and ingenuity. The new immersion objective, by Tolles, is first figured and described in the *Journal*, and will attract attention from those engaged in microscopical research.

Claret.—No variety of wine is more dangerous to use than what is called *claret*. It is usually a vile mixture. Thousands of gallons are made by allowing water to soak through shavings, and adding thereto a certain proportion of logwood and tartaric acid, and a little alcohol. Good judges can hardly discriminate between this factitious mixture and the genuine article.

☞ We have several book notices ready, which are crowded out of this number for want of room. They will appear in our next.

Medicine and Pharmacy.

"FASHION" IN MEDICINES.

It is quite common, both in this country and in Europe, for medical writers to speak of certain remedial agents as being in or out of "fashion." To those who do not watch the progress or course of things in the medical world this sounds strangely. Every one understands the meaning of the word "fashion" as applied to dress and some other matters, but how there can be "fashion" in remedial agents is an idea not easily comprehended. We do not exactly like the word used in such connection, and yet it has great significance. Bromide of potassium, the sulphites, carbolic acid, etc., may be said to be very fashionable this year; how they may be next it is impossible to say. One thing is certain, if they are out of fashion, or have fallen into disuse, it will not be owing to any want of inherent therapeutic excellence in the articles, but due rather to caprice, negligence, or want of intelligent discrimination in their employment. The history of the introduction and subsequent fate of most of the new remedial agents brought to the notice of the profession during the last quarter of a century is indeed curious and instructive. Some, perhaps, might not find in it the evidence of that wisdom and sagacity which should characterize the profession. Undoubtedly many hasty judgments have been formed, and erroneous verdicts rendered; but these failings are common to all professions. Some agents are in fashion at one point and out of fashion at another. There are local prejudices quite amusing. For instance, in Edinburgh, and, indeed, throughout England, the use of ether as an anæsthetic is almost entirely unknown. It is regarded as a bulky, disagreeable, unsafe agent, vastly inferior to chloroform in every particular. In this city, ether is the one grand *lethean* universally employed by surgeons in hospital and private practice. Chloroform the Boston authorities regard as dangerous and hurtful to patients, causing many deaths. This the Edinburgh surgeons deny, and accuse us of exaggeration and prejudice. The truth lies between the two. Both ether and chloroform, properly understood, are good and safe anæsthetics, and each have a useful purpose to subserve in the hands of the surgeon. There is no good reason why either agent should be denounced or regarded with suspicion by surgeons, on this or the other side of the Atlantic. No less a physician than Dr. Richardson of London has recently informed us that nitrous oxide is an asphyxiating agent, a poison sure to kill when administered to men and animals. This absurd statement caused it in a measure to go out of fashion in England, when it was becoming quite popular. We know in this country that half a million people have breathed the gas, and not a dozen cases of injury have resulted. But few thereapeutic agents suggested secure a fair and extended trial at the hands of physicians. Great interest is manifested when an alleged new discovery is made, and, for a time, the demand for any new substance is very pressing. It is used for every conceivable ill; one prescribes it for pains in the joints; another, perhaps, for extirpating ovarian tumors. For a time it is employed as if it were known to be a sovereign panacea for all human ills. Those most useful agents, the bromides, are now greatly in fashion everywhere. As they will, of course, be found entirely inefficient for the relief of every form of illness, we may expect them soon to be neglected or cast aside. Their real merits as hypnotics or nervous sedatives should not be overlooked or forgotten, because they have failed in numerous cases where they were inappropriately used. The attention of physicians has been often called to new agents entirely worthless and inefficient; indeed we may say that perhaps the majority have been of this character. If it were only such that have gone out of fashion or fallen into disuse, it would be well for physician and patient; but this is hardly the case. There are quite a number of old as well as new remedial agents of great value which are now entirely neglected or seldom employed. A few years ago how largely was the *veratrum viride* prescribed! how seldom now! Has it not been conclusivly proved that as a controller of arterial excitement this agent is without a rival? Is it not a remedy of too high value to be neglected or to go out of fashion? Columbo is an old remedy, and one of the safest and best tonics which our materia medica offers. It has bolstered up more weak stomachs, and helped to establish the reputation of more physicians, than any other remedial agent; and yet it may be regarded as hardly in fashion at the present time. It is not often prescribed, or, at least, not half often enough.

Whenever a new remedy is suggested by advancing chemistry, if its claims seem to be founded upon correct theory,—if, indeed, it appears to be worthy of any notice or trial,—the trial should be a fair one. A little superficial, hesitating, doubtful dabbling in anything settles no questions, establishes no truths, dissipates no errors. If we are ever to make progress in medical science, there must be more persistent, intelligent, independent, original investigation, and less leaning upon men regarded as medical oracles, whose views and opinions are often erroneous and liable to mislead. There is no good reason why a remedy which, after long and careful trial, is found to be useful should ever go out of fashion; and certainly it is absurd to retain in use those which are worthless and inert because they are fashionable.

VACCINATION.

A very general complaint is made by physicians of failures to produce constitutional effects with vaccine virus. The freshest and most perfect specimens fail in hundreds of cases, and there seems to be no good reason for this. It is also remarkable that vaccination appears to be less protective than formerly. Small-pox, in several localities, especially on the Pacific coast, is making alarming ravages in spite of vaccination. The son of a friend, who was clerk of one of the Pacific mail steamers, recently died of confluent small-pox, at Hong Kong China. He had been repeatedly and successfully subjected to kine-pox vaccination, but all to no purpose. Physicians who send to cities for vaccine matter should remember that its vitality is destroyed when subjected to a temperature above eighty degrees Fahrenheit. It may be frozen without harm. There is often great injustice in the complaints of physicians that *inert* virus is sent them, which is the cause of failures. We have undertaken to supply virus from kine and from healthy children; and its collection and preservation has been in the hands of one of our most careful and experienced physicians, who is indefatigable in his efforts to present it in its highest efficacy. If it has proved ineffectual, it must be due to transportation (in letters) in hot mail cars, or to other causes wholly inexplainable. Physicians' offices in which virus is kept are often heated above eighty degrees Fahrenheit, and when carried in the pocket it is soon rendered worthless. Our duties are so various and exacting we can no longer supply virus to our medical friends, and consequently they will send their orders to other parties.

A NEW CLINICAL MICROSCOPE.

BY DR. EPHRAIM CUTTER, BOSTON.

Editor Boston Journal of Chemistry: —

It cannot be denied that the live physician of the present day feels the want of a portable microscope of standard excellence, that can be used at the bedside of the patient, for the purpose of determining morbid morphological elements in the secretions, as a means of diagnosis. He wants as good combinations of lenses as he can afford to buy; but it is impossible for him to carry about in his pocket even the beautiful and superior student's microscope, made so well by the Boston Optical Works, to say nothing of higher grades of instruments. This want so pressed upon the writer that he set himself to devise a microscope which should have the nicest optical excellence, and embrace all the *essentials* of a microscope, and yet be portable. The result is depicted in Fig. 1, which has been pronounced by experienced

Fig. 1.

microscopists *all* that is necessary or desirable for a microscope which is to be used by the bedside of a patient anywhere.

It differs from the clinical microscope of Beale, in having a good adjustment by means of a screw thread cut on the tube of the instrument, and also in the form of the stage and holder. Its use is very simple. If a sediment of urine is to be examined, a drop is placed on the centre of a common glass slide. It is covered with a common covering glass. A piece of bibulous cloth or paper is then applied to the edge of the cover, and the superfluous fluid is absorbed, so that when the slide is turned upside down the cover will be held in place by the capillary attraction between the cover and the slide. The slide (cover next the microscope) is then slipped under the elastic band at one side, and the object brought over the opening in the centre of the stage. The instrument is then put to the eye, like a spy-glass, and the stage turned towards the light, it may be of a window or of a lamp. When it is remembered that a beam of light only 1-30 inch in diameter is sufficient for illumination for a 1-5 inch objective, it is easy to see that the question of light need trouble no one when in any civilized habitation. The following description by Dr. Rufus King Browne, a most eminent microscopist, was given at a late meeting of the Middlesex (Mass.) East District Medical Society: —

"This is strictly a portable microscope; that is, it can be carried wherever he goes, in his practice, by the professional man, in his breast-pocket, without inconvenience or discomfort. The same name is applied to very poor instruments; this is a very *good* one. Portable microscopes are usually of very *low* power, and are applied to very limited range of use. In this there is high power, as well as lower ones; the former as little troublesome to use, exacting as little acquired expertness of the observer, as the latter.

"I think nobody as yet has realized or embodied the conception of a portable microscope at all equal to this. It embodies not only several advantages over others, but is very *complete.* It is exceeded by the best trunnion microscopes only in the *number* of the appliances of the latter, but sums up all their other excellencies. It is a simple tube, which incloses both objective and eye-piece. It resembles in appearance an ordinary single-barrelled spyglass; but the objective is not, as of that and other microscopes, liable to be brought in contact with foreign substances. The glasses of the objective are therefore safe from this source of injury to them. The objective is entirely in the interior of the tube.

"The adjustment of it to focus for the object examined requires only a turn or two, with the left hand, of the lower portion of the tube, held toward the light by the right. This portion of the tube, extended into the shape of a flange, is the stage, upon which the slide and object is placed. It is closely held thereupon in view by an elastic ring. The bottom of the tube is closed, except a small circular opening which admits the light, through the object and objective, to the eye-piece and eye of the observer.

"Nothing accessory is required for the complete working of the instrument, with as high a power as a 1-12 Tolles. No reflector is needed, and the amount of light which reaches the eye of the observer is sufficient for critical examination of fine objects with this power. The objective need never be removed from the interior of the tube, nor even touched, except to give place to a second objective. In its place, it is protected from wear and dust, and entirely secluded from a particle of the latter, if the small aperture be plugged with a twisted, small piece of paper. This source of annoyance and trouble, incident to the use of all forms of microscope of the most expensive and elaborate construction, is far more effectually guarded against than by any case.

"In this particular it is preferable to any other form of instrument. It can be as efficiently useful under the most adverse as well as most favorable circumstances. It can even be so used in a railway car in rapid motion. As it rests in or is held by the hand, the coincidence of movement by the car of hand and eye (or head) enables observations to be made with it even here. We cannot imagine any improvement in it. The objectives are of Tolles's best construction of *long focus.* They present a *clear field,* and an image of the object entirely free from coarseness of outline. Unlike any other form of microscope, this can be as advantageously and perhaps more advantageously employed in a reclining posture of the examiner; as, for example, when the head is entirely at rest. Under any circumstances it can be used with the same facility as an opera-glass, and can be used while the observer is in a reclining posture. Even nicer observation can be effected with it in this way than by the ordinary stand microscope; for in this posture of the body, the head being entirely quiescent, there is a perfectly uniform distribution of the fluids of the eye over its entire surface, and an object in the field must be unvaryingly distinct. Held in the hand of the observer, like a common opera-glass, it is equally well used, without any adaptation of the inclination of the body of the observer to the instrument, requiring only the adjustment of it to his eye, whether looking upward or forward.

"But perhaps one of the most original advantages it offers to the observer is, that the object being once on the slide and under observation, it can be manipulated, even to the extent of dissection of it, without transfer. To do this, the observer has only to work with his instruments on the obverse side of the slide. He can thus separate soft solid masses into minuter parts, and subject them during the act to the most careful inspection throughout.

"In these several respects I regard the instrument as combining characteristic advantages over that with the ordinary stand. For clinical observation it will be equally useful."

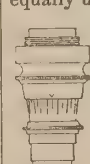

Fig. 2.

Fig. 2 represents an objective of very high power which is used with this instrument, made by the celebrated microscope-maker, Mr. Robert B. Tolles, of this city. It has a novel peculiarity, which will be understood by those who are experts. He calls this feature "immersion without cover." It is used for wet objects. The object is placed on the distal end of the objective itself, and held by placing a cover over it. The light passes through, *first*, the cover, *second*, the object, and then into the objective. In ordinary immersion, the light passes through, *first*, the slide, *second*, the object, *third*, the cover, *fourth*, the immersion liquid, and then into the objective. In the Tolles modification, two media are left out, and the object is viewed directly, with no medium between it and the objective. Used for blood, milk, saliva, and other liquids, denomination of the objection represents 1-12 inch. The adjustment is that of the objective itself.

A SINGULAR ACCIDENT.

Editor Boston Journal of Chemistry: —

Sir: — The following case came within my observation. In December last, Wm. H. Jones, clerk in apothecary store No. 33 Boylston street, Boston, took to his home a tooth-wash composed as follows: —

R Nichols' saturated solution of carbolic acid........ ℥ss.
Essence gaultheria .... ʒi
Aqua fontis.. ℥v
M.

A little sister three (3) years old, got to the bottle, and drank half an ounce of the mixture. She was ill, at the time, of a diarrhœa, (3) three months standing, which had resisted the treatment of three (3) physicians, and growing worse. As soon as it was discovered what the child had done, considerable alarm was excited in the family. This alarm soon subsided when it was discovered no harm followed. But unexpectedly the diarrhœa ceased, and did not return for five weeks, when it was readily checked by a few drachm doses of the same mixture, and is now apparently cured. Yours, etc.,

Ira Perry, M.D.

Boston, Feb. 10, 1869.

Remarks. — This is one of those singular but happy accidents which sometimes occur, and from which much may be learned. It certainly proves, what has been before stated, that carbolic acid exerts a most salutary influence in certain morbid conditions of the bowels attended by obstinate diarrhœa. It is probable, in those troublesome cases of infantile diarrhœa in which the discharges are offensive or putrid, carbolic acid in aqueous solution is the best and most effective remedy. It is to be observed that had the druggist employed the ordinary dangerous concentrated solutions, or the liquid carbolic acid sold by so many druggists, instead of our *saturated aqueous solution,* the child would have been *instantly killed.* Druggists must be careful in what form they dispense this powerful agent.

NOTE FROM DR. CHANNING.

Dr. Nichols: — The following formula combines the action of glycerine, bisulphite of soda, and carbolic acid on the throat better than any which I have seen. I have used it for three years, and recommend it as a gargle or wash in the whole class of inflammations of the throat and mouth to which those reagents apply; especially scarlatina, diphtheria, and croup: —

R Aquæ .... ℥ii.
Glycerine.. ℥i.
Nichols's solution carbolic acid,
Liquor sodæ bisulphite,......................... āā ℥ii.
M.

The formula gives a standard preparation suited to the majority of cases.

Wm. F. Channing, M.D.

Providence, R. I.

THE USES OF WALKING.

Walking, for young and active people, is by far the best exercise; riding is good for the elderly, middle-aged, and invalids. The abuse of these exercises consists in taking them when the system is exhausted more or less by previous fasting or by mental labors. Some persons injudiciously attempt a long walk before breakfast, under the belief that it is conducive to health. Others will get up early to work three hours at some abstruse mental toil. The effect in both instances is the same; it subtracts from the power of exertion in the after part of the day. A short saunter or some light reading before this meal is the best indulgence of the kind; otherwise the waste occasioned by labor must be supplied by nourishment, and the breakfast will necessarily become a heavy meal, and the whole morning's comfort sacrificed by a weight at the chest, from imperfect digestion of food. These observations apply especially to elderly persons, who are prone to flatter themselves into the persuasion that they can use their mental or bodily powers in age as in youth.

BOSTON JOURNAL OF CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. III.—No. 11.] BOSTON, MAY 1, 1869. [FIFTY CENTS PER ANNUM. SINGLE NUMBERS, SIX CENTS.

THE **Boston Journal of Chemistry**

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.

RECEIPTS.—A written receipt will be sent by return mail to all subscribers who will enclose a three-cent P. O. stamp, for return postage.

A list of premiums is offered to those who obtain subscribers.

Familiar Science.

CHEMICAL NAMES.

Every one must see the importance of a systematic nomenclature in a science which, like chemistry, deals with the composition and the classification of all material substances; and few events in the history of chemistry have had a greater influence upon its progress than the adoption of such a nomenclature by the French Academy, in 1787, and its general acceptance by scientific men throughout the world. If we consider merely the tax upon the memory which would be imposed by the multitude of arbitrary names needed to distinguish the ever-increasing list of compounds, we readily see how much is gained by a method of naming which is uniform and systematic. A name like *aqua fortis* (Latin for *strong water*) applies as well to any other powerful acid as to the nitric; and a tyro in chemistry might be puzzled sometimes to connect it with the right one; but the term *nitric acid*, to one who has learned the few fundamental principles of the modern nomenclature, tells at once the story of its composition. So the old name, *sal mirabile* (or *wonderful salt*), which was given to what is otherwise known as *Glauber's salt*, is unmeaning and unsuggestive; while *sulphate of soda*, or the more recent *sodic sulphate*, cannot be misunderstood or misinterpreted.

It is not our purpose to give the history or to state the laws of the chemical nomenclature which has been in general use for many years. These can be found in any of the elementary books on chemistry, and are doubtless familiar to the great majority of our readers. We wish merely to say a few words about the more important *modifications* of this nomenclature, which are now adopted by the leading writers on chemistry, both in England and in this country. In the *Handbook of Chemistry*, by Messrs. Rolfe and Gillet, we are pleased to find the new nomenclature adopted. It is also found in Roscoe's *Elementary Treatise*, which we recently noticed.

It is a singular fact that the main features of this new nomenclature are *not* new, but were proposed by Berzelius half a century ago. Such terms as *ferrous oxide* and *ferric oxide*, *ferrous sulphate* and *ferric sulphate*, which many imagine to be the invention of the more progressive of living chemists, were first used and advocated by him. It is strange that they were not at once accepted generally; for they are briefer, more expressive, and more in harmony with the fundamental principles of the prevailing system than the names based upon that system. *Nitrous* and *nitric*, *sulphurous* and *sulphuric*, and the like, have become familiar as expressing different degrees of oxidation in the case of the *acids*; and Berzelius wished to apply the same principle of naming to the *bases* and *salts*. *Ferrous oxide* is more concise than *protoxide of iron*, and *ferric oxide* than *sesquioxide of iron*; and *ferrous sulphate* is, for the same reason, better than *protosulphate of iron*, and *ferric sulphate* than *sesquisulphate of iron.* Moreover, as the names *ferrous* and *ferric* are derived from the Latin, they will have essentially the same forms in all the modern languages; and an approach is thus made to a universal chemical nomenclature. The advantage of such uniformity of usage in different countries is not slight in these days, when every student of chemistry must be familiar with French and German works which are not translated into English, and when so many English and Americans are pursuing their studies at Berlin, Gottingen, Heidelberg, and Paris.

Under this new Berzelian method, the names of *all* binary compounds are formed, in the same way, from the names of their constituents; the name of the electro-positive constituent, with the ending *ic*, being placed before that of the electro-negative constituent, which is made to end in *ide*. Thus, potassium and sulphur form *potassic sulphide* (formerly *sulphide of potassium*, and, at an earlier day, *sulphuret of potassium*); sodium and oxygen form *sodic oxide* (formerly *soda* or *oxide of sodium*); silver and chlorine form *argentic chloride* (*chloride of silver*); lead and iodine, *plumbic iodide* (*iodide of lead*); and so on. When the same elements form two compounds, the one containing the *smaller* proportion of the negative element is distinguished by changing the ending of the name of its positive constituent to *ous*; the ending *ic* being used for the compound containing the *larger* proportion of the negative element. This is illustrated by the names *ferrous oxide* and *ferric oxide*, of which we have spoken above. In the same way, we have *mercurous* and *mercuric* oxides, *cuprous* and *cupric* oxides (oxides of *copper*), *stannous* and *stannic* chlorides (chlorides of *tin*), etc. Calomel is *mercurous chloride*, and corrosive sublimate is *mercuric chloride*; and so on. The Latin adjectives can cause no trouble to the student of chemistry, who has already learned that the symbol of iron is Fe, from *ferrum*; that of tin, Sn, from *stannum*; etc.

When a binary compound contains oxygen, and becomes an acid when united with water, or a salt when united with a base, it is termed an *anhydride*. Thus, one atom of oxygen and two of sulphur form *sulphurous anhydride* (formerly *sulphurous acid*); one of oxygen and three of sulphur, *sulphuric anhydride* (*sulphuric acid*). The old names are given to the *true* acids, or the compounds of these anhydrides with water. There is here also a gain in clearness and conciseness, compared with the old way of naming. We no longer need use the absurd name, *anhydrous sulphuric acid*, to describe a substance which has no acid properties whatever; and when we speak of sulphuric *acid*, there can be no doubt which of the two compounds is meant.

The *hydrogen* acids, or *hydracids*, are named in the same way as other binary compounds. Thus, muriatic acid is *hydric chloride*; hydrosulphuric acid (or *sulphuretted hydrogen*, or *sulphide of hydrogen*, or whatever it may have been called) becomes *hydric sulphide*; and so on Of course, in the case of these and many other very familiar substances the common or *trivial* name is often

used. We should not generally speak of water as *hydric oxide*, any more than we used to call it *protoxide of hydrogen*.

We hardly need go on to explain the naming of the *salts*, which is on the same general principle, and which we have already illustrated in the case of *ferrous sulphate* and *ferric sulphate*. The reader will have no difficulty in applying the rule for naming *binary* compounds to the interpretation of the names of *ternary* compounds; such as *argentic nitrate, sodic phosphate, calcic carbonate* (carbonate of lime), *plumbic chromate*, etc.

It would exceed our present limits, and it was not our purpose, to give the minor points in the new system, or to show its application to the naming of organic compounds.

We will only add that this nomenclature has been adopted by the Chemical Society of London, and is coming to be generally used by the best modern authorities. Some recent writers have accepted, thus far, only a portion of the system; but consistency and the force of the current will doubtless soon compel them to adopt it in full. A man who persists in speaking of "lead nitrate" and "sodium sulphate," while he does not hesitate to say "ferrous sulphate" and "ferric sulphate," is pretty certain eventually to exchange his mixed nomenclature for a uniform one.

"HUMBUG" TOADS.

A correspondent of the *London Mining Journal* thus disposes of the hermetically sealed toad business. He says,—"Your Derbyshire correspondent, in last week's *Journal*, refers to the alleged discovery of a live toad in a solid block of Cannel at the Ravenhead Colliery, St. Helen's. This to me is like all other fabulous reports. I would first ask if the man is one of those who get an extra shilling by such tricks; for it looks much like a trick, when he says his attention was called to the fine appearance of the piece of coal. He then broke it, and found it hollow, and then takes it with him to the surface, and finds a toad in it. It is not unusual to find stones hollow. Then what could have induced him to carry it to the surface. I have myself twice had this attempted to be practised on me. Hollow stones are very convenient to play this trick with. I have seen frogs put in a hole not half the size of a frog's body. I was in Wales a few months since, where some men were sinking a shaft, half in solid rock and half in old quartz. There were four Scotch gentlemen with me. The men blasted a hole, and in a few moments one of the men came up with a living frog, and said the hole had thrown it out. The Scotch gentlemen were so delighted with the discovery that orders were given for something to be got to convey it to Scotland, and the man was about to get a reward, when I interfered, and asked them if half the shaft was not in old rubbage. I had seen it, and they were compelled to acknowledge it, as Mr. Mackenzie, the engineer, was one of the party, and would have gone down and proved it. The smoke of the powder soon caused the frogs near to get out of the water, and this one jumped up on the rock. Miners now a days are quite up to all these manœuvres to get a ready shilling. I thought to have heard no more of frogs or toads in stones after what Mr. Hunt openly stated as to himself and all the committee at the Exhibition being misled, when they allowed the frog to be put in the lump of coal there as being found in a lump of coal in a mine. Mr. Hunt stated at a public meeting that they were duped, and he much regretted ever consenting to it being put there. It is only narrow-minded men who allow rogues to dupe them in such a way."

A PHYSICIAN'S EVIDENCE ON DANCING.

That beautiful, graceful accomplishment of dancing, so perverted by late hours and the indecency of fashionable attire, has outraged many sensible people, and led them to deprive the young ones of the most simple and healthful enjoyments, because it has been abused. For myself, I can testify not only to its healthful, but recuperative power. The fortieth, nay, the fiftieth year of my age found me enjoying this life-cheering exercise. It should be one of the earliest amusements of children, and care should be taken by parents that it is understood as an amusement. While I am on this topic, I will mention a case that occurred in my practice. A thoughtful, anxious mother, who had lost three children, brought to me her only remaining child, a daughter. Her temperament nervous, billious,—the nervous fearfully predominant,—with great irritability of the system; peevish, passionate, dyspeptic, sleepless; of course exacting, arbitrary, and uncomfortable, the poor child looked sad, old, morbid, and miserable. She had been to school, because her parents thought it an amusement for her to be with other children. After critically examining her physiognomy, I said to her mother, "What is the temperament of your husband?" "The same as my own," she replied. "Then the child is doubly stamped," I continued. Very vigorous measures must be used, if you expect to restore her to health. Divorce her immediately from anything mental, so far as memorizing is concerned; then send her to dancing-school, that she may combine exercise with order and melody, and thus some of her rough edges may be rounded." The child, her large eyes open with wonder and delight, interrupted with, "Dancing-school? Oh, how I've longed to go! but mother says its wrong, and leads to wickedness." What a dilemma for a physician! what a dilemma for a child! "Did you ever intend your daughter to play the piano, guitar, or other musical instrument?" said I, to the mother. "Oh, yes," was the answer. "Why," I continued, "why show such partiality to the upper extremities? The hands are rendered happy as a medium of melody; the feet are rendered equally happy in the same way."

A nice afternoon school revived the little girl, who grew in health and harmony every month, as she followed the hygienic rules prescribed for her. Dancing is a healthful, beautiful, graceful recreation, and is not responsible for the abuses luxury has thrown around it. The vulgarism and excitements of the ball-room have no more to do with the simple enjoyment of the dance than the rich wines and sumptuous banquets of the gourmand, in whom they induce disease, have to do with the temperate repasts that satisfy the natural wants of the body.

DR. H. K. HUNT.

CHELSEA, Feb. 11, 1869.

HEAT AND FORCE.

Whenever friction is overcome, heat is produced; and the amount of heat so produced is the exact measure of the force expended in overcoming the friction. Professor Tyndall says, while speaking upon the subject of "Heat Considered as a Mode of Motion,"—"We usually put oil upon the surface of a hone; we grease the saw, and are careful to lubricate the axles of our railway carriages. What are we really doing in these cases? Let us get general notions first; we shall come to particulars afterwards. It is the object of the railway engineer to urge his train boldly from one place to another. He wishes to apply the force of his steam or his furnace, which gives tension to the steam to this particular purpose. It is not his interest to allow any portion of that force to be converted into another form of force, which would not further the attainment of his object. He does not want his axles heated, and thence he avoids as much as possible expending his power in heating them. In fact he has obtained his force from heat, and it is not his object to reconvert the force thus obtained into its primitive form. For by every degree of temperature generated by the friction of his axle, a definite amount would be withdrawn from the urging force of his engine. There is no force lost absolutely. Could we gather up all the heat generated by the friction, and could we apply it mechanically, we should by it be able to impart to the train the precise amount of speed which it lost by the friction. Thus every one of those railway porters whom you see moving about with his can of yellow grease, and opening the little boxes which surround the carriage axles, is, without knowing it, illustrating a principle which forms the very solder of Nature. In so doing he is unconsciously affirming both the convertibility and the indestructibility of force. He is practically asserting that mechanical energy may be converted into heat, and that when so converted it cannot still exist as mechanical energy, but that for every degree of heat developed a strict and proportional equivalent of locomotive force of the engine disappears. A station is approached, say at the rate of thirty or forty miles an hour; the brake is applied, and smoke and sparks issue from the wheel on which it presses. The train is brought to rest. How? Simply by converting the entire moving force which it possessed at the moment the brake was applied into heat."

LIFE LENGTHENED.

1. Cultivate an equable temper; many a man has fallen dead in a fit of passion.

2. Eat regularly, not over thrice a day, and nothing between meals.

3. Go to bed at regular hours. Get up as soon as you wake of yourself, and do not sleep in the daytime, at least not longer than ten minutes before noon.

4. Work always by the day, and not by the job.

5. Stop working before you are very much tired,—before you are "fagged out."

6. Cultivate a generous and an accommodating temper.

7. Never cross a bridge before you come to it; this will save half the troubles of life.

8. Never eat when you are not hungry, nor drink when you are not thirsty.

9. Let your appetite always come uninvited.

10. Cool off in a place greatly warmer than the one in which you have been exercising; this simple rule would prevent incalculable sickness, and save millions of lives every year.

11. Never resist a call of nature for a single moment.

12. Never allow yourself to be chilled "through and through;" it is this which destroys so many every year, in a few days' sickness, from pneumonia, called, by some, lung fever or inflammation of the lungs.

13. Whoever drinks no liquids at meals will add years of pleasurable existence to his life. Of cold or warm drinks, the former are most pernicious; drinking at meals induces persons to eat more than they otherwise would, as any one can verify by experiment; and it is excess in eating which devastates the land with sickness, suffering, and death.

14. After fifty years of age, if not a day laborer, and sedentary persons after forty, should eat but twice a day, in the morning and about four in the afternoon; persons can soon accustom themselves to a seven-hour interval between eating, thus giving the stomach rest; for every organ without adequate rest will "give out" prematurely.—*Hall's Journal of Health.*

USEFUL REMEDIES.

Editor Boston Journal of Chemistry:—

Will you permit a non-medical correspondent to suggest two or three simple remedies for "ills that flesh is heir to," or to which it is frequently exposed?

CHILBLAINS.—Some persons are constitutionally exposed to these troublesome and sometimes painful things. Ordinarily they are developed as a consequence of cold feet; though there are individuals so sensitive that the appearance of snow in the atmosphere is sufficient to bring on the difficulty.

In cases where the irritation and swelling have not resulted in ulceration or abrasion of the skin, soak the foot in tepid water about ten minutes, just before going to bed. Wipe the foot dry, and immediately anoint the part affected with pure *oil of cloves*. Cover it with a piece of oil silk, or the film taken from "leaf lard" or suet; draw on a cotton stocking for the night; and, ordinarily, the soreness and irritation will have disappeared by the next morning. If one application is not fully successful, try it again the night following, and repeat as often as the chilblains appear. This remedy has been employed by the writer during twenty years, and has never failed to afford the desired relief.

BURNS.—The success of this application in the case of chilblains (which so strongly resemble slight burns), led to a trial of its virtues in the latter instance; and the success was such that it has been frequently repeated in the writer's family for the last fifteen years; and many a time have children and *cooks* had reason to be thankful for the relief afforded.

We ordinarily keep some oil of cloves (renewing it each year) in a vial, with a small quill or camel's hair

pencil stuck in the cork, and immersed in the oil. In the case of a burn or scald *which is not so severe as to break the skin*, apply the oil of cloves immediately. If this is done before the blister appears, it will be effectually prevented, and the pain will be allayed. If the blister is produced, the pain will, nevertheless, be speedily relieved; and, as the irritation will also be removed, the blister will not cause much inconvenience.

The writer wishes to have it distinctly understood that this remedy is proposed for slight burns and scalds only where the skin is unbroken. Were the injury *severe*, *i.e.*, extensive, or if excoriation had taken place, he would call in a physician, and commit the case to his hands.

Cold Sores.—This name is commonly given to the small blisters or ulcers which frequently form on the edges of the lips and nose when one has taken cold. They may be entirely *prevented* by frequently applying *strong spirits of camphor* to the part affected, as soon as the irritation appears; and if the blister is developed, the same remedy will remove all soreness and irritation in the course of twelve or twenty-four hours. S.

Arts.

CHEMISTRY OF HAIR DYES.

The attention which we called, some time since, to the new and perfect black hair dye which Dr. M'Call Anderson lately incidentally hit upon, produced a long series of commentaries from accomplished dermatologists and others well qualified to speak on the not uninteresting subject. Mr. Erasmus Wilson, a leader amongst the professors of dermatology, now enters upon and discusses the whole question in a series of very interesting observations in the *Journal of Cutaneous Medicine*. He observes, that the hair owes its property of dyeing to its porosity, which is evidently greater than its physiological structure would lead us to infer. Another of its properties, namely, the presence of sulphur in its constitution, renders it prone to darken under the use of certain mineral substances; for example, lead and mercury, whose compounds with sulphur are black. Thus, if a weak solution of lead or mercury be brushed into the hair, a certain quantity of the solution will penetrate the hair, and a dark color will be produced in consequence of the formation of a sulphuret of lead or sulphuret of mercury. The depth of the shade of color will depend upon the quantity of sulphur present in the hair; and as red hair and light colored hair contain more sulphur than dark hair, the result will in that case be comparatively greater. But where the amount of sulphur is too minute to produce the dye, science suggests the means of introducing more sulphur, as is illustrated by a reversal of the process, in the following quotation from a paper by Dr. M'Call Anderson, on *Eczema Marginatum*:—

"During the treatment I accidentally discovered what promises to be the most perfect black dye for the hair which has been seen. After having used the bichloride lotion for some weeks, I changed it for the lotion of hyposulphite of soda, and the morning after the first application the hair of the part which before was bright red had become nearly black. One or two more applications rendered it jet black, while neither the skin nor the clothing were stained. I saw this patient a couple of weeks later, and there was not the least deterioration of color, although, of course, as the hair grows the new portions will possess the normal tint."

The reason of the escape of the epidermis while the hair was so thoroughly dyed is that it contains no sulphur. Mr. Balmanno Squire, in a commentary on the above process, observes, that if, instead of the hyposulphite of soda, one of the more common mordants be employed,—say, for example, the sulphide of ammonium,—instead of a black, a bright red color will result. The *modus operandi* of Dr. Anderson's dye is this. The hypo-sulphurous acid, on being liberated from the soda, decomposes into sulphurous acid and sulphur. The sulphurous acid reduces the bichloride of mercury to the chloride, and the sulphur converts the chloride into (black) sulphide. The effect of the sulphide of ammonium on bichloride of mercury is to produce the (red) bisulphide which is the common vermilion of commerce. Another commentator on hair dyes observes, that with the barbers the sheet anchor appears to be lead and lime. And again, it is recommended to first wash the hair with a solution (ten grains to the ounce) of nitrate of silver; then use a weak solution of pyrogallic acid, and wash.

An interesting article on the subject, from the pen of an able chemical writer, Dr. Scoffern, may be found in the May number of *Belgravia*, under the head of "Cosmetics for the Hair." Dr. Scoffern reminds us that the Persians employ indigo to procure a blue-black dye, and the Turks and Egyptians a pasty writing ink, composed of pyrogallic acid in combination with a native ore of iron, while in the West the chief constituents of hair dyes are metallic bodies and walnut juice. The metals chiefly in use as capillary chromatics are silver, lead, and arsenic, while others applicable to a similar purpose are gold, bismuth, iron, copper, cadmium, titanium, uranium, and molybdenum. Lead in its crudest form is represented by the leaden comb; but as the process by this means is slow, a compound of oxide of lead, or litharge, with lime, and made into a paste with water, is more commonly employed. This is smeared on the hair at night, the evolved gases being imprisoned by an oil-silk cap, and in the morning the dried paste is brushed out and the hair refreshed with pomatum. Or if a so-called brown, a smothered or fusty black be required, the paste should be mixed with milk instead of water. The night is preferable for these remedies, because the hair is supposed to exhale more sulphur at this period than during the day. These preparations remind us of a lotion in common use at the present time, consisting of a drachm of acetate of lead, with twice the quantity of sulphur, to half a pint of water. The nitrate of silver is another common form of dye, but is open to the objection of staining the skin and, in fact, everything it touches, and also of becoming iridescent on exposure to light, producing, as Dr. Scoffern observes, a chromatic play of tints, which is very undesirable. Bismuth presents the same characteristics as lead, but is not much used; and when iron is employed to produce a black tint, it requires for its mordants either the pyrogallic acid or the hydrosulphate of ammonia. Brown is produced by the chloride of gold alone, as also by a solution of sulphate of copper with a mordant of the prussiate of potash (ferrocyanide of potassium); and titanium, uranium, and molybdenum, judged by their chemical behavior, would give rise to similar results. The golden yellow color, so much in fashion of late, is produced by a solution of arsenic with a mordant of the hydrosulphate of ammonia. And cadmium would probably give rise to a similar result. In the case of dyeing the lighter tints, however, it becomes necessary to submit the hair to a process of bleaching, which is commonly effected by a solution of one or other of the alkalies; by chlorine, by the chloride of soda or lime, or by sulphurous acid, bisulphate of magnesia or lime, or peroxide of hydrogen. In general, the dyes requiring mordants do not stain the epidermis. —*British Medical Journal.*

ABOUT COFFEE.

If the raw berries are boiled in water, from 23 to 24 per cent of the soluble matter is extracted. On being roasted till they assume a pale-chestnut color, they lose 15 to 16 per cent, and the extract obtained from these by means of boiling water is 20 to 21 per cent of the weight of the unroasted berries. The loss in weight of the extract is much larger when the roasting process is carried on till the color of the berries is dark brown or black. At the same time that the berries lose in weight by roasting they gain in volume by swelling; 100 volumes of green berries give, after roasting, a volume of 150 to 160; or two pint measures of unroasted berries give three pints when roasted.

The usual methods of preparing coffee are, 1st, by filtration; 2d, by infusion; 3d, by boiling.

Filtration gives often, but not always, a good cup of coffee. When the pouring of the boiling water over the ground coffee is done slowly, the drops in passing come in contact with too much air, whose oxygen works a change in the aromatic particles, and often destroys them entirely. The extraction, moreover, is incomplete. Instead of 20 to 21 per cent, the water dissolves only 11 to 15 per cent, and 7 to 10 per cent is lost.

Infusion is accomplished by making the water boil, and then putting in the ground coffee; the vessel being immediately taken off the fire and allowed to stand quietly for ten minutes. The coffee is ready for use when the powder swimming on the surface falls to the bottom on slightly stirring it. This method gives a very aromatic coffee, but one containing little extract.

Boiling, as is the custom in the East, yields excellent coffee. The powder is put on the fire in cold water, which is allowed merely to boil up for a few seconds. The fine particles of coffee are drank with the beverage. If boiled long, the aromatic parts are volatilized, and the coffee is then rich in extract, but poor in aroma

As the best method, I adopt the following, which is a union of the second and third:—

The usual quantities both of coffee and water are to be retained; a tin measure, containing half an ounce of green berries, when filled with roasted ones, is generally sufficient for two small cups of coffee of moderate strength, or one so called large breakfast cup (one pound of green berries, equal to sixteen ounces, yielding after roasting 24 tin measures [of one-half ounce] for 48 small cups of coffee).

With three fourths of the coffee to be employed, after being ground, the water is made to boil ten or fifteen minutes. The one quarter of the coffee which has been kept back is then flung in, and the vessel immediately withdrawn from the fire, covered over, and allowed to stand for five or six minutes. In order that the powder on the surface may fall to the bottom, it is stirred round; the deposit takes place, and the coffee poured off is ready for use. In order to separate the dregs more completely, the coffee may be passed through a clean cloth; but generally this is not necessary, and often prejudicial to the pure flavor of the beverage.

The first boiling gives the strength, the second addition the flavor. The water does not dissolve of the aromatic substances more than the fourth part contained in the roasted coffee.

The beverage when ready ought to be of a brown-black color; untransparent it always is, somewhat like chocolate thinned with water; and this want of clearness in coffee so prepared does not come from the fine grounds, but from a peculiar fat resembling butter, about twelve per cent of which the berries contain, and which, if over roasted, is partly destroyed.

In the other methods of making coffee, more than the half of the valuable parts of the berries remains in the "grounds," and is lost.

To judge as favorably of my coffee as I do myself, its taste is not to be compared with that of the ordinary beverage, but rather the good effects might be taken into consideration which my coffee has on the organism. Many persons, too, who connect the idea of strength or concentration with a dark or black color, fancy my coffee to be thin and weak, but these were at once inclined more favorably directly I gave it a dark color by means of burnt sugar, or by adding some substitute.

The real flavor of coffee is so little known to most persons that many who drank my coffee for the first time doubted of its goodness, because it tasted of the berries. A coffee, however, which has not the flavor of the berry is no coffee, but an artificial beverage, for which many other things may be substituted at pleasure. Hence it comes that if to the decoction made from roasted chicory, carrots, beetroot, the slightest quantity of coffee be added, few persons detect the difference. This accounts for the great diffusion of each such substitute. A dark mixture, with an empyreumatical taste, most people fancy to be coffee. For tea there are no substitutes, because every body knows what real tea is like.—*Liebig.*

GAS FOR FUEL.

Editor Boston Journal of Chemistry:—

I observe in the papers an extract from your *Journal* predicting the progress that will be made in the year 1900. Among other things, you predict that we will dispense with coal and wood as a source of heat, but use, instead, a cheap gas. This desideratum will be realized more speedily than you conjecture. I have now in the Patent Office my specifications for the production of "steam gas" from water, not by the costly retort method, but by means of a furnace, whereby I can get the mixture of carbonic oxide and hydrogen at a mere nominal cost. I do not think this steam gas will cost over ten or fifteen

cents the thousand cubic feet. This new illuminating gas gives a powerful heat, but of course but little light. To render it light-giving, I pass it through a light hydrocarbon, by which it acquires an illuminating power of about fifty per cent over coal gas. Thus, I say, your prediction will be fulfilled ere the year 1900 comes!

The gases, being inflammable ones, do not appear to merely mix with the vapor of the hydrocarbon, but they unite themselves with it by such a powerful affinity that a very reduced temperature is required to condense out this hydrocarbon. But the great value of the steam gas will no doubt be its great adaptability to heating purposes, being, as it is, so cheaply made. As you appear to think, the world has to come to this method of heating, and the sooner the better. Then, indeed, will we have as you say, "no ashes, no smoke, no dust;" but all will be comfort, safety, and convenience.

Respectfully,

J. Milton Saunders.

New York, March 24, 1869.

Remarks.—We print Prof. Saunders' note with pleasure, as he has a deservedly high reputation as a chemist. We must be permitted to doubt, however, regarding the full practical success of his invention. Probably no party in this country has experimented more carefully or persistently in this direction than we have, and we certainly ought to possess a pretty clear understanding of the obstacles to be overcome in reaching such results. We are far from regarding them as impossible; but they are too important to be attained at a single bound. If Prof. Saunders can give us hydrogen, or a mixture of hydrogen and carbonic oxide, at ten or fifteen cents the thousand cubic feet, in unlimited quantities, he must be regarded as not only a very great discoverer, but benefactor of the race. We shall look with interest to his more mature conclusions or views regarding the matter.

Dr. Cutter's Clinical Microscope.—We are requested by Dr. Cutter to say, that the Clinical Microscopes described in the April *Journal* are not yet in the market. Owing to high cost of skilled labor in this country, they can be made much cheaper at Paris than here. But in order to obtain them at the lowest possible price, it is necessary to have made not less than fifty at one time. As soon as the requisite number is engaged, at a price not to exceed twenty-five dollars each, they will be ordered. Physicians wishing them will please send in their names to Mr. George S. Chase, at the office of the *Journal of Chemistry*. The money need not be paid until the arrival of the instruments.

Dr. C. has recently mounted his microscope upon a stand, thus making it in every way equal to a microscope of a much higher price, while not interfering with its peculiar value as a clinical or pocket instrument.

Popular Errors.—To think that the more a man eats the fatter and stronger he will become. To believe that the more hours children study the faster they learn. To conclude that, if exercise is good, the more violent it is the more good is done. To imagine that every hour taken from sleep is an hour gained. To act on the presumption that the smallest room in the house is large enough to sleep in. To argue that whatever remedy causes one to feel immediately better is good for the system, without regard to more ulterior effects. To eat without an appetite; or to continue to eat after it has been satisfied, merely to gratify the taste. To eat a hearty supper for the pleasure experienced during the brief time it is passing down the throat, at the expense of a whole night of disturbed sleep, and a weary waking in the morning.

Composition of Lucifer Matches.—Phosphorus, 4 parts; nitre, 10; fine glue, 6; red ochre, or red lead, 5; smalt, 2; convert the glue with a little water, by a gentle heat, into a smooth jelly, put it into a slightly warm porcelain mortar to liquefy; rub the phosphorus down through this gelatin at a temperature of about 140° or 150° Fah.; add the nitre, then the red led, and lastly the smalt, till the whole forms a uniform paste.

Agriculture.

SOUTHERN AGRICULTURE.

The energy and industry displayed by the people of the Southern States, in labor upon the land and in the workshop, is worthy of the highest praise. The sufferings and losses experienced by the terrible war were such as but few people have ever been called upon to endure. It is evident, however, they are not disheartened; but still resolute and hopeful, and determined to be again prosperous. A more generous or a kinder people cannot be found in any country upon the earth; and Northern men who have gone among them are loud in their praise of the courteous and friendly manner with which they are received. The lands of the Southern States are, for the most part, very fertile, and the genial climate is in marked contrast with the frigid, icy winters of the North. There is ample room for Northern farmers in the Gulf States, and in the raising of cotton, the cereal grains, and fruits there is great profit.

Lands can be bought at low prices at present in Alabama, Tennessee, Georgia, and the adjoining States, and no man who respects himself, and is worthy of the good will and respect of others, need have the least fear of meeting with other than the most pleasant treatment from Southern men and women. Fractious, meddlesome, gossipping individuals, who cannot live on good terms with their neighbors here, had better not migrate; but we fully believe, from what we know of the South, and from letters received from various sections, that fair minded, industrious farmers can greatly improve their condition by purchasing lands and locating in some of the Middle or Southern States. The northern part of Alabama, in the Valley of the Tennessee, would suit us better than any locality, as the climate is genial and healthy, and the land extremely fertile. The time is coming when that beautiful valley is to be the garden of the world, and filled with a dense population.

ERRONEOUS VIEWS.

In some remarks made by Col. Daniel Needham, in the Massachusetts Senate, upon the bill relating to the sale of commercial fertilizers, he gave a formula for preparing a fertilizer which was presented as something new and valuable. He is reported as making the following statements:—

"He said that a most valuable fertilizer could be made by taking four barrels of ground bone, one carboy of sulphuric acid, and two barrels of ashes. He said that the expense of this fertilizer would be only about eighteen dollars a ton, and that he did not doubt the fertilizer thus made would be as valuable as any purchased in the market for forty dollars per ton. He stated the expense substantially as follows:—

4 barrels bone, at $2.50 per barrel,	$10 00
175 pounds sulphuric acid,	5 25
2 barrels ashes,	2 50
	$17 75

"The process of mixing, he said, was very simple. He would take the ground bone, and, after wetting it thoroughly, allow it to heat, which it would do in a short time; then pour on the sulphuric acid, and afterwards mix with the mass two barrels of ashes."

Quite a number of correspondents have inclosed to us slips cut from newspapers containing the formula, with requests for an expression of opinion in the *Journal* respecting its value. As regards this matter it may be said in brief, that we have a very high opinion of the substances employed, but a very poor opinion of the chemistry involved in making up the mixture. It is proposed to do first simply what we have so often recommended farmers to do,—make their own superphosphate, by acting upon ground bones with sulphuric acid. But that also is proposed, which we have never recommended,—viz., add ashes to the mixture, and thus greatly retard or injure the fertilizing influence of both the superphosphate and the ashes.

Ashes contain much caustic potash and soda, and these would be instantly seized upon by the free phosphoric acid in the dissolved bone, and locked up in new combinations,—phosphate of potash and soda. Thus several agents, of high fertilizing value as they exist in the bone mixture and naturally in the ashes, would be placed in a form not so readily and perfectly assimilable by plants.

The mixture is quite unscientific and unnecessary, and farmers had better keep ashes out of their superphosphate; for, as chemists say, it is incompatible. Adding ashes to fine bone, moistened with water, as we have recommended, gives quite different results. The caustic alkalies act upon the gelatine or the animal portion of the bone, and become in part saponified; and by abstracting or appropriating this portion of the bony structure the atoms of phosphate of lime are liberated and made ready for plant food. The soapy, alkaline portion goes to form a healthy, robust stalk; the phosphoric acid and lime gives full, plump seeds.

It may be further remarked, regarding the fertilizer spoken of above, that the prices affixed to the substances are as far from being correct as the formula. The cost of the mixture would be nearly double the price stated.

ABOUT CROWS.

The following extract is taken from an article in the April number of the *Atlantic Monthly*, written by Thos. M. Brewer:—

"Whatever wrong the crow commits against the cultivators of the soil, may, by a little painstaking, be materially lessened or wholly prevented. The benefits he confers are both numerous and important. 'During the time he remains with us, he destroys,' says no less authority than Wilson, 'myriads of worms, moles, mice, caterpillars, grubs, and beetles.' Audubon also affirms that the crow devours myriads of grubs, every day of the year,—grubs which would lay waste the farmer's fields,—and destroys quadrupeds innumerable, every one of which is an enemy to his poultry and his flocks. Dr. Harris, also, one of the most faithful and accurate observers, in speaking of the fearful ravages sometimes wrought in our grass lands and gardens by the grub of the May beetles, adds his testimony to the great services rendered by the crow in keeping these pests in check. Yet in Massachusetts, regardless of such testimony in their favor, we have nearly exterminated these birds; and the destructive grubs, having no longer this active enemy to restrict their growth, are year by year increasing with a fearful persistence. We have seen large farms, within an hour's ride of Boston, in which, over entire acres, the grass was so completely undermined, and the roots eaten away, that the loosened turf could be rolled up as easily as if it had been cut by the turfing spade. In the same neighborhood, whole fields of corn, potatoes, and almost every kind of garden vegetables had been eaten at the root, and destroyed. Our more intelligent farmers, who have carefully studied out the cause of this unusual insect growth, have satisfied themselves that it is the legitimate result, the natural and inevitable consequence, of our own acts. Our shortsighted and murderous warfare upon the crow has interrupted the harmonies of nature, disturbed her well-adjusted balance, and let loose upon agriculture its enemies, with no adequate means of arresting their general increase."

The reverse is true of nearly or quite all the statements contained in this extract. Notwithstanding Audubon or Mr. Harris, we do not believe the crow confers benefits

upon farmers or any one else. It is positive, he is a saucy, prowling, mischievous bird. Crows never were so numerous in New England as at the present time. They are increasing with great rapidity. We have seen, the present winter, flocks of them containing thousands. On one of our wheat-fields, the past summer, a black cloud of crows embracing several hundred settled down, and tore up the tender roots of the sprouting grain to a great extent. The crow does not often alight in fields to destroy "grubs, beetles, and caterpillars." Unless there is a corn or wheat field to ravage, they remain most of the time in the woods, out of harm's way.

If Mr. Thos. M. Brewer had not given us the results of his observations upon fields "within an hour's ride of Boston," we should have concluded, from his absurd statements, that he never was in the country so far from the State House.

As regards "our shortsighted and murderous warfare upon crows," we venture to inquire what is meant by this. The crow is so "longsighted" that farmers' boys and others intent upon "murderous warfare," cannot well get near them to commit half enough "murders." This cunning, sagacious bird knows so well how to take care of himself, it is quite unnecessary for our city philanthropists to get up laws for their protection; and we beg of Mr. Brewer that he will turn his attention to some other department of philanthropy or philosophical inquiry.

GRAPE CULTURE.

The cultivation of the grape is so easy and simple, that it seems strange that any family having a house and lot, however small, should neglect the culture of a fruit so beautiful and so much of a luxury as is the grape. In every yard, both in city and country, where the sun reaches the earth, and where there is room on house, fence, stake, or trellis, for the vine to be trained, there a vine should be planted.

The first thing to be done is to prepare the ground for the reception of the roots. If only one is to be planted, dig out a hole four feet square and two feet deep, and fill it with good rich soil mixed with one third as much old, well-rotted manure; and then plant your vine, spreading the roots evenly in every direction, and cover about four inches deep.

The most important part of grape culture is the training and pruning. No cultivated variety will continue to produce a good crop of fine, well-ripened fruit, unless it be wisely pruned. There are a number of modes of training vines which are good; but the most simple and easily managed plan is that by which the vine is trained with horizontal arms. To grow a vine in this form, commence by growing one cane on an upright stake, pinching off the little side branches, or laterals, leaving one leaf. This pinching is to be repeated when the laterals grow again, and an additional leaf is left at each successive pinching. This treatment concentrates the sap in the main stalk, which should be grown as large and strong as possible, the first season; and the end should be pinched off before cold weather sets in.

In February, this shoot should be cut down to the point where the arms are to start from, say fifteen to eighteen inches from the ground. Then rub off all the buds below the two upper ones, and from these two buds grow two new stalks, as nearly opposite as possible, and in the direction in which you wish to have them when placed in a horizontal position; but grow them nearly upright during the season, and treat them with as much care as was the one during the former season. The third year, in February, these two canes are to be cut off to about four feet above where they were the year before. Then bend them down to a level position, one to the right and the other to the left, and fasten them to the trellis with a strip of leather. The trellis should be prepared before the third year.

Next, cut out, or rub off after they start, all the buds on the under side of these arms, which will be every other bud. The upper bud will grow, and produce canes that will produce bunches of grapes this season; but only a few should be allowed to grow, as it will exhaust the root.

With short-jointed varieties, like the Delaware, it will sometimes be necessary to take off a part of the buds on the upper side of the arm; or the fruit-bearing canes will be too close together. But with long-jointed varieties, like the Concord or Diana, this will not be necessary, as every alternate bud will bring the bunches from eight to twelve inches apart.

When these canes have grown up to twenty inches or two feet, the tops should be pinched off, so as to check their growth; and when they have grown two or three inches more, pinch again. This pinching has a tendency to expand the leaves, to ripen the wood, and to increase the size of the fruit.

The fourth year, these fruiting canes are to be cut down to one good strong bud near the arm; and from this bud another fruiting cane is to be grown, the same as the year previous. The vine may now be considered fully established; and the same process is to be repeated from year to year, unless it is desirable that the vine should cover a large space. In that case, bend down the cane nearest the end of the arm, and extend it in the same way you did the arm in the beginning.

DISSOLVING BONES.

We suppose as acceptable and useful service can be done our agricultural readers in pointing out the errors into which they are liable to fall, and warning them against the expensive and profitless experiments they may be led to undertake, as in stating new facts, or calling attention to new and important discoveries. They are constantly liable to be misled by the statements made at farmers' club-meetings and through the journals professedly devoted to their interests. We have recently read, in one of the most widely circulated of our agricultural papers, an editorial article upon dissolving bones in sulphuric acid, in which farmers are advised to collect large quantities of bones, reduce them to fragments by pounding, and then dissolve them by pouring on the acid. Also the same wise advice was given by several speakers, at a recent meeting of the New York Farmers' Club. Now, this is all wrong. Farmers should not be advised to treat bones in this way, as it will certainly end in disappointment and pecuniary loss. Raw bones pounded into fragments cannot be fully and expeditiously dissolved in acid; and whoever recommends the process has never tried the experiment, or if he has he purposely misleads. Fragments of bones no larger than a hazel-nut may remain in strong or dilute acid for months, and may not be perceptibly acted upon. A bit of bone, when brought in contact with sulphuric acid or oil of vitriol, is immediately attacked by it upon the *surface*, and the action goes on but a little while before a film or coating of *insoluble* gypsum or sulphate of lime forms upon the surface, and this *prevents farther action*. In order to dissolve bony structures and fit them for plant food, *they must first be ground to fine powder, and the finer the better*, as the acid can then cut through the little atoms, and disintegrate them entirely. Coarse pounded bones should never be placed in contact with acid with the idea of dissolving them; they will not dissolve. Strong potash lye will dissolve whole bones, and therefore they may be packed in ashes under certain conditions with good results. If a farmer has a quantity of bones on his premises which cannot conveniently be ground, it is better to burn them to whiteness, and in this condition they can be ground in a common stone mill; and the powder when acted upon by acid forms most excellent true super-phosphate of lime, useful for almost all kinds of crops.

Boston Journal of Chemistry.

BOSTON, MAY 1, 1869.

☞ Any one sending us the names of three new subscribers, with advance pay, will be entitled to receive the *Journal* free for one year. For five new subscribers we will send tne Petite Microscope; for twenty-five we will send, in addition to the microscope, a copy of "Stöckhardt's Chemistry for Students," the best elementary treatise yet published; for one hundred new subscribers we will send a complete set of chemicals, together with test-tubes, alcohol lamp, stirring rods, etc., suitable for performing experiments in Stöckhardt's Chemistry.

☞ Premiums are allowed only upon *new* subscribers, not on renewals of subscription by old subscribers.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price, will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

☞ Correspondents are particularly requested to give their names in full, with their Town and State; and, in case of change of residence requiring a corresponding change in the mailing of their papers, to give not only the new address, but the old one also.

☞ Subscribers who are physicians, dentists, or apothecaries will confer a favor by informing us of their profession, as we wish to know accurately the amount of our medical subscription list.

☞ We are unable to supply complete files of either Volume I. or II. of the *Journal*. Of Volume I. (originally issued bi-monthly), Nos. 1, 2, and 3 (July, August, and September, 1866) are now out of print. Of Volume II. (monthly), Nos. 1, 3, 6, and 12 (July, September, and December, 1867, and June, 1868) are also out of print. Of the remaining numbers we have a few copies left, which we will forward to our friends at the following prices: Volume I., three numbers, twenty-five cents; Volume II., eight numbers, fifty cents. We have on hand a few complete files of Volume III. as published. These we will send as ordered, at the rate of six cents per single copy; six copies for twenty-five cents.

A SOLUTION OF A DIFFICULT PROBLEM.

Spirituous liquors used as beverages have caused and are causing an incalculable amount of evil in the world. It would seemingly have been better for the race if atoms of carbon, hydrogen, and oxygen had been rendered incapable of grouping themselves together in a form to produce alcohol. Alcohol is useful in art processes, and it perhaps serves a good end in medicine; yet we are almost ready to say that it could be annihilated without serious inconvenience. The progress of science would not have been essentially retarded, or any great discovery prevented, if alcohol had never been known. Chloroform and other anæsthetics can be manufactured without it; the druggists' medicinal tinctures and extracts can be made available in other forms; the surgeon and naturalist can preserve their morbid anatomical and other specimens in a mixture of water, glycerine, and carbolic acid, equally as well and at much less cost than by the use of alcohol. Its solvent powers are certainly useful to the chemist, but modern science has pointed out very satisfactory substitutes. It serves as a pleasant stimulant in certain forms of disease, but even here it is so often misapplied it would perhaps be as well for invalids if it were never mentioned by physicians. But alcohol is in the world, and mankind have learned to use it for proper as well as for improper purposes, and the question is, how can it be retained for the former and placed beyond reach for the latter.

How to properly and beneficially regulate its sale is a problem among law-makers not easily solved. All laws hitherto made have proved ineffectual or inadequate to meet desirable ends. In our view they are based upon wrong assumptions, and are too complicated. The general license system has proved a failure; vending liquors through State and town agents is not only a miserable failure, but a public disgrace. It opens up a system of fraud and empiricism hurtful to public morals.

In constructing laws, they should be brief, explicit, and, above all, based upon an intelligent and minute knowledge of the subject legislated upon. All "liquor laws," so called, have assumed that *different forms or modifications* of alcohol were needed for medicinal and art uses. Brandy, rum, gin, whiskey, wines, &c. (or factitious mixtures bearing these names), have been placed in State and town liquor-shops, in one State at least (Mass.), and vended under the protection of law, as if each subserved a separate and distinct purpose, and were in fact important each in itself. What is the chemical nature of these various intoxicating liquids? They are all composed of alcohol diluted more or less with water, and holding minute portions of agreeable but unimportant ethers, or flavoring substances. None of these ethers, oils, or flavors, in any important sense, are medicinal; none of them are of the least service to the chemist, artist, or mechanic. The one ingredient *alcohol* is all that is demanded, or that can prove really useful in medicine or the arts. These peculiar substances only render alcohol attractive and pleasant to the taste. Alcohol in itself, if pure, has no marked flavor, is not palatable; and would find but limited sale, and do comparatively but little mischief if it was allowed a free, unrestricted sale. Mix water with it, add oil of juniper and other foreign agents, and call it *gin*; or distil it from the cereal grains, mixed with water and grain oils, and call it *whiskey*; and thousands will drink it as if it were the nectar of the gods. If it is true that *simple alcohol* is the only liquid that can in any way be regarded as useful, why not make brief, plain laws forbidding under severe penalties all persons to manufacture, sell, or transport any kind of spirituous liquids other than *chemically pure* alcohol, or alcohol containing five per cent of pure water. Allow all respectable apothecaries, under certain restrictions, to sell this alcohol, with other chemical and medicinal substances.

A law of this kind would be clear, explicit, easy to enforce; would meet all the requirements of chemists, druggists, physicians, heads of families, etc., and place intoxicating liquids beyond the reach of those who improperly use them. No State or town liquor agents would be required, no complicated official machinery put in operation. Brandy, whiskey, wines, ale, etc., could not be legally vended, and the sensible and correct principle recognized in law that no kind of spirit but pure alcohol is actually needed for any purpose in medicine or the arts.

Oxygen.—Every method devised by which oxygen or oxygenized air may be cheaply supplied possesses great scientific interest. Prof. Graham, of London, has succeeded in increasing the amount of oxygen in the air, by, as it were, filtering it through fine leaves of India rubber. By this treatment he has succeeded in adding thirty-six, forty, and forty-six per cent of oxygen to the air. When air contains as high as forty-six per cent of oxygen, it will re-ignite a glowing taper. This is a most important discovery, and, if practicable upon a large scale, must be of great service in the arts. Supply us with air containing forty-six per cent oxygen, at trifling cost, and we have in our hands one of the most important agents of good it is possible to conceive of. With it we can add to our gas-lights a high degree of illuminating power, and, by promoting more perfect combustion, save immensely in fuel in heating our buildings.

Bleaching Sponges.—The white, beautiful appearing sponges which are sold in the streets of our cities are bleached in the following manner: The softest, finest specimens are selected, and the sand removed from the cavities by shaking; they are then washed in hot water, and, after squeezing out the water, are placed in a bath of dilute hydrochloric (muriatic) acid, and allowed to remain for half an hour. They are then taken out, and, after washing again in hot water, are placed in a fresh bath of the dilute acid, to which has been added six per cent of dissolved hyposulphite of soda, and allowed to remain twenty-four hours. The sponge is finished by washing in water, and drying.

THE JOURNAL CORRESPONDENCE.

The family of *Journal* readers has become so large, and the correspondence so extensive, it must be apparent to our friends that we cannot reply to but few letters other than those of a strictly business character. The average number received each day exceeds *one hundred*, and very many contain requests for information or advice upon agricultural, chemical, or medical subjects which is for the exclusive benefit of the writers. However much we may desire to oblige our patrons by answering their questions, we cannot, as time and strength will not permit. It affords us much gratification to read the kind words regarding the *Journal* contained in so many business letters, and we hope our friends will not omit them if we do not respond, as they greatly encourage us in our labors.

☞ The voluntary, unsolicited additions to our subscription list have reached nearly *one thousand a month* since January. We are receiving from the Southern States—Georgia, Alabama, Florida, North and South Carolina, etc.—large accessions daily.

Money to renew several subscriptions has been received too late to be credited upon the May number. In the next paper the credit will be given.

"Liquid Gas."—A dozen or more *Journal* readers, residing in different towns and States, write to us, inquiring if we know anything regarding the new and wonderful "liquid gas," which is being extensively sold all through the country by travelling agents. It does seem as if every person of common sense and common intelligence could see through a wicked cheat like this. How can there be a "liquid illuminating gas"? The very name shows that it is nothing but a fraud and deception; and yet we are told that hundreds, nay, thousands, are introducing *dangerous, explosive naphtha* into their dwellings, under the name of "liquid gas." How ingenious are the villains who speculate in cheap inflammable liquids! and how credulous are the victims of their schemes. This "liquid gas" is one of the most dangerous of the light coal *naphthas*, and every family in which it is used is incurring a *fearful risk*. The "gas" can be bought of the manufacturers at 15 cents the gallon, and we are told it is sold for 40 or 50 cents a gallon by the "inventors."

Why are not the men engaged in peddling this liquid, or selling "rights" to use it, arrested? There is law enough; why is it not enforced? We say to heads of families, send the scoundrels to prison; they are conspiring against your lives and those of your little ones. Read the 4th section of the statute just passed by the Legislature of this Commonwealth.

"Sec. 4. Any person who shall sell or keep for sale naphtha, under any assumed name ("*liquid gas*" is an assumed name), shall for each offence, upon conviction thereof, be liable to the same penalties provided and set forth in the first two sections of this act."

The penalty is fine and imprisonment. Readers of the *Journal*, whenever you find a man or woman selling or offering for sale any liquid to be used for illuminating purposes, which is alleged to be better, cheaper, or safer than kerosene oil of legal standard, no matter what may be its *name, color*, or *physical characteristics*, it is *safe* to take legal measures against the individual at once. It is your duty to act promptly, and bring the offenders to punishment. We repeat, what we have several times before stated,—*there is not, nor can there be*, any oil or liquid substance devised, suited to household illumination, which is cheaper, safer, or better than well manufactured kerosene of legal standard!

POISONOUS HAIR DYES.

Editor Boston Journal of Chemistry: —

What do you think of Hall's Hair Restorative? I have had several patients who were troubled with severe neuralgic pains and great nervous irritability, with more or less of colic pains, which I could attribute to nothing else than the profuse application of this restorative to the head. T. TEMPLE, M.D.

NORTH AMHERST, Mass.

REMARKS.—This preparation belongs to the class of hair dyes of which our drug stores are full, made of acetate of lead and lac sulphur, with a little glycerine and much water. They are poisonous, and there is good reason to believe that hundreds are suffering from lead poison introduced into the system by the use of these hair dyes. We have a friend who is suffering from severe attacks of lead colic, brought on by the use of these dyes. There are more than forty preparations of this character, made by different parties, bearing different names, all of which find a ready sale. It is the duty of physicians to inquire carefully into the character of the cosmetics and toilet articles used by their patients.

BOOK NOTICES.

T. S. ARTHUR & SONS, Philadelphia, send to us packages of the magazines published by them:—"*Arthur's Home Magazine*," "*Children's Hour*," and "*Once a Month*." These publications are very neatly printed, and much of the reading matter is entertaining and useful. Mr. Arthur's stories are of a moral character, and are well intended, undoubtedly Without designing our remarks to bear upon these magazines, we feel compelled to enter our protest against a class of publications springing up in almost every city and large town, which are exerting a very pernicious influence upon the youth of both sexes. We allude to the *story* books, and *story* magazines, which are being crowded into families, libraries, Sunday and week-day schools, and into rail cars and steamboats. These *stories* are not of the kind strictly belonging to the domain of "yellow covered literature." They are not to be classed as "blood and thunder stories," but are designed to be "moral," "unobjectionable," and yet they are strongly tinctured with the sensational, improbable, unnatural element. The constant reading of such books is wasting the time of our children, perverting their tastes, keeping them under the strain of unnatural excitement, and poorly fitting them to be healthy, practical, useful men and women. The prevalent fashion of inculcating all moral truths, religious precepts, and scientific facts through the medium of "stories" is pernicious and absurd. There are thousands of story books to be found in Sunday-school and public libraries which ought to be committed to the flames. Legitimate literature, in the shape of books of travel, histories, biographies, scientific treatises, such as used to be read, and upon which most of the intellect and moral force of the world rests, are looked upon as dull and unprofitable, by the rising generation. We speak plainly and emphatically upon this subject, because we feel it is one demanding the most earnest and prompt attention.

A SYSTEM OF CHEMISTRY APPLIED TO DYEING. By James Napier, F.C.S.; a new and thoroughly revised edition, including the Chemistry of the Coal Tar Colors, by A. A. Fesquet. Philadelphia: H. C. Baird. 1869.

Napier's system of chemistry applied to dyeing has, for several years, been regarded as a standard, practical work of great value. One edition in England and another in the United States were published, and disposed of soon after they appeared. The present edition is thoroughly revised, and a full description given of the chemistry of the new aniline dyes so largely employed in the industrial arts. This work will prove useful and interesting, not only to practiced dyers, but to scientific and cultivated readers of all classes. For sale by *Williams & Co.*, 100 Washington street.

ILLUSTRATED LIBRARY OF WONDERS. Published by Charles Scribner & Co., New York. A. Williams & Co., 100 Washington Street, Boston. Price, each vol., $1.50.

This Library embraces a series of books, each treating upon some interesting department of science in a popular way. The first is upon *Thunder and Lightning*; the second, upon *Wonders of Optics*; third, *Wonders of Heat*. The treatises are translated from the French of *W. de Fonvielle*, by *T. L. Phipson* F.C.S. The books afford pleasant and instructive family reading, and are admirably adapted to interest youth, and lead them to acquire a taste for scientific investigation.

PENNSYLVANIA HOSPITAL REPORTS. VOL. II. 1869. Philadelphia: Lindsay and Blakiston.

A valuable volume, recording some of the most important cases treated at the hospital during 1868, and presenting many facts and observations of interest to medical men.

HALF YEARLY COMPENDIUM OF MEDICAL SCIENCES, PART 3, JANUARY, 1869. Philadelphia, S. W. Butler, M.D.

This half yearly review or compendium of medical science reflects great credit upon the industry and intelligence of the editors, Drs. S. W. Butler and D. G. Brinton, of Philadelphia. It presents a synopsis of the American and foreign literature of medicine, surgery, and the collateral sciences, for six months, and is therefore indispensable to physicians who desire to keep themselves informed regarding the progress of medicine. It is eminently an American compilation, and contains much drawn from domestic medical literature. The price per annum is $3.00; single numbers $2.00. Our medical readers desiring the volume will please address Dr. S. W. Butler, 115 South Seventh Street, Philadelphia.

A FOURTEEN WEEKS' COURSE IN CHEMISTRY. By J. DORMAN STEELE, Elmira, N. Y. A. S. Barnes & Co., New York. 1868.

Many of the statements contained in this book are so extraordinary, and the general style is so peculiar, a knowledge of its contents should not be confined to teachers and school children exclusively. The perusal of the work fairly upsets a great many of our long cherished notions regarding chemical facts and theories. Indeed it introduces us to a *new kind* of chemistry. The author disclaims originality in his preface, but we think he is entirely too modest. He certainly has a right to be regarded as one of the most *original* of authors.

Of *carbon* he says, page 68, "None of the acids, *except nitric*, corrode it."

The fact that a person is not so tall at night as in the morning is given as an illustration of the destructive agency of oxygen! Page 27.

He says of warm-blooded, hibernating animals, that they "become *cold-blooded* during the winter." Page 26.

Bleaching powder is "produced in great quantities, *in the process* of making sal soda." Page 243.

He informs us that the human body sometimes takes fire spontaneously. "It happens most generally in the case of intemperate persons. In these instances the fire was not easily subdued, nor communicated to other substances,—the body having even burned to ashes, while the garments were unconsumed." Page 80. There has never been an instance of a person taking fire spontaneously and *burning to ashes*. It is a vulgar superstition, unworthy of notice in a school book.

Fluorine "will not unite with oxygen, and *for this reason* exists in the enamel of the teeth." We suppose that the "reason" for the presence of other elements in the enamel is that they *will* unite with oxygen.

Phosphorus, "at temperatures above 32° emits a feeble light; and *at* 60° *bursts into a flame*." Page 102. Describing the burning of a friction match, he says that four compounds are produced,—phosphoric acid, sulphurous acid, carbonic acid, and water. Then follows this profound remark: "During the burning of the sulphur, the value of the match is *entirely prospective*, as the sulphurous acid is not a supporter of combustion." As none of the compounds formed are supporters of combustion, and as "the value of the match" does not seem to depend upon their being or *not* being such supporters, we fail to see the meaning of the statement. We cannot even guess what the author *meant* to say; and there is nothing in the context that throws any light upon the enigma.

He defines *salts* as "ternary compounds." We supposed there were some salts that were *binary* compounds! "NEUTRALS," he says, "have neither the properties of an acid nor a base. Examples: Na Cl, chloride of sodium; KI, iodide of potassium." Page 14.

Without proceeding farther, let us take a complete paragraph, or sentence, from the book, and examine it. Under the head, "*Singular Truth*," is the following:—

"It is a fact, as poetical as it is characteristic, that when the carbonic acid comes forth from the lungs, it is poisonous, fully charged with the seeds of disease, so that if we should re-breathe it, death would inevitably ensue; yet as it passes out it produces all the tones of the human voice; all songs, and prayers, and social conversation. Thus the gross and deadly is, by a divine simplicity, made refined and spiritual, and caused to minister to our highest happiness and welfare." Page 70.

What a jumble of errors and nonsense is here placed before school children! In the first place, carbonic acid is *not* "poisonous." It destroys life when breathed, by excluding oxygen, not by any specific poisonous action. Second, when "it comes forth from the lungs," in itself it does not differ from any other carbonic acid; it contains no more "seeds of disease" than if it came from ignited charcoal. As it "passes out," the volume is so small that it produces no "tones" in the human voice. Tones are produced by expelling inspired air, as in talking and singing, etc. No human being ever sung a song or uttered a "prayer" by the use of carbonic acid!

The whole paragraph, like a hundred others in the book, is sensational, erroneous, foolish.

The style of the book is very objectionable. For *stopper*, the vulgar word "stopple" is used; for *precipitate*, the term "settle"; and so on.

We are informed that another edition is about to be issued, in which all errors will be corrected. If the labor is faithfully executed, it must stand related to former editions as the boy's new jackknife did to the old one, which had not only new blades, but a new handle. The author of this book may be a competent teacher in some departments of study; but he certainly is not a chemist, and should not have undertaken to prepare a treatise upon chemistry.

Parents have a right to know regarding the character of scientific text-books placed in their children's hands for study in schools; and therefore we have felt it a duty to bring this book under review. It is extensively used in schools in various parts of the country, which is certainly a matter of surprise. We should hesitate to state that it is used in some of the public schools of *this city*, if the information rested upon any less substantial basis than personal knowledge.

We have received from Ex-Governor Front, of New Jersey, the "*Report of the Commissioners to Examine the various Systems of Prison Discipline, and propose a new*

plan," appointed by the Senate and General Assembly of New Jersey, in 1868. The commissioners, in the course of their investigations, were led to visit this city, and express their thanks for attentions received from Dr. S. G. Howe, Edward Morton, Judge Russell, and others. The report discusses the whole question of prison discipline, and closes with recommending a plan which in all essentials corresponds with that adopted in Massachusetts.

TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK, 1868.

This volume contains a large amount of medical information of the highest importance and usefulness. We have carefully examined the various papers presented, and do not find one that is dull or common place in the collection. The publication of volumes like this is well calculated to sustain the high scientific reputation of American physicians, and indicates the rapid progress making in medicine, surgery, and the collateral branches of science. We hope to find room in the *Journal* for some of the papers contained in these transactions.

OUR DOMESTIC EXCHANGES.

A list of our domestic exchanges — medical, agricultural, and scientific — is presented below, and the price and place of publication also stated. These journals and papers are, for the most part, ably conducted, and well worthy the patronage of professional and cultivated gentlemen everywhere. There is a growing demand for scientific publications; and many of our readers will be pleased to know the names, terms, and place of publication of the leading journals of this class in our country.

Medicine and Pharmacy.

CINCHO QUININE.

Cincho quinine results from a series of experiments upon the cinchona barks, undertaken in our laboratory with the view of presenting the medicinal alkaloidal principles in an equally efficient but pleasanter and cheaper form than sulphate of quinine. This desirable end has been accomplished. It is manufactured from a mixture of the finest varieties of the Loxa and Calisaya, or the pale and yellow Peruvian barks, and no substance or ingredient but what exists naturally in these barks enters into its composition. The crystallizable, alkaloidal principles of these barks, upon which their therapeutic influence depends, dissociated from mineral acids, constitute cincho quinine.

It presents the tonic and febrifuge properties of bark in their most pleasant, direct, and natural form, and is adopted to replace sulphate of quinine, and is preferable to that salt from the following considerations: —

1st. It exerts the full therapeutic influence of sulphate of quinine, in the same doses, without oppressing the stomach or creating nausea. It does not produce cerebral distress, as sulphate of quinine is apt to do; and in the large number of cases in which it has been tried it has been found to produce much less constitutional disturbance.

2d. It has the great advantage of being nearly tasteless. The bitter is very slight, and not unpleasant to the most sensitive, delicate woman or child.

3d. It is less costly than sulphate of quinine. Like the sulphate of quinine, the price will fluctuate with the rise and fall of barks, but we shall supply it at all times at less than the lowest market price of that salt.

Cincho quinine we present in the form of snow-white, crystalline flakes, easily reduced to powder by rubbing, and perfectly soluble in weak acidulated water. It is placed in vials holding each one ounce, of the same size and form of those holding sulphate of quinine. No directions for its employment are needed, as it may be used in the same quantities and forms and for the same affections as sulphate of quinine, so fully understood by every physician.

Any physician in the United States, by inclosing four three-cent stamps to our address, will receive by return post a specimen of cincho quinine sufficient for satisfactory trial. J. R. N. & Co.

HOPE FOR THE CONSUMPTIVE.

Neither physicians, invalids, nor friends of consumptive invalids should ever relinquish hope in any case. Nothing is more alarming than pulmonary hemorrhage, nothing considered more fatal; and yet how many cases are on record of perfect recovery from this affection in its worst forms. We have a very near relative now in his seventy-eighth year, who during the past thirty years has had more than a dozen attacks of bleeding at the lungs, and yet, with care, he has managed to live comfortably, and perform a great amount of useful labor. The case of President Day, of Yale College, is remarkable. We find in the *Transactions of the Connecticut State Medical Society* some interesting statements regarding him, written by Professor S. G. Hubbard, of New Haven.

"Jeremiah Day was born in Washington, Connecticut, August 2, 1773, and during the war of Independence was old enough to appreciate the nature of the issue involved in that struggle, and well remembered having seen some of the actors. His infancy and boyhood were marked by indications of feeble vitality, and the prospect of his arriving at the maturity of manhood, never very flattering, sensibly diminished as he approached that period. He entered the freshman class in Yale College, in 1789, but was soon obliged to leave college on account of a pulmonary difficulty, which was, doubtless, the incipient stage of the organic disease of the lungs which subsequently developed itself. These symptoms were so far alleviated that for two years he taught a school in Kent and Winchester, when he found his health so much improved that he returned to college, and was graduated in the class of 1795.

The succeeding six years, a period of great feebleness, were spent partly in teaching at Greenfield for a year, as tutor in William's College for two years, and as tutor in Yale College for three years, during which last period he studied theology, and preached occasionally in vacant churches in the vicinity until 1801, when he was elected professor of mathematics and natural philosophy in the college.

He was prevented, however, from entering upon his professional studies by the occurrence of an alarming pulmonary hemorrhage, which happened after a Sabbath service at West Haven, where he had preached for Rev. Dr. Williston. Other hemorrhages followed, by which he was greatly prostrated, losing large quantities of blood. According to the prevailing practice of that time, he was freely bled from the arm, "the doctors taking," as he remarked to me, "nearly all of the little remaining blood in his body."

In this condition of extreme exhaustion, at the age of twenty-eight, he abandoned temporarily the purpose of entering upon the duties of his professorship, and in September of that year he made a voyage to Bermuda, to try the effect upon his health of a warm climate. While there he was treated with tincture digitalis to the extent of producing its cumulating effects, which were so profoundly sedative that for a time his life was despaired of. Indeed so reduced and attenuated was he on leaving home that none of his friends expected to see him again alive; and the published letters of Prof. Kingsley and others of that period lament him as already lost to science and the world. He returned, however, in the following April, but without having experienced any material benefit; so that he now gave up entirely all idea of fulfilling his collegiate appointment, and, bidding farewell to his associates, he retired to his home among the hills of Washington to die.

The hemorrhages continued, and were followed by venesections, until a Dr. Sheldon, of Litchfield, who enjoyed a wide reputation for curing consumption, chanced to see him, and casually remarked that he needed iron, and he believed he could help him.

Although the patient was evidently in a hopeless decline, he was placed under the care of Dr. Sheldon, who would seem to have been an acute observer, and in his knowledge of pathology and therapeutics far in advance of his time. Under the use of preparations of iron, with bark, and nutritious food, Mr. Day soon began to exhibit signs of returning health and strength; and in 1803, although he seemed to his friends literally like one raised from the dead, he was so far restored to health as to be inaugurated as professor. From this time all symptoms of pulmonary disease disappeared and did not return.

On opening the throax only a moderate quantity, perhaps a pint, of serum was found in both cavities. The lungs were everywhere quite free from tubercular deposits, and in all respects healthy. In the apex of each lung, however, was found a dense, corrugated, circular cicatrix, an inch and a half or more in diameter; also a third circular cicatrix on the left side of the left lung, a few inches below the apex, each involving such a depth of tissue as to indicate that the vomicæ of which they were the remains had been large and of long duration. Both lungs were slightly adherent to the apex.

Here, then, was all that remained to mark the beginning, progress, and cure of a tubercular consumption, occupying twelve years in its period of activity, and with its incipient stage dating back more than three quarters of a century; — a legible record, surpassing, in interest and importance to the human race, those of the slabs of Nineveh or the Runic inscriptions.

The bitterness of epsom salts is removed by boiling a little coffee in the solution.

SMALLPOX AND VACCINATION.

The *New York Medical Gazette* makes the following remarks regarding smallpox and the influence of vaccination: —

"Smallpox of a malignant type is prevalent in Montreal. It has also been prevailing in California since June last, with a steady onward mortality, increasing at the rate of ten per cent daily. Public vaccinators have been at work, but the people are vastly more at fault than the public authorities. Still, it is perhaps not sufficiently insisted upon by physicians that repeated thorough vaccinations will eradicate varioloid as well as smallpox; for varioloid is smallpox merely somewhat modified by imperfect vaccination, and, of course, varioloid patients will convey smallpox to unvaccinated or entirely unprotected persons."

We are compelled to differ from our excellent cotemporary regarding this matter. In our view, repeated vaccinations will not eradicate varioloid, and varioloid does not result from imperfect vaccination. Varioloid may properly be regarded as modified smallpox; and those who have suffered most from kinepox vaccination, who have apparently been most thoroughly brought under its influence, are the ones who will most likely have varioloid if exposed to the contagion of smallpox. It depends upon the peculiarities or idiosyncrasies of individuals. Some persons it is almost or quite impossible to bring under the influence of kinepox virus. Others are but slightly affected by it; such we regard as not likely to contract the modified form of smallpox if exposed.

There are peculiarities of organization, peculiar susceptibilities, in certain individuals, which render them liable to contract malignant diseases. We see this in children. How greatly children, even of the same family, differ in this regard. It is one of the most puzzling problems which comes under the notice of medical men, and a subject upon which we earnestly desire light.

IS CONSUMPTION CONTAGIOUS?

Dr. H. I. Bowditch, of this city, writes as follows, in the *Atlantic Monthly*: —

"It was our fortune to attend a man slowly dying of consumption, who, while hopelessly and helplessly ill, was devotedly cared for by his wife, who, at the time, felt herself, and seemed to be, in perfect health. Years after her husband's death, and when she was bravely battling against the disease, which commenced its insidious attacks immediately subsequent to his death, she related to me the following fact, but only on my definite inquiries as to how intimate her relations had been with him during his illness. It seems that often, in wintry nights, that faithful woman would arise from the side of her husband, who was lying with his dress drenched with the chilling sweat of increasing disease, and would persuade him to take her warm clothing and to lie down in the dry, warm place she had just left, while, simply throwing a blanket over it, she would take the spot that had been previously occupied by him! Upon our expressing a horror at the thought of the danger she had run, and which apparently had told with so much power upon her, she quietly remarked that she knew, at the time, the danger she was incurring. She had no thought of danger to herself, and only of her husband's comfort! 'But,' added she, 'I then got what I never recovered from.' A certain vitality seemed to go out of her; and though her nature contended many years against the encroachments of disease, she finally died, always believing that she had taken consumption from her husband, but with a certain martyr-like joy that such had really been the fact.

"We have now in our mind other and analogous cases; as, for example, of husbands having their first cough when 'inhaling the breath of their sick wives,' while administering to their necessities. We have known daughters and sisters, who, full of apparent health and strength, when consumption had seized a mother or sister, have continued to sleep with the invalid, and to breathe the same closed-up atmosphere at night, and to watch all day, without perhaps a moment of healthful out-door exercise. And we have been distressed to find not a few of such healthy young persons gradually beginning to suffer with indigestion, debility, and finally cough, and all the symptoms of consumption. In some instances, in fact, the attendant has died before the life of the original patient has ended. These facts are very significant; and, although we are well aware that, in some of them, other elements of disease may have had their fatal influences, still, the cases have been full of suggestions as to the necessities of greater precautions than we, in this country, have usually taken in this matter."

TWO INTERESTING PARASITIC DISEASES.

J. H. Salisbury, M.D., Cleveland, Ohio, (*Boston Med. and Surg. Journal*), mentions two interesting parasitic diseases, with their treatment.

1st. *Chloasma produced by the Microsporon furfur* (Robin). — A cigar-maker, aged 30, came to him in January last, covered over the whole trunk, anteriorly and posteriorly, with brownish yellow maculæ or spots of irregular outline, from the size of a pin-head to four and six lines in diameter. The spots were not elevated above what appeared to be the surrounding skin. The epidermis was soft and pultaceous, and appeared spongy when scraped with a scalpel. The colored cuticle peeled off like the epidermis from a boiled apple. The sheets and night-dresses were covered with furfuraceous scales. On microscopical examination, the epidermis was found filled with a fungus (*Microsporon furfur*), both in the spore and filamentous stages of development. The spores were developed in multitudes in the dark spots.

Treatment. — The patient was pale and emaciated, and was disturbed at night with alternate sweating and chilliness. A diet of rare beef and bread was ordered, and he was put on the following treatment: —

℞ Acid, sulphuric, aromat. ℥ iij. — S. Put two teaspoonfuls in half a pint of warm water, and wash the body and limbs all over every other night, and wipe dry afterwards.

℞ Nichols' sol. bisulphite of soda, ℥ iij. — S.

Put 1½ tablespoonfuls in half a pint of warm water, and wash the body and limbs all over every other night, and wipe dry. ℞ Tr. ferri chlorid. ℥ iij. — S. Take twenty drops in a full glass of water two hours after each meal. ℞ Tr. cinchonæ comp. ℥ vj.; potass. bromid. ℥ iv. — S. Take a teaspoonful before each meal.

On the fourth day of treatment, the spots had entirely disappeared. Sickly spores and filaments remained in the epidermis, but farther development seemed to be checked. Treatment was continued. At the end of two weeks, the vegetation disappeared, the skin was smooth and healthy, and the patient had gained several pounds in weight and was feeling perfectly well.

2d. *Parasitic Disease of the Conjunctival Membrane and Epidermis of Cheek.* — A carpenter, aged 23, came to him with a diffuse inflammation, roughness, and œdema of eyelids and the surrounding soft parts. The inflammation and scaly condition extended over nearly the whole cheek, to the wing of the nose, and from this point, up the ridge of this organ, to the forehead, involving the entire eyebrow. At first it was considered a case of erysipelas, but on examination, the epidermis was filled with a fungoid growth, in the spore and filamentous stages of development. This vegetation extended to the conjunctival membrane lining the eyelids. The following was prescribed: ℞ Dilute citrine ointment, ℥ ij.; glycerine, ʒ iij. — M. — S. Apply morning, noon, and night to the inside of eye and over the entire affected parts. ℞ Nichols' sol. bisulphite of soda, ʒ ss.; aquæ, ℥ viij. — M. With an atomizer, the spray of this mixture was thrown into the eye and over the cheek, for five minutes, morning and evening, after washing, and before applying the ointment. ℞ Tr. ferri. chlorid. ℥ iij. — S. Take twenty drops in a full tumbler of water two hours after breakfast and dinner. The use of sweets and all organic acids was forbidden; and a plain, substantial diet ordered. The patient rapidly recovered, and in three weeks there was not a trace of the parasitic growth.

TREATMENT OF SCARLET FEVER.

Dr. Charles T. Thompson publishes in the *Lancet* a mode of treatment in scarlet fever for which he claims many and great advantages. On the very first access of the fever the patient is put into a warm bath, and this is repeated as often as the strength of the patient will allow, or the severity of the attack may require. He says, "The first effect of this treatment is to produce a soothing and refreshing feeling in the patient, to be followed soon by such an eruption on the surface, of so vivid a color and in such amount, as would astonish those who have never witnessed it. Thus one of the greatest dangers of this fearful disease — the suppression of the eruption — is escaped."

After the first or second bath, appetite usually returns, so that the patient's strength may be supported by light and nutritious food. The excreta from the skin are removed as soon as deposited, thus avoiding the dissemination of the disease. Cuticular desquamation is greatly promoted. After the bath the body should be dried by soft linen cloths, with as little friction as possible.

It is added that the irritation of internal organs is at once relieved by this treatment, and the various secretions are deprived of their noxious properties; thus removing additional sources of infection. Another advantage is that a very serious case is soon reduced to a mild one, and the patient recovers in less than half the usual time.

Dr. Thompson states that during fifteen years in which he has pursued this practice he has never lost a patient from scarlet fever; nor can he recall a single instance in which the infection has been carried from the patient to any other person. He also asserts that the terrible sequelæ of this formidable disease are seldom, if ever, met with after the above mode of treatment.

Dr. Alex. Keith, of Normandy, has in the last six months treated six hundred cases of fever, scarlatina, measles, and smallpox, by the internal administration of carbolic acid, with only five deaths. He employs the following formula, "Carbolic acid and acetic acid, of each one drachm to one drachm and a half; tr. opii, one drachm; chloric ether, one drachm; water, eight ounces. Dose, one tablespoonful every four hours. The following he gives as the "physiological effects": — 1st. It produces profuse perspiration. 2d. It rapidly lowers the pulse, so much so that in twenty-four hours the pulse will fall from 120 to 60; skin cool and moist, with subsidence of fever; and in scarlatina, the soreness of the throat much diminished. 4th. After its use for the same time the appetite continues to improve. 5th. I have found it more useful at an early stage of the disease, although given afterwards it very much modifies the symptoms and carries the patient through the different stages of the disease much more quickly than any other treatment I have seen. 6th. In some cases the urine appears smoky, as if fine charcoal had been used with it.

Dr. W. T. Thomas, in the *Transactions of the New York Medical Society*, suggests how smallpox and scarlet fever may spread, in these words: —

"But the poisons of smallpox and scarlet fever will spread in spite of free ventilation, and they retain their power of causing the same disease for a long time, and, in the case of scarlet fever, for months. Then the scabs and epidermic scales are doubtless the active agents of propagation. In the one case, the poison may be a mere cloud of molecules; in the other, it may be contained in the epithelium and pus cells, thrown off from the skin in both cases, and from the throat also in one, which adhere to the walls, clothing, or carpets, becoming partially dry; but then, being dislodged by sweeping, dusting, etc., are blown up into the air and inhaled into the lungs of some one, where they again become active by means of warmth and moisture."

Dr. S. P. Dutcher, of Cleveland, Ohio, recommends in the *Medical and Surgical Reporter* the following prescription to remove dropsical effusions, —

℞ Blue mass.............................gr. v.
Pulv. digitalis,
Pulv. squills,
Pulv. gamboge, } ....aa. gr. x.

M. — Ten pills.
S. — One pill every six hours.

BOSTON JOURNAL OF CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. IV.—No. 1. BOSTON, JULY 1, 1869. [FIFTY CENTS PER ANNUM. SINGLE NUMBERS, SIX CENTS.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston,

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.

RECEIPTS.—A written receipt will be sent by return mail to all subscribers who will enclose a three-cent P. O. stamp, for return postage.

A list of premiums is offered to those who obtain subscribers.

Familiar Science.

REMINISCENCES OF AN EXPERIMENTER.

BY THE EDITOR.

In examining recently the contents of certain dark attics and closets in some of our buildings, the impression was left upon the mind of a friend accompanying us that we had been a rather persistent experimenter in the physical and natural sciences and mechanic arts.

The evidence of this was afforded in the confused heaps of wheels, magnets, coils, batteries, retorts, alembics, beakers, pyrometers, galvanometers, &c., &c., which encumbered the shelves and floors; many of which were curious enough in rudeness of form and construction, and aptly illustrative of the science of a former period.

In these piles of rubbish, the cast-off *debris* of many years of study and toil is written the history of the progress of discovery for more than three decades. Here is an electro-magnet, with lever-attached armature, and an arrangement of wheels,—the remains of rude telegrapic apparatus which we had in operation in 1845, about the time Morse's experiment began to attract attention; here are iron cups, connected with copper and platinum conductors, designed to illustrate the practicability of exploding magazines under water by electricity; here are galvanic batteries of every conceivable form and size, most of which are now cast aside as practically useless; and also disc and cylinders, of glass and rubber and gutta-percha, for experiments in statical electricity; here is a formidable iron cylinder, which resembles a piece of ordnance, designed for the purpose of solidifying, or rather liquefying, carbonic acid gas,—a fashionable experiment twenty years ago. In overturning the dusty contents of the rooms, we discover apparatus illustrative of the discoveries and inventions of each decade. At the commencement of the last, we have the *spectroscope.* This instrument is probably the first one ever constructed and used in this country. It was made for us by the late Mr. Fitz, of New York, in 1860, immediately upon the appearance of Bunsen's and Kirchhoff's papers upon spectrum analysis.

A third of a century devoted to the study of the physical sciences, and their practical, experimental investigation, is an interesting period to look back upon. How greatly extended have been the boundaries of human knowledge, how vast and sublime the results of scientific labor and researches! How many important and useful discoveries and inventions have had their birth and development in that period! We have lived to see a thousand timid, hesitating suggestions in science ripen into demonstrated facts; to see a thousand important truths snatched from the domain of surmise, conjecture, or doubt, and transferred to that of established, unquestioned certainty.

A third of a century ago, when our labors began, we had no lines of telegraph, no ocean steamships, no street rail-cars, no photographic pictures, no aniline colors, no kerosene oil, no steam fire-engines, no painless surgical operations, no gun-cotton, no nitroglycerine, no aluminium, no magnesium, no electroplating, no spectroscope, no positive knowledge of the physical constitution of the stellar worlds, and but five hundred miles of *slow* steam railway in the United States. Our telescopes and microscopes were defective, and comparatively of low power, and we had few of those delicate scientific instruments now so important in every department of research.

The last third of a century has been the most active, the most important period of time that has elapsed since time began. Indeed, more of the great resources of Nature have been developed, more of her intricacies unravelled, a deeper penetration made into her mysteries, than in all the six thousand years since the advent of man upon our earth.

Do we who have lived, and perhaps actively participated, in the accomplishment of these results, realize the stupendous greatness of this epoch of time? It is difficult to do this. We are pleased to talk about it, but our natures do not admit of a full realization of the importance of modern scientific discovery. We are whirled past these great events, as our planet is whirled through the inter-planetary spaces: we know it moves with tremendous velocity, but its motions are wholly unobserved.

The reminiscences of an experimenter and student in science for a period of a third of a century are always of the deepest interest, but they are not always of the most pleasing character. There are recollections of so many instances of the rankest injustice done to ingenious, toiling, self-sacrificing fellow-experimenters, which have sprung from jealousy, selfishness, or hate, the desire is sometimes felt that the powers of memory might be abridged at will. Many of the books in which great discoveries are described and claimed have the wrong names upon the title-page. So powerful is the influence of *prestige* and great names, most of these errors, we fear, will never be corrected.

There are also recollections of disappointments and sad failures in the results of experiments: often some great truth or principle has apparently been within easy grasp, when, lo! unexpected hindrances or errors were discovered, and all our exalted imaginings, and dreams of a name immortal, vanished into thin air, and from a flight most lofty we were compelled to gravitate down to earth again.

In scientific research, there are always more failures than successes. The world learns all about the latter, but only one brain is agitated by the former; and that agitation, Heaven knows, is often deep and prostrating enough to seriously affect a dozen brains.

Experimental labor is exacting, expensive, and in some departments perilous. It is exacting because it demands the whole time and the most intense thought. The hours of the day when other kinds of labor are pros-

ecuted, and which cease with the setting sun, do not suffice for the experimenter. An idea or difficult scientific problem, pressing on the mind, becomes almost a material object there; and if it were a brick, or a lump of lead, it could not more effectually disorder the natural functions of the brain and prevent sleep. A great deal of agitation is made over the hours of labor at the present time, and eight hours of labor and sixteen of rest is clamored for by an influential party. This relates to physical labor. Hard work in this world is not alone the lot of those who handle the hoe and spade, or swing the sledge-hammer. The laborer in the field of experimental research reverses the modern idea, and devotes sixteen hours to work, and eight to imperfect rest.

We should venture to assert in the presence of our neighbors and friends, because they *know* it is true, that we have labored for a third of a century nearly this proportion of our time. We do not expect to have the hours reduced to eight or ten in the twenty-four, at least we shall not this year present a petition to the legislature to that effect.

Experimental research is expensive, as there is a constant drain upon the purse for the implements wherewith to prosecute the labors. Platinum and gold and silver, among the expensive metals, are requisite, and in a thousand little ways money disappears as if by magic. From imperfect memoranda in our possession, it is shown that we have expended during the past third of a century, for apparatus and materials, more than *sixty thousand dollars*. This does not relate, of course, to the large working apparatus in our manufacturing establishment, but solely to that needed in experimental labor. Most of this is now thrown aside as worthless, or retained only as interesting relics of the past.

The experimenter in some departments, as in that of chemical manipulation, is constantly liable to accidents which endanger life and limb. We can look back upon a score of explosions and narrow escapes from vapors and poisonous gases, and the indelible scars remaining show how painful have been some of these casualties. But, upon the whole, the retrospective glances of an experimenter are of the most interesting and pleasant character; and no youth who has the necessary qualifications, the intelligence, the ingenuity, the perseverance, the enthusiasm, should be deterred from entering this field because of the exhausting, exacting, or expensive nature of the labors.

HOW TO TAKE CARE OF THE SICK.

There is not a family into which the *Journal* enters but what is liable at any moment to have some one of its members suddenly stricken down by sickness. How important it is, then, that a thorough knowledge, not only of the general principles of good nursing, but of all the "little things" which contribute to recovery, should be possessed by parents, nurses, and those who have charge of the sick! The attentive, faithful physician can do but little, unless he is aided by the judicious, sensible, intelligent care of those who have his patients in charge, and tens of thousands of lives are lost every year by bad nursing. This article upon the care of the sick is the first one of a series which will appear in the *Journal*, and which will cover the whole grounds of *ventilation, disinfection, cleanliness, light, rest, taking food, kinds of food and drinks*, beds and bedding, &c., &c. The nature of disease and ventilation very naturally form the first topics to be discussed. The directions are mainly such as are given to the nurses in the Philadelphia Hospital for Incurables, prepared by one of the physicians in that institution:

Disease means *want of ease*, and, wherever found, it is a sure sign that something is wrong outside of the body or inside of it. *Discomfort* is one of the earliest signs we have of its approach, and therefore the most valuable. Pain is a later one, more solicitous perhaps, but none the less kind in its intentions for all that. They both come to warn us that something is somewhere wrong, and mean to say that sickness will surely overtake us, unless we see where the wrong is. When found, the mischief which *has* been done should be at once corrected, and its return must be prevented by avoiding in the future that which first *produced* it.

Now there are many little monitors by which these outside conditions favorable to disease are detected. The chief one, or at least the one as much relied upon as any other, is the *smell*. Whenever subtances which have been alive become dead, and are undergoing decay, little particles of them break away from the main mass, float in the air, come in contact with the nostril, and we *smell* them. These vapors, which are bred by decay in decomposing substances, are *poisons*, and, like all other poisons, a little absorbed will contaminate the health of the body, while more will so much affect the health as to produce sickness, and even death.

There is but one conclusion to be drawn from this; and it is, that wherever an unpleasant odor is detected, you may be *certain* that there is something in the air which should not be there, and, if permited to remain, it may sooner or later be attended with evil results. The true means for relief in such a case is, *removal* of the offending cause, whatever it may be. Sometimes this cannot well be done; so we must lessen, as much as lies in our power, its tendency to do evil.

Everybody knows now-a-days that these little broken-off particles or emanations from manure-heaps, refuse from slaughter-houses, drippings from the kitchen, defective privy arrangements, etc., etc., when taken into the body through the air we breathe for a long time enough, will sooner or later bring on "bad health," low fevers, and with other conditions induce fever, cholera, yellow fever, etc. Not only may they *produce* such diseases, but they certainly tend to *transform* into serious diseases what would otherwise be but a trifling affection which should yield to the simplest measures. There is not a physician in extensive practice who does not every day, in his rounds, see *some* disorder withstand his efforts, which he knows should readily yield, and which obstinacy he feels perfectly satisfied is due to the cause referred to, — a poisoned blood.

Besides these causes of disease which can be detected through the smell, and removed by the person himself, or the Health Officer, there is another class of poisons, not so readily detected, but whose presence can be quite as readily demonstrated in other ways. We call them "*poisons*," you see, for they are nothing less than poisons, and physicians, when talking to each other, give them no other name.

They are the "poison vapors" which are bred in the bodies of all living animals.

Most readers know that the bodies of animals are constantly undergoing changes; that is, the old particles, becoming worn out and useless, are thrown into the blood, and carried away, while new ones are taken from the blood and put in their places. These new ones answer the purpose for a while, become old, as did the new ones they supplanted, and in due time yield their places to newer ones, better adapted to the purpose intended. This constant *change* goes on until death, or, more correctly speaking, *life continues so long as those changes take place.* It will be seen that these old decaying particles, as they become useless, must be carried away through the blood and out of the body as soon as possible. The chief means by which this end is accomplished is through the use of pure air, which, as it were, washes away these impure particles from the blood. This air enters pure through the mouth and nostrils into the lungs, and comes out laden with these poisonous materials. If these decaying particles are taken into the lungs again, they not only *prevent* the escape of the poisonous materials from the body, but really add *more* poison to the already laden blood.

Soiled air can no more purify soiled blood than soiled water can cleanse soiled clothes. There is one thing which can do it, and that is, *plenty of pure air*.

Now the question is, how much pure air does it require to answer this purpose? You may have some idea of it, when you remember that an ordinary man spoils not less than a gallon of pure air every minute. This is sixty gallons an hour, or near five hundred in eight hours. In round numbers, about *twenty-five flour barrelfuls of pure air are required in a single night for breathing purposes alone.*

Not only is the air of a room made impure by breathing, but it is made impure by the gas we burn as a light. It is estimated that an ordinary burner consumes as much air as eleven men would do; that is, one gas-burner in three-quarters of an hour consumes as much air as would answer a man for a whole night.

If there is an ordinary stove in the room, it destroys as much air as would twenty-five men. All these things and estimates must be thought of when you hesitate sometimes about putting up or letting down a sash of lights a few inches.

If the house is an old one, there may be a "fireplace" in the room. If so, do not attempt to seal it up, "because the air comes in," as it is just the thing you want, but leave it open, or at least the best part of it. If the house is a more modern one, there is perhaps a "flue"; if so, do not upon any excuse attempt to close it, but let it alone.

A great many persons have an idea that this letting in of pure air, or "VENTILATION," means raising a window a little from the bottom, or opening a door a short distance. They never mind much *where* the window or door opens into; it is all the same so they open somewhere. The idea is not correct. Ventilation means providing a means for the *pure* air to come *in*, and for the *bad* air to get *out*. This can usually be accomplished by drawing down the top sash a few inches, which will let the heated impure air *out* of the room, and by raising up the lower sash a few inches to let the fresh air *into* it. If you wish to know that the hot air really goes out at the upper opening, some time hold a lighted candle near it, when the blaze will be carried outwards by the force of the escaping current; and, if you will hold it to the opening below, the flame will point inwards, from the current of cool air which comes from without. A more certain way to secure the proper amount of fresh air is to have an opening on opposite sides of the room, so that the air will circulate *through* the chamber as much as possible. *Remember not to have the current play over the bed on which the person lies sleeping, as the person might catch a cold.* But, if there is no other way, and some rooms are so constructed that no other means appear possible, it is better to open the windows, and escape the effects of the "draught" by putting an extra covering over the person. Should there not be two windows in the chamber, raise the only one you have, and open the door a little. If no means suggest itself to you by which a desirable amount of pure air can be permanently secured, bear the matter in mind; and some day when your physician comes in, ask him about it. Persons who habitually sleep in such badly ventilated houses are seldom compelled to wait long for an opportunity to ask a physician such things, as it is to the occupants of these houses that he is most frequently summoned.

If pure air, as stated on the preceding page, is so important to people who call themselves in health, how much more important is it to those who are *sick!* Especially is it the case with those who have fevers, etc., which physicians now tell us are conditions of the system overcharged with poisonous materials, poisonous vapors, which, for some reason, have not been thrown out of the blood. Perhaps they were *produced* simply from the want of pure air. The lungs try to throw the load off, as can be detected by the heavy odor the breath has; the skin is trying to do the same thing, as you will see by the sticky, clammy feeling detected there; and a physician will see that a dozen different attempts are made, in one place or in another, with the same object in view. These noxious materials, as they are cast off, tend to poison the air around more and more; so we must assist nature in relieving the patient by keeping a constant supply of fresh air in the chamber where he lies. Not only do we assist in *curing* the patient, by carrying away these poisonous materials by plenty of pure air, but, at the same time, we greatly lessen the

chances of other persons *contracting* the disease by breathing the concentrated poison.

If we add a pint of pure water to a pint of impure water, we *dilute* the impure water, and it is made that much the more pure. If we add a dozen pints of pure water to it, we dilute it still more, and bring it nearer purity yet; but, if we add a certain number more, instead of the impurity becoming *diluted*, it is absolutely *destroyed*, and Dr. Letherby, of London, says that the water is perfectly *pure*. It is the same way with impure air. A certain quantity of pure air, added to it, dilutes the bad air and makes it *less* noxious; while, if a certain quantity more is added, the impurity of the air is destroyed, as is the case with the impure water.

Any person can judge from this of the good effect of much pure air upon bad air.

Most observers have noticed that certain contagious diseases, such as small-pox, scarlet-fever, etc., are very apt to prevail during the winter. The reason of it is a simple one, and is because the poisonous or contagious principle is kept *confined* in the room from the fear of admitting the cold. It becomes so concentrated and virulent that it is capable of producing the disease in others. In warmer weather this prejudice against the fresh air does not exist; the doors and windows are kept open; the fresh air enters in abundance, and *dilutes* the emanations so much that they lose their *power* to extend the disease. These diseases then cease until closed doors come again with the cold weather.

If pure air can do so much in the warm weather, it should be made to do as much for us at all times; and it will do it, if we but give it the opportunity.

This is not only the case in low fevers, scarlet-fever, etc., but the same principle holds true with most other diseases; so the first thing and the last thing a nurse should do is this:

Keep the air the sick person breathes as pure as the air outside, without chilling him. Many persons think, as before remarked, that the thing has been done if a door or window is opened, never mind where the air comes from, whether from a close entry, a foul kitchen, or even from an untidy water-closet. If the air does come from any such place, the sick-room is not "aired," as the saying is, but only *more* poisoned. The kind of air one wants is the best air of the neighborhood, and this usually comes from the outside of the house.

With air, as with water, it should not only be apparently *pure*, but it should also be certainly *fresh*.

With plenty of open windows to let in the pure air, and a little burning fuel to take off the chill, it is an easy matter to get the kind of air all sick persons need. It is a rare thing indeed for a person in bed to "catch cold" while in bed. Indeed, some physicians say they never saw a case of it from such a cause; and, if the bed-clothes are properly tucked in about the shoulders, it is hard to imagine how such a thing could occur.

The time when people are apt to catch cold is just after getting up from the warm bed, when the skin has become somewhat relaxed from many hours or perhaps days of lying there, and rendered less capable of reaction. The same temperature which refreshes a patient in bed, while *protected* by the bed-clothing, might destroy the patient just arisen. Common sense will tell us from this that, while we want pure air, we of course want that which cannot *chill* the sick person.

In most diseased states there is much less heat produced than in health; and there is a constant tendency to a decline and ultimate extinction of the vital powers by the call made upon them to sustain the heat of the body. In such cases, the patient should be looked at with care every little while; and as soon as this *tendency* is discovered, the temperature of the body should be kept up by heat externally applied, as by means of warm bricks, bottles filled with hot water, etc. Such cases of decline of the heat of the body occur at all times, even in summer. This coldness, indicating a decline of vitality, is most apt to happen towards morning, at the time the effect of the preceding day's diet begins to be exhausted. Everybody knows that it is usually towards the morning when we begin to suffer from the effects of cold, and it is because the vital forces are then beginning to slacken from the want of food. If this is the case in health, it is the same in disease. Hence, from midnight until nine or eleven o'clock the next morning, the condition of the patient should always be carefully *watched;* and, as soon as want of heat is noticed, the nurse should at once take means to counteract it.

Although fresh air of the proper temperature is absolutely necessary, the prudent nurse will always arrange its entrance so as *not to allow a current over the patient.* No rule can be laid down here to avoid this, but it must be left much to the judgment of the attendant. If the nurse sees no way to avoid the "draught," be sure to ask the physician, when he comes.

If we are to preserve the air within the room as pure as that without, it is needless to say that the fire must not smoke, and a fire is very apt to smoke if fresh fuel is added in too great a quantity at once. In cities, however, physicians have less frequently to notice a smoke in a room than they have the presence of "gas" from a stove. There are few things more annoying to the sick, especially to those suffering from diseases of the throat, lungs or heart, than the prevalence of this "gas."

In the beginning we spoke of the injurious effects of effluvia or vapors known as "bad smells," and we shall here revert to the subject again in a special manner.

Nothing should *ever* go into the "slop-pail" of a chamber but the refuse water from the wash-basin, etc., and then it should stand no longer than necessary. *Under no circumstances whatever should the contents of any utensil used about the bed ever go into it.*

Arts.

INFLUENCE OF OIL OF SASSAFRAS UPON TOBACCO.

Editor Boston Journal of Chemistry:

The interesting article in the May number of the *Journal* reminds me of experiments made some years ago, when I was a smoker. I think I can suggest to your readers a more agreeable antidote, or denicotizer, than the tannic acid.

A valuable little "Treatise on Fever," by Dr Rezin Thompson, Nashville, Tenn., contains the following statement:

"On one occasion, while waiting upon a tedious case of labor, I amused myself, along with the matrons present, in the enjoyment of the pipe rather freely, and suffered a good deal of vertigo as a consequence. In the course of the conversation which the incident gave rise to, one of the company observed that the dry bark of the sassafras combined with tobacco would prevent its unpleasant effects. On the first opportunity, I made the experiment, and found it true; the sassafras not only preventing the injurious effects of tobacco, but speedily removing them when produced. I tested this repeatedly by smoking in a strong pipe until my head was very disagreeably impressed, and then reloading with a mixture of sassafras bark, a few puffs of which invariably dispelled the unpleasant sensations."

I have again and again, in my own person, verified the statement of Dr. Thompson; but have generally used the oil of sassafras, putting a few drops on the end, and allowing time for its absorption and diffusion through the cigar.

Is there any chemical analogy between oil of sassafras and tannic acid? Or is there any explanation of this identity of effect? Is their action purely chemical and on the nicotine? or is it physiological, and on the nerve-tissue?

Indulge me in some other extracts, which appear to me of great practical value, if true, in reference to the anti-narcotic and other powers of the sassafras:

"I added a drop of the oil of sassafras to every two grains of extract of hyoscyamus. Being very susceptible to the influence of nervous stimulants, I began by taking a common-sized pill, and increased the dose until I took five at once, without producing any other effect than a most delightful sleep, such as I had not enjoyed since, when a child, I used to fall down under the shade of a tree when at play."

He made for a lady a syrup of butternut, containing sixty grains of hyoscyamus and thirty drops of oil sassafras to the half pint. Her little daughter, in the absence of the family, drank a quantity which "contained at least thirty grains. No injurious effects followed."

He gave to a negro suddenly seized with spasm in his presence, during the prevalence of cholera, a quantity of a like mixture, containing "forty grains of hyoscyamus. In a few minutes the spasm relaxed, and the man assisted all day in burying the dead."

"I had tested its power (oil sassafras) fully in destroying the poison of insects and reptiles, such as mosquitos, fleas, spiders, bees, wasps, etc.; and, on one occasion, had an opportunity of testing its powers over the venom of the snake known as the copperhead, and found it succeed promptly."

The little book from which the above extracts are taken was published ten years ago. I have seen no notice of it by the medical journals. He writes like an accurate and truthful observer and narrator of facts, and it seems to me that the statements in reference to the properties of the sassafras are worthy of being known and tested. Let any one susceptible to the disagreeable influence of nicotine put a few drops of the oil on the end of a cigar, or on the tobacco in a pipe, and he will very soon be convinced that it is a complete antidote.

In making the experiment with the pipe, it is best to cover the oiled portion of the tobacco with some that is dry, or it will not burn so readily; or, if a blaze is used to light it, will burn too rapidly, and prove pungent and disagreeable. D. SHELBY, M. D.

HUNTSVILLE, ALABAMA, May 15, 1869.

PLATINIZED LEAD FOR GALVANIC BATTERIES.

Editor Boston Journal of Chemistry:

Some ten or a dozen years ago, having occasion to furnish a number of Smee's batteries for medical use, I found it difficult to procure platinized silver for the negative plates. The idea suggested itself to my mind that, as *lead* is unaffected by sulphuric acid, it might perhaps be substituted for silver in Smee's battery. Knowing the position which lead occupies in the scale of electrical relations, and the comparative feebleness of its conducting power, I confess that my expectations were not very flattering. In order to test the matter under the most favorable circumstances, the purest and cleanest sheet-lead was first roughened by rubbing in two directions with coarse, sharp, clean sand-paper, in order to increase the amount of surface, and also to increase its power to liberate hydrogen. It was then electro-plated with silver, after which a coating of platinum was added.

The plate was then substituted for the silver plate in a Smee battery made by one of the best manufacturers in the United States. I was no less pleased than surprised to observe a considerable increase in the electrical action of the battery. I attributed the improved action mainly to the *roughening* process.

In the next experiment the *silvering* of the lead was omitted, and the platinum deposited directly upon the roughened lead surface. The energy of the electric excitation did not appear to be materially affected by the omission of the silver coating. Since that time I have always substituted platinized lead for platinized silver

in the construction and use of Smee's batteries. It is useless to allude to the gain in point of economy. The difference in the cost of the two metals is not the only advantage.

The glass cell used to hold the acid solution of the ordinary Smee battery may be entirely omitted, and a platinized lead cell used as negative plate in its stead. The platinizing of the lead is an exceedingly simple process. To the physical technologist, electro-platinizing suggests itself, and needs no explanation. Practically, however, all that is necessary is to immerse the plates in, or fill the leaden cell with, a weak solution of platinic chloride. A few hours produces a deposit of sufficient thickness. Parties who may try the substitution of lead for silver plates as described, would confer a favor upon the writer by publishing or communicating the results of their observations. J. B. Hough, M. D.

Ridgeville, Warren Co., O., May 4, 1869.

PROFESSOR HENDRICKS ON FORCE.

Editor Boston Journal of Chemistry :—

On page 136 of the *Journal*, June number, I notice Dr. Hendricks's very ingenious but somewhat speculative article upon "force" as originated and transmitted by molecular motion or vibrations. I will not quarrel with his principal points, but wish to call attention to a single statement, viz : "A stage of condensation of the nebules would ultimately be reached, in which the *radiated* molecular motion would exceed that *absorbed* from the ether, after which the *sum* of the force pertaining to the mass would diminish."

Taking a previous statement of your correspondent, that "all vibratory motion is by the ether," as my basis, I would ask how it is possible for a constant force applied to an inert mass to impart more power than itself possesses, so that it shall react upon itself.

The radiation of force in form of heat from combustion of matter will not react upon the burning matter itself, nor diminish so long as the combustion continues; and, until the source of molecular force is enfeebled, the mass acted upon cannot overcome and return the borrowed force. Water charged to saturation with any soluble salt will not receive more, nor will it exert force upon the denser mineral, thereby weakening itself.

Your correspondent's theory would ultimately deprive the nebular masses of all molecular vibration or force, it having been received from the "luminiferous ether," to which it must return if it diminishes at all, and thus necessitate the admission of a third party to this molecular transaction, which should exert the same power as the spring of a clock upon the pendulum, forever changing the balance of vibration.

As this is not claimed by him, and is of course inadmissible, my theory would be that, when the absorption of force from the superior vibration of the molecules of the ether exactly equalled the radiation from the aggregated matter, that an eternal neutrality would be established, neither force exceeding the other.

I would like to hear your correspondent's explanation of this point.

O. P. Baston.

Newport, N. H.

TELEGRAPHING DURING MAGNETIC STORMS.

Few of our readers understand how seriously magnetic storms affect the telegraphic lines in the country, or how by ingenious expedients the disturbing influence is overcome. Mr. G. B. Prescott, a distinguished electrician, makes the following observations:

"On the evening of the 15th of April a magnetic storm of unusual force prevailed over the entire Northern section of the country, which so seriously affected the operation of the wires that, on some circuits, they could only be worked by taking off the batteries, and employing the auroral current instead. The effect of this great disturbance of the earth's magnetism was manifested with particular power upon the wires between New York and Boston, and for several hours the lines upon this route depended entirely upon this abnormal power for their working current. During the prevalence of this storm, however, I operated upon two wires between the above cities by a plan which rendered them as free from the effects of these earth-currents as a local circuit.

"Every one has observed that the auroral current comes in waves of ever-changing polarity, corresponding in length and direction with the scintillations of the visible aurora. Sometimes these waves continue but a few seconds, and sometimes for a longer time; but their constant change of polarity prevents the successful operation of a wire, because at one moment the auroral wave may augment the strength of current on the line, while at the next it entirely neutralizes it. Therefore it has frequently been found advisable to remove the batteries entirely, and work with the auroral current alone. But the operation of the lines in this manner is very unsatisfactory, owing to the uncertain and fitful character of this force; and therefore any feasible plan by which the wires may be worked under such circumstances is worthy of adoption.

"The plan by which I overcame the difficulties arising from the disturbance of the earth's magnetism was by disconnecting two wires from the earth at Boston, and connecting them together, while I grounded them both at New York, thus forming a loop extending from New York to Boston. As the two wires were both upon the same supports, the auroral wave travelled over each in the same direction, and, by uniting the two wires at one end, the auroral influence upon one wire was made to neutralize that upon the other, and thus the wires were left entirely free.

"Of course it makes no difference how often the polarity of the auroral current changes, or how much the strength of this current may vary, since the direction of the current, and its strength, change as much upon one wire as the other, and therefore the current upon one always exactly equals and neutralizes the other."

NEW PAINT FOR FLOORS.

We learn that a new kind of paint, especially good for floors, is made out of water-glass. It unites not only the qualities of beauty and durability, but is also advantageous as a means of protection against the action of fire. In order to lay on a covering of this paint, first of all the floor is neatly cleaned, then any cracks or crevices between the boards that may exist are luted with a thick dough, made of water-glass and pulverized chalk or gypsum. By means of a stiff brush, a coating of water-glass of the consistency, say, of syrup, is then spread over the floor. Again, in the same manner, a second coating is laid on consisting of water-glass mixed with the desired color. It must, however, be a mineral color, from the fact that the alkalies of the water-glass commonly decompose vegetable colors. This coating having become dry, other layers of water-glass may be thereafter given, until the floor has taken on the required lustrous appearance. In order to give the surface a brightness indicative of polish, it is ground off a little, oiled, and thoroughly dried. In this way a coating for the floor is obtained which is very durable, since the water-glass is not worn away either by means of heat, or yet, on account of its hardness, by means of continued use. As regards beauty and utility, floors coated in this manner are found to be fully equal to the best laquered or varnished ones.

ON NEW EXPLOSIVE POWDERS.

BY M. DESIGNOLLE.

Many improvements having lately been made in the art of war, and particularly in the adoption of breach-loading arms, the want has been felt of new powders to meet the requirements of the present artillery. This want has been supplied by M. Designolle, who has invented a new system of powders, of which carbazotate or picrate of potash is the base. These powders are of four kinds, viz, a musket powder, gunpowder for short-bore cannon, slow gunpowder for cannon with long bores, and an explosive powder for torpedoes and projectiles, destined for the undermining of fortifications. The principal advantages of these new powders are the following : Increase of balistic power, without increase of explosive power, the base remaining the same ; possibility of regulating and varying the effects between the limits of one to ten ; also of regulating at will the rapidity of combustion of this powder, and of increasing the balistic power without changing the mode of manufacture. Other advantages are — regularity in the manner of acquiring the mode of manufacture. Other advantages are — regularity in the manner of action ; suppression of sulphur, and consequently of the vapors of sulphide of potassium and sulphuretted hydrogen ; absence of action on metals; and almost entire suppression of smoke. Into the explosive powders only two components enter,— picrate of potash and nitrate of potash ; the musket and gun powders contain carbon in addition to the above-named ingredients. To prepare these powders, the ingredients are beaten from three to six hours with a proportion of water varying from 6 to 14 per cent, according to the nature of the mixture ; the powder is condensed by means of the hydraulic press, with a pressure of from 30,000 to 100,000 kilos; graining of the powder, and pressing and drying it according to the method employed for the black powder. In order to increase the balistic power, the relative proportion of picrate of potash in the mixture must be increased. For musket powder it has been proved that not more than 20 per cent of picrate of potash is required; while for gunpowders its proportion varies from 8 to 15 per cent. This component (picrate of potash) is of a beautiful golden-yellow color, and crystalizes into prismatic needles possessing a brilliant reflection ; it is insoluble in alcohol, but soluble in about 260 parts of water at 15°, or 14 parts of boiling water. Heated with care, it becomes orange-red at a temperature of 300°, but, on cooling, it assumes its original color. Heated to 310°, it detonates with violence. The researches of M. John Casthellaz on the action of nitric acid on phenic acid improved the method of manufacturing picric acid, and produced chemically pure picrate of potash at such a reasonable price that the new powders are not more expensive than ordinary black powder.

MM. Designolle and Casthellaz give the following proportions for preparing deflagrating mixtures with colored flames :

Golden fire	Picrate of ammonia	50
	Picrate of iron	50
Green fire	Picrate of ammonia	48
	Nitrate of barytes	52
Red fire	Picrate of ammonia	54
	Nitrate of strontian	46

Chemical News.

ON THE USE OF THE CHLORIDE OF GOLD IN MICROSCOPY.

Perhaps no re-agent has of late years played so important a part in microscopy as the chloride of gold. By means of it Conheim first demonstrated the terminations of the nerves in the cornea; and since it has been very generally used, particularly in investigations of the nerves. Its application is very difficult, and it is only after a long series of experiments and failures that proficiency is obtained.

Having had considerable experience with this re-agent in the laboratory of Professor Stricker, in Vienna, and having obtained some very satisfactory results, I hope that a few words on its application may not be out of place. The chloride should be dissolved in distilled water, and the solution should never be stronger than the half of one per cent. The object to be examined should be as fresh as possible, and should remain in the fluid from

three minutes to perhaps an hour, according to its affinity for the re-agent, during which time it assumes a pale straw-color. If the piece be small enough to be readily acted upon, ten or fifteen minutes is almost always sufficient. It is then laid in distilled water, to which just enough acetic acid has been added to give it the faintest possible re-action. In two or three days it will have become purple, verging sometimes on blue, sometimes on red; the latter is the least favorable. The preparation is now enclosed in glycerine, and improves for several days as the color becomes deeper, and as the finest fibres are the last to be affected. If the experiment has succeeded, for it sometimes unaccountably fails, the picture presented is one of the most beautiful and instructive that can be imagined. The nerves, muscular fibres and fibrous tissue appear black on the purple background. Epithelial cells are also colored, but not so well as by nitrate of silver.

Although the color makes fibres visible which are so fine that they can be seen by no other method, it does not determine their character. To prove beyond all doubt that a minute fibre is a nerve, we must be able to follow it to a larger branch. On a very successful preparation of the cornea of a frog, I observed nerve fibres of such minuteness that, with a magnifying power of nearly two thousand diameters, it was impossible to follow them to their terminations. I particularly endeavored to verify the connection, asserted by Kühne, but not generally accepted, between the nerves and the corneal corpuscles. With every advantage, such a connection is very difficult to prove. I often thought I had found one; but, when examined by a higher power, and placed in different lights, it proved to be only apparent, except in a single instance, and then it was not certain that the fibre in question was a nerve. I mention these facts as proofs of the value of the method; for it is no paradox to say that the better the preparation, the more difficult it is to obtain results. As the magnifying power is increased, elements come into view which, by inferior methods, are never seen; and spaces are discovered between bodies supposed to be in connection. The use of the chloride of gold, however, is not yet thoroughly understood, and offers a large field for original investigation.—*T. Dwight, M. D., Boston Medical and Surgical Journal.*

Oil among the Ancients.—The ancients knew no method of refining oil. As a great luxury they mixed it with perfumes, such as essence of roses and sandalwood; but this rather detracted from than added to the burning properties of the liquid, and all that was obtained by the process was an increase of fragrance and a diminution of light. The dwellings of wealthy men like Verres, Mæcenas and Lucullus, who expended extravagant sums upon scented oils, would not have borne comparison, in point of lighting, with the grimiest taproom of a gas-lit public house. The gold and silver lamps, hung by slender, well-wrought chains to marble pilasters, only yielded at their best a lurid tapering flame, that gave out an enormous deal of smoke, fluttered in the slightest breeze, and went out altogether at a gust of wind. Neither was it possible to steady the light by closing the apertures through which the air came; for, had Roman or Grecian houses been possessed of glass windows, they would soon have become uninhabitable. The fresco paintings of Pompeian villas, the delicate colors on the walls of urban palaces, would, in less than a month, have been hopelessly coated with lamp-soot. At the end of an hour's conference of an evening, a party of noble Romans would have resembled a congregation of chimney-sweeps. A tunic dyed in Tyrian purple would have acquired a mourning hue in no time.—*Scientific American.*

Photographers' Baths.—Photographers who use glass-baths will find it a great protection to them if they would place in the bottom of them a layer of pounded glass. If a plate should fall off the dipper, the pounded glass prevents it from striking and breaking the bath. Moreover, the small pieces of film, and other things that sometimes float around in the bath, are caught by the pounded glass, and kept from doing injury to the sensitized plate.—*Philadelphia Photographer.*

Albumenizing Glass.—S. B. Tressler sends to the *Philadelphia Photographer* the following formula for albumenizing glass:

White of 1 egg beaten to a froth,
Rain water 6 to 8 ounces,
Iodide of potassium, 5 to 12 grains,
Liq. ammonia, 2 or 3 drops.
Filter through either cotton or filtering-paper.

I cleanse the glass from dirt and grease by immersing it in a strong solution of nitric acid and water. Wash it well under the tap, then flow with the albumen and rear away to dry. As soon as dry, it is ready for use. Never brush the albumen side. If the dust cannot be blown off, clean the plate over again.

Solvent for old Putty and Paint.—Soft soap mixed with solution of potash or caustic soda, or pearlash and slacked lime mixed with sufficient water to form a paste,—either of these laid on with an old brush or rag, and left for some hours, will render old putty or paint easily removable.

Agriculture.

SOUTHERN AGRICULTURE.

Editor Boston Journal of Chemistry:

As one of the Commissioners of the Louisiana State Board of Emigration, and as a native of the South, I feel called upon to acknowledge the just and generous tribute paid to our people and their beautiful country in the last number of your interesting journal. Allow me to say that sectional animosity here has always yielded to candor and conciliation, and that the Southern heart is as accessible to kindness as are the Southern fields to the universal sunshine in which they are deluged.

An honest and cordial welcome awaits every Northern man and woman who may be attracted by our "green pastures" and "still waters." The truth of every Southerner is pledged to a generous hospitality, and he is prompted by every sentiment of honor to defend his guest and his neighbor.

Political asperities have sometimes disturbed these pleasant relations, but they might have occurred anywhere else, and both parties are generally to blame.

In the name, then, of this State, I invite your people to come and see for themselves. We offer them a salubrious climate, a fertile soil, and a cordial and courteous reception.

Very respectfully, your ob't serv't,
V. O. King, M. D.

New Orleans, La.

Remarks.—We print Dr. King's note, although it was not designed for publication. It will do good, coming as it does from one of the most distinguished and cultivated Southern physicians. Since the article was published in the *Journal* alluded to by Dr. K., several parties have written us, stating that the views presented were incorrect, that Northern people could not live comfortably at the South, owing to persecutions from Southern men and women, etc. *We know better than this.* Such statements only serve to show the utter unfitness of the parties making them to live comfortably *anywhere.* Every community harbors more or less complaining, jealous, and usually conceited individuals, who are not happy unless engaged in efforts to make others as miserable and unhappy as themselves. These persons endeavor to keep up sectional prejudice and hate, which is so detrimental to the interests of the whole country. More than a dozen of our most candid, reliable and intelligent citizens, who have just returned from extended tours through the Southern States, all concur in stating that they were everywhere received with the utmost kindness, and that in no section of the South is there more insecurity to life or property than in any Northern State. It is high time honest, worthy citizens of the North understood this matter.

THE HAYING SEASON.

The season for cutting and curing the grass crop having come round again, we have a few remarks to make and some advice to give, which may be of service to farmer friends. In the first place we advise to begin the work of cutting grass *early.* This we especially recommend, if the hay is to be fed to milch cows during the winter. But few farmers are correctly informed in regard to the great value of early-cut hay as milk-producing food. We made an experiment the past season which proved its high value conclusively. One acre of grass, a mixture of red-top and clover, was cut the nineteenth day of June, cured in two days, taken to the barn, and stored upon a scaffold by itself. On the first of March we put our herd of ten milch cows upon this hay, and almost immediately the increase in the flow of milk amounted to *ten quarts* per day. The hay fed to them up to the first of March was of the same variety, grown upon the same kind of soil, but it was cut in July, from the middle to the last of the month. No more of the early-cut hay was consumed; it spent as well, lasted as long as the later cut. It was fresh, and full of the rich, succulent juices, dry, but perfectly soluble. The money value of the product from this hay, fed to ten cows, was greater by nearly one dollar each day than that from the later cut. If hay is cut early, a good second crop is almost certain to be secured, and this adds greatly in keeping up a good flow of milk during the winter and early spring. The advantages of cutting hay early for milch cows must not be overlooked. In the second place, hay must not be dried too much. We state here what we have often before stated, that, if grass is *entirely* freed from *external moisture,* as that in the form of *dew* and *rain, it will cure better in the mow than anywhere else,* provided enough exposure to wind and sun is had to cause one-half of the water circulating in the vessels of the plant to be evaporated. This is accomplished in six or eight hours of favorable weather. Hay is often spoiled by storing it when it holds considerable moisture arising from dew or rain, but very *seldom* or never when it holds no other than that which is natural to the circulating juices. These are important facts to remember. If grass is cut early in the morning, and thoroughly worked so as to drive off all the dew, it may be safely stored the same day, if it be a favorable one. A pound of over-dried hay is worth only half as much as that which is properly cured. Do not saturate your mows with *salt.* Salt does not *preserve* hay. Its action is unfavorable to curing hay in the mow, as it is a hygrometric substance, or one that attracts moisture. It holds, besides, considerable water of crystallization, and this affords moisture, and helps defeat the end had in view. Wet or damp hay will keep no better by throwing over it salt; and, when this substance is used largely, it is upon the whole injurious to animals who are compelled to eat the hay. Who among men could live upon "salt junk" continually? We must use reason and sound judgment in all our proceedings.

Analysis of Ripe Grapes.—Dr. Classen has done good service to science, as well as technology, by supplying us with these analyses; the grapes, three different kinds, grown in the neighborhood of Kreuznach, were brought promiscuously in the market-place there:—1,000 grammes of fruit yielded—(1) 577, (2) 951, (3) 1032 grammes juice; this consisted in 10,000 parts of solid substance dried at 100° *C.*—(1) 1644, (2) 1897, (3) 2046; grape sugar—1499, 1624, 1740; free acid—72, 68, 40.8; ash—27.83, 30.95, 40.08. The ash contains, as might be expected, a large proportion of potassa and phosphoric acid as the chief constituents, and beside chlorine, sulphuric acid, lime, silica, and small quantities of magnesia, and oxides of iron and manganese.

Boston Journal of Chemistry,

BOSTON, JULY 1, 1869.

☞ Any person sending us the names of *three* new subscribers, with full pay inclosed, will be entitled to a *fourth copy of the* JOURNAL *gratis*. For *five* new subscribers, we will send the *petite microscope*, or one set of Twenty Small Carpenters' Tools in a Hollow Handle — a most convenient article. For *ten*, we will send a copy of Dr. Nichols' book, "*Chemistry of the Farm and the Sea*," or Messrs. Rolfe and Gillet's "*Handbook of the Stars*," or the "*Handbook of Chemistry*," by the same authors. *These are all beautiful and instructive books.* For *twenty* subscribers, we will send the "*American Naturalist*," published by the Peabody Academy of Science, Salem, for one year. This is one of the most interesting and useful publications in the country, devoted to Natural History. Or a Boy's Tool Chest, 13 inches long, 8 inches wide, 8 inches deep, with a complete set of Carpenters' Tools, — Saw, Plane, etc. (The express charges on the Chest to be paid by the receiver.) For *thirty* subscribers, we will send the *Naturalist* and the "*New England Farmer*," an agricultural paper, published in Boston. For one hundred and twenty-five subscribers, a Silver Case American Watch. Price, $30.

☞ Premiums are allowed only upon *new* subscribers, not on renewals of subscription by old subscribers.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States. We will furnish, to those sending for them, specimens of any or all the numbers.

☞ Correspondents are particularly requested to give their names in full, with their Town and State; and, in case of change of residence requiring a corresponding change in the mailing of their papers, to give not only the new address, but the old one also.

☞ Subscribers who are physicians, dentists, or apothecaries will confer a favor by informing us of their profession, as we wish to know accurately the amount of our medical subscription list.

☞ We are unable to supply complete files of either Volume I. or II. of the *Journal*. Of Volume I. (originally issued bi-monthly), Nos. 1, 2, and 3 (July, September and November 1866), are now out of print. Of Volume II. (monthly), Nos. 1, 3, 6, and 12 (July, September, and December, 1867, and June, 1868), are also out of print. Of the remaining numbers we have a few copies left, which we will forward to our friends at the following prices: Volume I., three numbers, twenty-five cents; Volume II., eight numbers, fifty cents; Volume III., one dollar.

STEREOTYPING THE JOURNAL.

We take pleasure in stating that we commence printing Vol. 4 of the *Journal* from *stereotype plates*. After the pages are made up and corrected, they are taken to the foundry and stereotyped, and the plates are used for printing the editions of the paper.

This labor with us, although involving much expense, is unavoidable. We have been greatly troubled to supply back numbers to new subscribers, although at the commencement of each volume many thousand extra copies were printed. With stereotype plates this embarrassment ends, and hereafter any number of copies of this and future issues of the *Journal* can be promptly supplied. The plates are stored in fire-proof vaults, and can at any future period be used in reproducing copies. We have a few full sets of Vol. 3 which we cannot supply at less than *one dollar* unbound. No copies can be furnished *free*. Any one desiring single numbers can procure them, if applied for immediately, by inclosing *ten cents*.

TELESCOPES.

Mr. Tolles of this city, the celebrated optician, has just completed for us a very fine telescope, with a three-inch object-glass. Mr. Tolles has introduced into this instrument some improvements, which are new, and which add very much to its value.

The mechanical appliances for directing it, and easily retaining the object in the field, are admirable, and perfect in construction. It has attached to it a *finder*, with other appliances, also a terrestrial and two celestial eye-pieces. This instrument resolves many double stars, and brings out the moons of Jupiter and the rings of Saturn with great clearness. The moon is brought within about 1,500 miles of the observer, and the ragged openings of its craters and the shadows of its mountains are distinctly defined. The least distance at which objects upon the moon have ever been seen is 42 miles. This would be about the distance of Worcester from Boston, and the view of the moon through Lord Rosse's telescope would afford as distinct conceptions of objects as looking from Bunker Hill Monument at objects in Worcester with the naked eye. In a very clear day, if the elevation was sufficient, it might be that large buildings could be distinguished. Since Locke's celebrated "moon hoax," published thirty years ago, we have had no very minute description of occurrences upon our satellite.

Some of our readers may be curious to inquire why it is, if we can bring objects upon the moon within a range of 42 miles, they cannot be brought within one mile. To overcome the remaining 40 miles, or to bring the moon within one mile of the earth, would require an enormous increase of power in our instruments. It would require at least *ten times* the power of Lord Rosse's great reflector, and in the construction of such telescopes there are at present practical difficulties which seem insurmountable. Beside the difficulties pertaining to instruments, it must be understood that the very augmentation of power defeats the end desired,— clearness of observation. The vibratory motions caused by radiated and reflected solar heat, and the mechanical impurities in our atmosphere, are all hindrances to clear, accurate observation, and the higher the power the more formidable do they become. These obstacles are undoubtedly to be in part removed, but *how*, it is difficult at present to understand.

DEPILATORY POWDERS.—Superfluous hair, as it appears upon various parts of the face and neck, is a great annoyance to ladies, and we are often asked if there is any depilatory which is safe and reliable. Chemistry has not yet suggested a perfectly satisfactory agent for removing this evil. There are, however, several formulas which answer very well for the purpose. The three following are the best:

I.—Take sulphuret of calcium, fresh,
Quicklime, of each equal parts.

Reduce them separately to fine powder; mix, and keep the mixture in a well-stoppered bottle. Safe and effective.

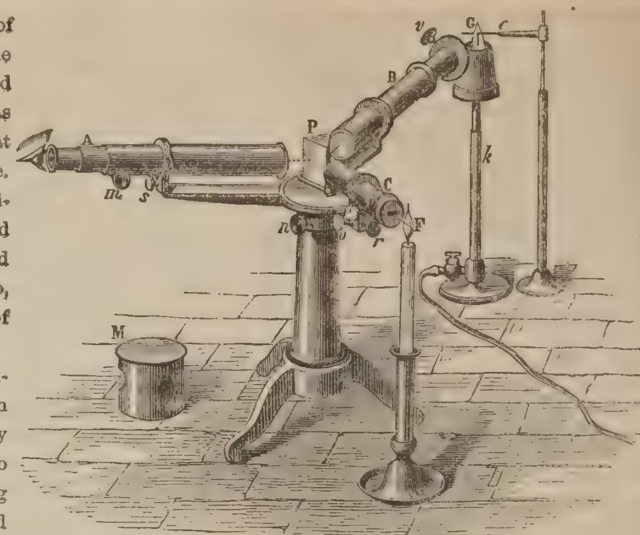
II.—Take hydrosulphuret of sodium, crystallized, 3 parts,
Quicklime, 10 parts,
Starch, 11 parts.

Mix. It should be applied not longer than two minutes. preserve as No. 1.

III.—Take sulphuret of potassium, 1 part,
Pearlash, dry, 1 part,
Quicklime, 8 parts.

Mix. These depilatories, which are in a state of powder, are made into a paste with warm water, and immediately applied to the part, previously shaved close, a little starch being generally added to those which do not contain it, in order to render the paste more manageable.

☞ Those of our subscribers who are in arrears will find bills inclosed in this issue of the *Journal*. It may happen that some bills will be placed in the wrong papers: if this occurs, our friends must excuse us. Those who have *forgotten* us for a year or more, and those who have not paid in *advance* for Vol. 4, will please notice the inclosed *reminder*. *It is only fifty cents.* Inclose it in a letter.



THE SPECTROSCOPE.

We have already devoted several articles to the spectroscope and its wonderful revelations, but the subject is so important and so interesting that many of our readers desire us to recur to it again. We are inclined to gratify this wish, because it is evident that those who have not seen the instrument, and become practically familiar with its operation, have found it difficult to get a clear idea of it from the descriptions usually given. As it is not easy to understand a description without the aid of a figure, we have therefore borrowed from Rolfe and Gillet's *Natural Philosophy* the excellent woodcut given above. With the aid of this illustration, we think that we can make the construction and the use of the apparatus intelligible to most of our readers.

The form of the instrument here represented consists of three small telescopes mounted on a single stand, and directed towards the faces of a prism of flint glass, *P*, by which the *spectrum* to be examined is formed. The telescope *B* is for throwing the light upon *P* in order to *form* the spectrum ; *A* is for *viewing* the spectrum thus formed ; and *C* furnishes the means of *measuring* the parts of the spectrum ; *m*, *s*, *n*, *o*, *i*, and *r* are screws for adjusting the position and focus of the telescopes, and require no detailed explanation.

k is a *Bunsen's lamp*, which is simply a gas-burner, so arranged that it gives a very hot flame with very little light; *c* is a platinum wire, by means of which any substance can be introduced into the flame. Suppose, for instance, that this wire be dipped into a solution of common salt and then put into the flame. The light, before pale and quite colorless, becomes at once of a bright yellow. The lenses of the telescope *B* concentrate this light upon the prism *P*. In passing through the prism, the rays are turned aside from their course, or *refracted*, and at the same time separated so as to form a spectrum upon the object-glass of the telescope *A*. A magnified image of this spectrum is formed within the telescope, and it is this image which is examined by the observer at the other end.

The telescope C, as we have said, merely aids in the measurement of the spectrum. It contains a delicate *micrometer*, or scale of equal parts, very minutely sub divided and marked on glass. This is placed at the end of the telescope nearest the candle *F*. The light of the candle, passing through the micrometer and the lenses of the telescope, forms an image of the micrometer upon the face of the prism *P*. From this the image is reflected into the telescope *A* in such a way that it falls directly over the image of the spectrum, and thus affords the means of measuring with the greatest precision the

relative distances of any dark or bright lines which occur in the spectrum.

The cap *M* is used to cover the prism *P*, to cut off all light except that which comes through the telescopes *B* and *C*. It is removed in the figure, in order that the prism may be seen.

The light from *G* is admitted into the telescope *B* through a very narrow upright slit, the width of which can be adjusted by the screw *v*.

There are various forms of the spectroscope, adapted for various kinds of investigation, but the principle is the same in all.

We have assumed that the reader understands the action of the prism upon the light which passes through it. He knows, of course, that the white light of the sun is not *simple*, but *compound;* a bundle of colored rays some of which are bent more than others (or are more *refrangible*, to use the technical expression,) inside the prism, and thus spread out (or *dispersed*) so as to form the colored band called the *spectrum*. He is aware, too, that not only sunlight, but almost every form of light, is compound, and may be decomposed, forming its characteristic spectrum. It is this last fact which is the foundation of all *spectral analysis*, or the examination of various kinds of light by means of the spectroscope.

So much for the instrument, and the way in which it is used. We wish next to state, as briefly and simply as possible, a few general facts concerning spectra, which ought to be understood before we go on to give an account of the wonderful discoveries that have been made by spectral analysis.

The spectra of all highly-heated bodies may be referred to *three types* or classes:

1st. The spectrum may be *a continuous colored band*, unbroken by either bright or dark lines.

Now, such a spectrum tells us that the body which emits the light is in the *solid* or *liquid* state, but nothing as to its nature. This is a general rule, though in certain cases a gas may give a continuous spectrum. To some of these exceptions we may have occasion to refer in another place.

2d. The spectrum may be made up of *bright lines*. These tell us that the source of the light is *luminous gas;* and, since each gas has its own set of lines, we can tell by an examination of the lines what gas it is which gives a light.

So far, but one exception has been found to this rule. According to Bunsen, solid *erbia* (an oxide of the rare metal *erbium*) gives a spectrum of bright lines.

3d. We may have a spectrum in which a colored band is broken by *dark lines*. These dark lines tell us nothing of the source of the light, but show that *between us and that source* there are *vapors of low temperature* which "by a selective power of absorption" peculiar to them have *quenched* certain of the rays of light, and have not been able to replace them by light of their own. Now, it is a law of light, that *gases absorb the same kind of light as they emit when heated*. The kinds of light absorbed by each vapor, then, producing the *dark* lines just mentioned, will correspond with the set of *bright* lines in the spectrum of the light emitted by the vapor when luminous. A comparison therefore of the *bright* lines in the spectra of *known* substances with the *dark* lines in a spectrum will enable us to tell whether the vapors of low temperature *contain those substances*. Let this fact be understood and remembered, for it is the key to some of the most striking discoveries made by the spectroscope, to which we shall refer in another article.

POPULAR LECTURES ON SCIENCE.

In our April number, under the heading, "A Bishop on Science," we made a few comments upon the newspaper reports of a lecture by Bishop Coxe, of New York. Our criticisms have drawn forth the following letter from the bishop, published in the Buffalo journals, which, in justice to him, we are very happy to reprint: —

BISHOP COXE'S LETTER.

Bishop Coxe presents his compliments to the editor of the Boston *Journal of Chemistry*, and begs to thank him for some very just statements as to the "inaccuracy of reporters," which appeared in the *Journal*, in the course of certain strictures of which he was the subject. So long as such strictures were confined to mere newspapers, quarrelling with their own loose and disproportionate recollections of what was said, the bishop felt himself at liberty to adhere to his ordinary rule of making no reply. When respectable scientific periodicals take up such loose reports and comment on them, although with liberal abatements for their inaccuracy, it may be worth while that truth should be briefly told. The truth is this: *The bishop stated no scientific theories of his own*, but mentioned that of Humboldt as to earthquakes and internal heat, and that of Olbers as to the asteroids. His plan was to show the uncertainties of science and the stability of divine revelation. Consequently, it is with Humboldt and with Olbers that the *Journal* quarrels, and not with the bishop. The contempt with which the *Journal* dismisses the theories of these very learned men merely confirms one point in the bishop's position, which was, that, if their views be true, they do not conflict with the Bible, but confirm it; if false, they illustrate the fact that "*scientific* men are often *very rash and dogmatic* on disputed points," a vice which the *Journal* attributes to "*un*scientific men," as if they were alone in this fault.

BUFFALO, May 7, 1869.

So far as this particular case is concerned, we should be very willing to leave it just as it now stands; but there are one or two points of general interest suggested by the bishop's letter, and upon these we have a few words to say.

In the first place, we believe that popular lecturers who discuss scientific topics, without having prepared themselves for the task by a thorough study of those topics, cannot be acquitted of the charge of *rashness*. They are rash and presumptuous in attempting to do what cannot be done properly without special and elaborate preparation. They get but a partial or one-sided view of the subject, and go before the people with the oracular tone of the teacher; and the mischief of it is that they *are* the popular teachers of science. Thousands of people have had no instruction in science, have not even read popular books on science (many of which, by the way, are open to these very same objections), and they look up to the lecturer as one who "speaks with authority." The newspapers, as we have seen, give their blundering reports of the crude and incomplete statements of the lecturer, and the mischief is thus multiplied and extended.

Bishop Coxe (we refer to his case merely as the one nearest at hand) tells us, for instance, that he stated no scientific theories of his own, but mentioned that of Olbers as to the asteroids; and he did this "to show the uncertainties of science" as contrasted with "the stability of revealed religion." Now, the theory of Olbers was enunciated at a time when but *two* asteroids had been discovered. He found that the orbits of these two planets came very near each other at one point, and this circumstance led him to conjecture that the two were fragments of a larger body shattered by some great convulsion. A third was soon discovered; and Olbers himself, by searching just where, according to his theory, he was most likely to pick up more of the broken pieces, actually found a *fourth*.

This was all that was done in this field of investigation before the death of Olbers (and for nearly forty years afterwards), and it all tended to give great plausibility to his theory. But in 1845 a fifth asteroid was discovered, and the number has now increased to 108. A dozen were discovered in 1868, and several have since been detected. These planets are spread through a zone of more than one hundred and fifty millions of miles in breadth; and it is no longer conceivable that they are the fragments of one original body. As Loomis concisely states it:

"If these bodies ever composed a single planet, which burst into fragments, then, since the orbits all started from a common point, each must return to the same point in every revolution; in other words, all the orbits should have a common point of intersection. Such, however, is far from being the case. The orbits are spread over a large extent, and the smallest known orbit is everywhere distant from the largest by at least fifty millions of miles."

Now, wherein does this illustrate "the uncertainties of science"? All that science can do is to classify *facts already found*, and to deduce from the facts the most plausible theory as to their causes. If fresh discoveries refute the former theories, it must devise new theories which will explain the new facts as well as the old. Olbers explained the existence of his four little planets as well as he could; but, had he lived to see the large increase of the family, we believe that he would have discarded his theory. Very likely he would have adopted the nebular hypothesis of Laplace, which, as we have shown in a former article (Feb., 1869), explains fully *all* the known facts of our planetary system.

In the second place, it does not seem to us that scientific men, and especially those of the very first rank, are apt to be "rash and dogmatic" in the enunciation of their theories. Preachers, lecturers, and newspaper writers are continually making the accusation, but there is really very little ground for it. Indeed, it appears to us to be a marked characteristic of the best modern writers on science that they draw the line very carefully between *fact* and *speculation*, between what we *know* and what we *may believe*, and that they state their *theories* with all becoming modesty. And it is specially to their credit that they are most careful to do this in familiar and popular presentations of scientific subjects. We open at random a book that lies on our table, — Tyndall's "Lectures on Sound," a model work of its class, though the author has often been abused for theological views which never appear in his books, — and on page 324 we read these words:

"I do not ask you to consider these views as established, but only as probable. They present the phenomena in a connected and intelligible form, and, should they be doomed to displacement by a more correct or comprehensive theory, it will assuredly be found that the wonder is not diminished by the substitution of the truth."

We could readily quote many such expressions from the writings of the great leaders of modern scientific research, and they show how the spirit and temper of these men are misrepresented by more than one popular lecturer, who, in his blundering report of what they have done, is guilty of the very "rashness and dogmatism" which he unjustly ascribes to them.

☞ The great Musical Peace Jubilee, which occurred in this city in June, was a splendid success. Electricity was used for the first time to discharge the cannon employed in the choruses.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—Our readers who are members of this association are reminded that the next or eighteenth meeting will be held at Salem, Mass., commencing Wednesday, August 18th, and we most sincerely hope that a large number of the members will be present. It will undoubtedly be a pleasant and profitable meeting, and the good people of the quaint old city of Salem are preparing to give to all a hearty welcome. On the afternoon of Wednesday, the first day of the meeting, the association will be invited to participate in the dedication of the Museum of the Peabody Academy of Science. This is a noble, and in many respects an unique collection of objects of natural history, rare curiosities and coins, and works of art. The collection in itself is worth making a long journey to examine; and the beautiful hall, and tasteful scientific arrangement of specimens, add greatly to the effect.

Salem is fast becoming a point of great scientific interest, and the corps of indefatigable laborers in the several fields of scientific research, who now are connected with the Peabody Academy of Science, are fast making themselves known throughout the world. If more self-denying, industrious, accurate investigators can be found anywhere than Professors Putnam, Morse, Hyatt, Packard, &c., we shall be glad to know of them, and record the results of their labors. Among the distinguished gentlemen expected to be present at the meetings of the association is Mr. George Peabody, the founder of the Academy.

☞ Dr. Wm. H. Helm, of Sing Sing, N. Y., has collected at considerable cost one hundred card photographs, of distinguished foreign physicians, surgeons, chemists, specialists, etc., and is willing to supply copies of the same to any one desiring them, at the low price of $15.50 per set, or $2.00 per dozen. It is a positive *luxury* to possess a set of these carefully selected cards, affording, as they do, perfect and clear likenesses of such men as *Virchow*, *Hoffman*, *Bock*, *Bunsen*, *Helmholtz*, *Liebig*, *Ricord*, *Becquerel*, etc., etc. In looking over the collection, we are almost pained to observe the changes which *fifteen years* have produced upon Liebig, Bunsen, Wurtz and others. Liebig, at Heidelberg in 1855, had but few gray hairs, or deep furrows upon his face, but the photograph before us shows him to be *now* an *old man*. And so we are all growing old. Doubtless many of our readers have been pupils of these distinguished men, and they will be glad of an opportunity to procure these photographs.

We will procure and send one dozen cards to any party who will send us the names of twelve new subscribers to the *Journal*, with full pay inclosed, or we will send the full set (one hundred) for sixty new subscribers.

ONE MORE SUBSCRIBER.—We think there is hardly any good and sufficient reason why each and every one of our present subscribers, cannot add another name to our list at the commencement of Vol. 4. How easy it will be for each one to take a copy into a neighbor's house or workshop, and say: "Here is a little journal that you and your family should read. Every paragraph found in it is useful and instructive; it is good, safe, practical reading, *and it costs only* 50 *cents a year*." But few will refuse; the value is so great, and the cost so insignificant. We do not hesitate to ask all of our subscribers to do us this service, inasmuch as the paper can be made to pay the cost of publication only by securing a very large number of subscribers. How many will respond to this suggestion?

Medicine and Pharmacy.

CINCHO-QUININE.

In response to the requests of many physicians, we present some specific formulæ, for the guidance of prescribers in the use of cincho-quinine. The article in the last number of the *Journal* explains in full its chemical, and therapeutical character, and its obvious advantages over the sulphate of quinine as a tonic and anti-periodic. We have sent specimens to several hundred physicians for trial.

FORMULÆ, AND METHODS OF USING CINCHO-QUININE.—A perfectly clear solution of *cincho-quinine* may be made by taking 10 grains, rubbing it fine in a mortar, and gradually adding 2 fluid ozs. of water, in which is dissolved 30 drops of No. 8 acetic acid, or 6 drops of sulphuric acid. The solution is not disagreeably bitter, and a pleasant elixir may be made from the solution by adding syrup and aromatic flavors.

CINCHO-QUININE PILLS.

℞ Cincho-Quinine (finely powdered), xx gr.
Acid Sulph. Aromat. (Elix. Vit.), xx gtts.
Fiat pil., xx.

Mix, and rub in mortar until it becomes hard enough to form into pills. The mixture is at first quite liquid, but soon it hardens, and pills can be readily formed from the mass. This is the preferable form in which to administer the remedy, as the pills are small and can be readily taken. They need no *sugar coating* to render them palatable.

CINCHO-QUININE ELIXIR.

℞ Cincho-Quinine (finely powdered) grs. xlviii.
Aqua Rosæ (fresh) . . . ℥ viii.
Syrupus Simplex . . . . ℥ iv.
Tincture Cardamon . . . ℥ ii.

Mix. Dose, as tonic, a dessertspoonful three times in the twenty-four hours. The elixir should always be shaken before it is administered.

CINCHO-QUININE POWDERS.

℞ Cincho-Quinine . . . . ℥ i.
Sacch. Alba, (powdered) . . ℥ iv.

Rub together in mortar and divide into powders of any size desired.

When cincho-quinine is required to be given in large doses, as in intermittents, the pill form is preferable, as the pills can be made into those containing five grains, and not be inconveniently large.

There are many other ways in which it may be prescribed, which will suggest themselves to the physician.

CARBOLIC ACID AND SMALL POX.

Editor of Boston Journal of Chemistry:

I hope your agitation of the question of carbolic acid solutions in the *Journal* will result in the adoption of solutions with uniform strength, and a nomenclature that will preclude the possibility of error in filling prescriptions. In the late fearful epidemic of small-pox here, I have tested the disinfectant and prophylactic power of the acid in a way that leaves no doubt in my mind of its superior merit. Indeed, during the latter part of the course of the epidemic I trusted to it exclusively. In thirty-six instances of this exclusive use, the disease spread in but one; and that was in a family of very filthy habits, where cleanliness and proper nursing were unattainable.

Respectfully yours, O. O. BURGESS, M. D.
SAN FRANCISCO, CAL.

THE bitterness of sulphate of magnesia may be removed by boiling a little coffee in a solution of the salt The flavor of a decoction of senna may be masked in the same way.

PRESERVATION OF MEDICINES.

Editor Boston Journal of Chemistry:

The question is often asked of the dispenser of medicines, "How long will it retain its properties?"

Having graduated in 1846 as an M. D., I procured some anti-bilious pills which were a most excellent cathartic. I have retained some of them until the present time, and have given them to friends several times in the last month, and find them just as active as ever. They were made twenty-five years since.

C. A. GREENE, M. D.
CAMBRIDGEPORT, MASS.

THE EFFECTS OF ALCOHOL ON THE SYSTEM.—Dr Letheby states that the effects of alcohol are much modified by the substances with which it is associated in different alcoholic liquids: beers and ale, for example, act on the respiratory function by reason of the saccharine and nitrogenous matters they contain; wine also, as well as cider and perry, have a similar action; and, in proportion to their saccharine and acid constituents, brandy and gin lessen the respiratory changes, and the latter acts on the kidneys by reason of the volatile oil it contains; whiskey is uncertain in its effect upon the lungs; while rum, like beer and ale, is a true restorative, as it sustains and increases the vital powers; and he says that the old-fashioned combination of rum and milk as the most powerful restorative with which he is acquainted.—*Medical Record.*

DR. ALEX. BOGGS, according to the *Richmond and Louisville Medical Journal*, recommends, as a substitute for tincture iodine, carbolic acid, and glycerine, the following mixture,—Tr. iodine, one drachm and a half; glycerine, two ounces; solution of chlorinated lime, six ounces. This solution, which is colorless and not disagreeable, may be used advantageously as an injection in diseases of the vagina and rectum, and for allaying severe itching in vulva pruritus, and also in leucorrhœal affections.

LIME-WATER.—Take a piece of unslaked lime (never mind the *size*, because the water will only take up a certain quantity of it); put it into a perfectly clean bottle, and fill the bottle up with *cold* water; keep the bottle corked, and in a cool, dark place, such as a cellar. In a few minutes it is ready for use, and the clear lime-water can be poured off whenever it is needed. When the water is exhausted, fill the bottle again. This may be done three or four times, after which, some new lime must be used, as in the beginning.

COD-LIVER OIL WITH HYPOPHOSPHITES.

Editor Boston Journal of Chemistry.

I have a female patient twenty-five years of age, unmarried, who has been treated through three lung fevers by me; the third one last winter or autumn, the second about two years ago, and the first about four years ago; since the second one, she has been gradually failing, with very evident symptoms of phthisis, and was so low in January, 1869, that all hopes of her recovery were lost. I could do no more than to put her on the cod-liver oil and hypophosphites of lime and soda, and did so. After taking one and a half pints she began to amend rapidly. Before beginning its use she was unable to move herself in bed, cough bad, raised continually, and cavities were easily diagnosed in the apex of both lungs; now she can walk a mile as quick as any one, and looks strong, has little or no cough and expectoration, gains flesh fast, says she owes her life to the oil. Several other patients of mine, with symptoms of incipient phthisis, are taking it, and are improving rapidly. I find it excellent in convalescence from severe attacks of pneumonia; also in some cases of general failure of the vital powers, for which affection it is hard to find a name.

WM. H. GRANT, M.D.
OSSIPEE, N. H., June 15, 1869.

Danger of giving Strong Doses of Camphor. — A case illustrating the above has recently been brought under the notice of the Société de Médecine et de Pharmacie de Grenoble. An enema consisting of five grammes of camphor dissolved in the yolk of an egg was given to a child three years of age suffering from typhoid fever. Symptoms of poisoning soon manifested themselves, — convulsions, lividity of the countenance, stupor, arrest of the urinary secretions, etc. The employment of coffee sufficed to restore the child. — *N. Y. Medical Record.*

The Relief of Pain in Open Cancer. — The field for experience in cancer at this Middlesex hospital is, as is well known, an unusually large one, and opportunity has therefore been afforded for testing fairly the action of remedies in affording relief in this distressing disease. We learn that the exquisite pain which belongs to open cancer is found to be best relieved by the stramonium ointment, which is employed at this institution. The following is the formula for this in the hospital pharmacopœia: Half a pound of fresh stramonium leaves, and two pounds of lard. Mix the bruised leaves with the lard, and expose to a mild heat until the leaves become friable, then strain through lint. The ointment thus prepared is spread upon lint, and the dressing changed three times a day. — *Lancet.*

ILLUMINATION IN LARYNGOSCOPY.

(Concluded.)

Artificial Light derived from Carboniferous Gases, and from the burning of Animal and Vegetable Oils. — Typical of these, *only* the use of the kerosene light and the ordinary gas light will be described, as they will show the principle of the use of light derived from other sources.

(1) Direct kerosene light, without any special shade used. A good, clean burner, with a clean chimney, is to be mounted on a table or stand, and the observer in auto-laryngoscopy takes such a position that the light will illuminate his throat and not shine in his eyes, and conducts his observations. This is accomplished by holding the mirror of observation in such a manner as that it shades the eyes. Subjective observations may thus be made, but with difficulty.

(2) Direct kerosene light with a special shade: that used by the writer is simply a cylinder of Russia sheet-iron, open at both ends, of sufficient diameter just to encircle the glass shade, Fig. 7. It is made by rolling up a lamina on itself, the longitudinal ends not being soldered, but overlapping each other. It thus can be adjusted to lamp chimneys of different sizes. At the lower part of the cylinder, against the flame of the lamp, is a perforation about one inch in diameter, to which is attached a second cylinder of the same material, open at both ends, of the diameter of the perforation, and two inches in length. This shade covers the light completely, except where it is perforated. The use is obvious. The lamp, protected with this shade, is so placed that its rays shine directly into the mouth. In the case of subjective laryngoscopy, it is either held in the hand of the observer or of an assistant; or it is mounted upon an upright stand, which may be made of an ordinary stair balluster, provided with a sufficiently firm base in the case of a male patient. With a female, unless she stands up for examination, the light must be mounted upon an arm extending at right angles to a stand similar to but heavier than that just mentioned. The use of this shade is very convenient, as it dispenses with all reflectors. The light is strong and steady. It is recommended to those who wish cheaply to practise laryngoscopy by artificial light.

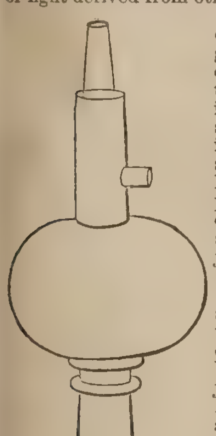


Fig. 7.

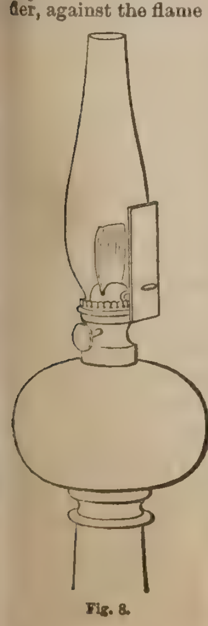

Fig. 8.

It is easy to apply this shade to light, if obtained by burning other oils, only modifying it to accommodate it to the size of the flame, whether it is provided with a shade or not.

Another method of using direct kerosene light is to attach a common visiting card to the lamp so as to exclude the rays from the observer's eyes, Fig. 8. On many lamps there is a spring which stands out at one side, its direction being upwards and outwards. By perforating the card at and near one end downward and inward, when it is shoved on over the spring there is tightness enough to hold it steady and retain it in its place.

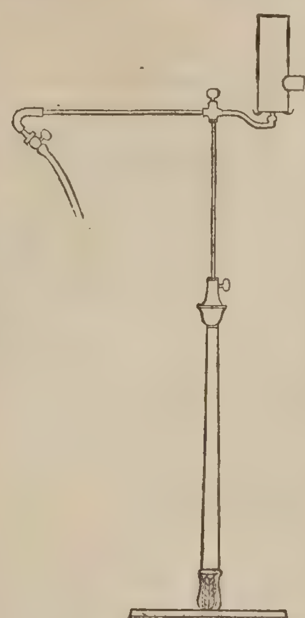

Fig. 9.

(*h*) The Light Obtained from Ordinary Illuminating Gas, used directly. The argand and the carcel burners are the best *forms*, though the others can be used (1) without any special shade. A drop-light or table-light should be employed in the same manner as indicated with the kerosene light, without any special shade; (2) with a special shade, similar to that just described. Here the light is used with the same precautions as have been indicated. It may be held in the hands, placed upon a table, or hung to the fixture overhead.

The best form of *stand* is that employed by photographers for a head-rest; only, in place of the horizontal bar against the forked end of which the head of the sitter leans, a gas pipe eighteen inches long is substituted, one end of which is provided with a burner and the other with an India-rubber tube, to be attached to a feeder. It is capable of adjustment to patients either sitting or standing, male or female. It is firm, easily moved, reliable. A similar horizontal gas-bar arrangement may be attached to a table gas light, but it is limited in its application.

The shade, of Russia iron, is supported by the same wings that hold the glass shade in the argand burner and in the carcel burner. Some of the pickets on the brass holder outside of the glass shade may be turned down for the same purpose.

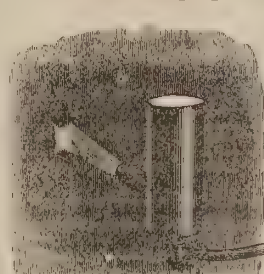

Fig. 10.

Artificial Light Refracted.—In this case the illumination is effected by light thrown into the throat by means of a plane convex lens, of 10 or 14 inches focus, and 1 inch to $2\frac{1}{2}$ inches in diameter. The plane surface is placed next to the light, and the convex towards the mouth to be observed. Such lenses may be adapted to the shade employed in direct artificial light, just described; or they may be applied to a frame-work, as in the case of Dr. Moura Bourillon's pharyngoscope; or they may be adapted to a simple mechanism known as Dr. Morrill Mackenzie's refractor, which is fully described in his late excellent work.

The laryngoscopic lantern of Dr. Oliver, of this city, is of this pattern. It is a very excellent instrument.

Artificial Light Reflected.—This division embraces a large and important portion of the art of laryngoscopy. It is perfectly obvious that, whatever be the superiority in every respect of sunlight, it has the objection that it can be obtained only at certain hours, and then only when the sky is clear. The climate of the United States, in its eastern portion, is generally favorable to clear sunny days, but in other portions of this country, and in most foreign countries, clouds, fogs, mists and haze obscure the heavens so frequently as to render the constant or even occasional use of a ray of sunlight entirely out of the question. Czermak's great credit is that he devised simple reflectors of artificial light which renders laryngoscopy practicable at any time. The principle is that an illuminating ray is thrown into the fauces by reflection upon the laryngscopic mirror, giving reflex visual rays enough for observation. These reflectors, as found in this country, are usually made of glass silvered, about three inches in diameter, and with a focus varying from 10 to 18 inches. Borrowed from Ophthalmoscopy, they are usually perforated in the centre, with a view that the pupil of the eye should observe directly in the axis of the illuminating ray. Here it may be remarked that this method of observation is very well indeed, but it can be entirely dispensed with, leaving the advantage of giving the observer much less to do, and straining his eyes the less.

The reflectors differ more in their mode of mounting than anything else. The simplest method (*a*) known to the writer is that employed by himself. The mirror is attached on a stem $4\frac{1}{2}$ inches long, and $\frac{3}{8}$ inch wide, which has a single hinge joint, capable of movement through one half a circle, yet stiff enough to stay wherever set. A staff about 3 feet long is mounted in a simple block of wood for a base. The upper end is perforated in the long axis for the reception of the stem of the reflector. A stair baluster of mahogany mounted in a turned base of black walnut makes an elegant and cheap stand.

The method of use is very simple. It is placed directly in front of the subject, at about the focal distance, the illumination behind the head of the subject, and the mirror adjusted to throw the light in.

In cases of women whose garments are much in the way, I have used the photographer's head-rest, removing the forked knobbed extremity, and introducing a rod perforated at one end. This is very convenient, as it is capable of adjustment very satisfactorily. The instrument-makers sell an apparatus embodying the same principles, intended to stand upon a table. They must be made heavy enough not to tip over.

Fig. 11.

(*b*) Another method is to mount the reflector upon the forehead of the observer. A strip of metal bent to fit the forehead, perhaps one inch wide, one-eighth thick, and three inches in length is attached to an elastic band large enough to surround the head. The reflector is attached, by means of an universal joint, to the middle of the presenting surface of the metallic strip.

Its application is obvious. In this case the perforation is unnecessary.

(*c*) The reflector placed over the eye. This is accomplished by the means indicated in (*b*), and also preferably by an attachment to a rather heavy frame, such as is used to hold spectacles. The reflector is perforated, and the observation is conducted through the fenestra. This method was suggested by Dr. Semeleder, of Vienna, and once of Mexico; and, under his sanction, has beenvery largely introduced.

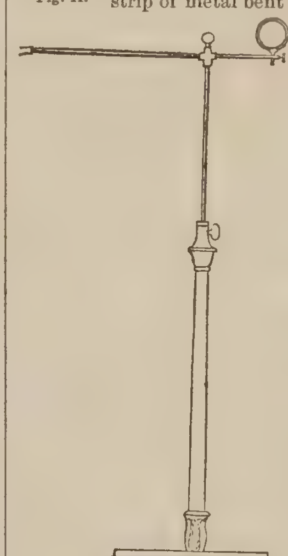

Fig. 12.

(*d*) Another method is the attachment of the reflector to an occipito-frontal band, or a sort of truss iron, extending from the forehead to the occiput, the natural spring of the band holding the instrument in place.

(*e*) Still another mode is to attach the reflector to a shade corresponding to that described under the head of direct artificial light. In this case the mirror is placed at right angles to the axis of the ray of artificial light. Most laryngoscopists employ this method. This combines refraction and reflection. It is the method of Tobold's refractor which is so generally and deservedly used.

(*f*) Yet another way is to place the reflector behind the light; the reflected ray is caught upon the second reflector, and thrown into the mouth. Probably the ingenuity of successive laborers will bring forth other methods of reflection to supersede those already known.

From the perusal of this chapter it is easily seen that direct sunlight, when obtainable, is the light of lights in the exploration of the hidden recesses of the larynx and posterior nares. The great advantages of this light cannot be too strongly impressed upon the reader. It is available to the practitioners in the country, and much simplifies the apparatus. Indeed, with this light, and with the apparatus furnished from a common tinman's shop, laryngoscopy is possible without any special apparatus from outside. A distinguished physician of Boston was called to a patient in the country. Desirous, after his arrival, of viewing the larynx of his patient, and being without his instruments, he acted upon a suggestion previously given him, resorted to a tin-shop with a portion of common broken looking-glass, and in twenty minutes improvised a mirror, with which he made a successful and satisfactory exploration of his patient's larynx.

Magnesium Light.—Owing to its expense and difficult management, it has not been much employed. It gives a lurid, corpse-like aspect which is very unnatural and unpleasant. It is best employed with the direct-light shade.

Oxyhydrogen Light.—This has lately been introduced by an English laryngoscopist. It is questionable whether there is any advantage in such intense illumination: there is a possibility of confusion and dazzling such as is experienced outdoors in a very clear day.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. IV.—No. 2. BOSTON, AUGUST 1, 1869. FITFY CENTS PER ANNUM. SINGLE NUMBERS, SIX CENTS.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.
RECEIPTS.—A written receipt will be sent by return mail to all subscribers who will enclose a three-cent postage stamp, for return postage.
A list of premiums is offered to those who obtain subscribers.

Contents.

Familiar Science.

THE INTERIOR OF THE EARTH.

We all feel a natural curiosity to know what is inside of this round ball we live upon, and to the scientific man the inquiry is one of peculiar interest. Many investigations have been made with a view to settling the question, and many speculations and theories have been the result. The most important of these theories will form the theme of this familiar chat with our readers.

It must be borne in mind from the outset, that the examination of the structure of our globe is necessarily of a very *superficial* character, in the most literal sense of the word. The distance to which we can penetrate the earth is even more insignificant than it seems at first thought. If we represent the earth by an ordinary 12-inch terrestrial globe, the greatest depth to which all natural cavities and artificial borings and minings extend would be shown by a delicate scratch made by the point of a pin on the varnish. If the scratch were more than the *hundredth of an inch* deep, it would be an exaggeration of the reality. We need not wonder, then, that scientific men differ widely in their theories concerning the interior of the big ball whose surface has been scratched so slightly by their most extended explorations.

These theories, setting aside many wild speculations which have no scientific basis to rest upon, are mainly the four following:

First. That the earth consists of a relatively thin crust, filled with molten matter.

Second. That it is nearly or quite solid to the core.

Third. That it has a solid shell and a solid core, with a zone of molten matter between.

Fourth. That it is a solid shell, filled with gaseous matter enormously compressed.

We will take up these theories in turn, stating as briefly and simply as possible the leading arguments which have been urged for and against each of them.

In favor of the first theory—that the earth is a solid shell enclosing a molten mass—we have the following facts:

(1.) The temperature of the earth is found to increase as we go down beneath its surface. This increase varies somewhat in different localities, ranging between one and two degrees Fahrenheit for every one hundred feet. At this rate of increase, the temperature at a depth of forty or fifty miles would be sufficient to melt every known substance.

(2.) Hot springs and artesian wells prove the same increase of heat as we descend into the earth. At Paris, the water from the depth of some 1,800 feet has a temperature of 82°; at Salzworth, in Germany, from a depth of about 2,150 feet, 91°; a hot spring in Arkansas has a temperature of 180°; and many similar instances might be quoted.

(3.) Volcanic phenomena, and especially the pouring forth of streams of lava, which are simply molten rock, are additional proofs of the intense heat which must prevail at great depths.

(4.) The fact that all lavas have essentially the same composition indicates that they probably come from one source, and are not *local* in their origin.

(5.) There are evidences of volcanic action on a most extensive scale in former geological ages.

(6.) The elevation and depression of great areas of the surface of the globe indicate that the crust cannot rest upon an unyielding foundation, but that when one part goes down another goes up. The solid earth is not so solid as it seems, but is slowly heaving up and down in enormous waves. The "everlasting hills" themselves are only the ripples of this world-wide undulation, and even now are rising and falling with the lapse of centuries.

The reasons for the second theory—that the earth is solid to its centre—are purely astronomical.

Experiments made with two pendulums of the same length, one solid and the other a hollow glass ball filled with mercury, show that the latter swings faster. This fact led Prof. Hopkins, of Cambridge (England), to make a series of elaborate mathematical calculations, by which he proved, or *thought* he proved, that certain motions of the earth (known to astronomers as *precession*, *nutation*, etc.) would not be just what they are if the earth were a hollow ball filled with liquid.

It might have been seen, at the outset, that the ball of polished glass filled with the slippery and mobile mercury was not exactly like the earth-ball, with its rough and jagged shell filled with a liquid like molten lava; but this does not appear to have occurred to Hopkins and those who adopted his views. But last summer Delaunay, an eminent astronomer and mathematician, re-examined the problem, showed the fallacy of the premises, and reversed the decision; and also proved *experimentally* that the two spheres—one solid, and the other filled with melted matter—would behave exactly alike.

The astronomical objections to the first theory were thus removed, but these are not the only ones which have been brought forward. In 1849, Thomson asserted, on theoretical grounds, that the melting-point of bodies must rise *under great pressure;* and, in 1854, Hopkins and Bunsen proved this experimentally in the case of certain substances, as spermaceti, wax and sulphur. Hence they inferred that the enormous pressure to which the matter deep down in the earth would be subjected, on account of the weight resting upon it, would render it impossible for it to be melted, even if the temperature were as great as it had been assumed to be.

But further experiments showed that, while the melting-point rises under pressure *up to a certain point*, it then *falls;* so that the matter at great depths, instead of being *less* fusible on account of the superincumbent weight, would be *more* fusible than at the surface. Moreover, experiments on metallic substances gave

wholly different results from those obtained with wax, sulphur, etc.; and, in 1861, Fairbairn proved conclusively, by experiments on much greater pressures than had been tried by Hopkins and Bunsen, that "it is only in the more compressible substances that the law holds true."

If the earth is solid, volcanoes must have a local origin; but, as we have said above, the fact that lava in all parts of the earth is essentially the same compound is against this view. Moreover, recent researches appear to show a *tidal* character in the eruptions of Vesuvius, which would be inconsistent with the theory that their cause is a merely local one.

The third view — that the earth has a solid shell and a solid core, with liquid matter between the two — makes our globe a sort of "gigantic egg." It is a compromise between the first and second theories, and, like most compromises, is not at all satisfactory. It was based on the views of Bunsen and Hopkins, which have been already mentioned; and these, as we have explained, have been completely overthrown by the investigations of Delaunay and others.

The fourth view — that the earth is a shell filled with gases enormously compressed — is based upon purely theoretical grounds. The earth has been *weighed* by several different methods, which it would take too long to explain here, and its mean density is found to be about five and a half times that of water; in other words the earth weighs about five and a half times as much as a globe of water of the same size, or some eight thousand miles in diameter. Now it is argued that, if the interior of the earth were either solid or liquid, and were made up of such substances as we find near the surface, the *condensation by pressure* would inevitably give a greater mean density than five and a half.

But this depends entirely on the assumption that density increases in *direct* ratio to pressure. If this were the case, air, at the depth of eighty miles, would become as dense as water; while water, three hundred and sixty miles down, would have the density of mercury; and clay, which at the surface weighs one hundred and twenty-five pounds the cubic foot, would weigh six *tons* the cubic foot. Hence it is contended that the central mass may consist of gases, which under such enormous pressure could not become more dense than five and a half.

Experiments, however, do not show such unlimited rate of condensation under pressure. It used to be thought that the immense pressure at great depths in the sea would squeeze everything solid, and render all animal life impossible; but deep-sea soundings show that, even at the depth of several miles, there are slimy deposits replete with varied forms of animal life.

Again, there are few gases that can bear a very great pressure without becoming liquid or solid. Under such enormous pressure as this theory assumes to exist deep down in the earth, it is probable that every known gas would be liquefied.

We have given only an outline of the arguments brought to sustain or to demolish these various theories, for our limits permit us to do no more. It will be seen that, on the whole, the balance of argument seems to be in favor of the first and the older theory, that we live on a thin shell, separating us from a heaving sea of liquid fire, of which volcanoes are merely the safety-valves. This theory, moreover, is in harmony with the nebular hypothesis of Laplace, which we have briefly described in a former article (February, 1868), and which is now almost universally accepted as the most simple and satisfactory explanation of the origin and development of our whole solar and stellar system, which can be devised in the present state of our knowledge.

HOW TO TAKE CARE OF THE SICK.

(Continued.)

Before dismissing the subject of ventilating and disinfecting sick-rooms, it is important to remark that the practice of burning rags or sugar, or vaporizing vinegar, to *cover up* unpleasant odors, is a bad practice, and should not be allowed in these days when so many really excellent disinfectants are provided which *destroy*, or chemically change, fetid gases and impure emanations. The smoke, or vaporized particles, of the bodies named, only serve to make filthy odors less perceptible: they exist just the same, and are as potent for evil, as when oppressive and disgusting to the sense of smell. The best purifying agents are chloride of lime, solution of chlorinated soda, sulphate of iron (copperas), and carbolic acid. These are all cheap and easily procured. For purifying sink spouts, cesspools, and vessels used in sick-rooms, any one of these is good, but unquestionably the carbolic acid is the most effective. An aqueous solution holding five per cent of the acid is prepared by the writer, which is very convenient and safe. A spoonful placed in the vessel for receiving the fæcal discharges will completely deodorize and disinfect the contents, and it should always be used in the sick-chamber: vessels of every kind may be cleaned with it, and the clothing carried to the laundry may be sprinkled with the solution. The carbolate of lime, prepared perfectly pure, may be exposed in saucers in sick-rooms with great advantage. In all cases of malignant disease, as diphtheria, scarlet and other fevers, etc., this agent is of the highest consequence. If the odor of carbolic acid is disagreeable to the patient or those in charge, the permanganate of potassa, and the nitrate of lead, supply disinfecting agents entirely odorless and of great power. The attending physician will, however, direct as regards the use of these, and other substances of a like nature.

Dependence should not be placed alone on any chemical purifying agent: there must be *general cleanliness, an abundance* of fresh air and sunshine, in the houses and apartments where the sick are confined.

A house may be filthy where there is not a *pile* of dirt anywhere to be seen. Carpets filled with dust, saturated with grease, etc., uncleansed furniture, old papered walls of years' standing, are just as much sources of impurity to the air as a refuse heap in the cellar. They defile the atmosphere quite as much, and more or less tend to encourage disease. Sweeping with a broom certainly can remove much dirt from a floor, but what it does not sweep out it scatters through the air, making little true improvement. After the dust "settles," the room is usually "dusted," which practically means whipping the dust from one piece of furniture to another with a bunch of feathers. It really seems that the dust had better be left alone, unless it can be *removed* altogether, and the only way to do this is to *wipe* everything with a damp cloth. The floor of a sick-room should really be without a carpet, or, if there is one, it should be well beaten before the patient goes into the room, and again well beaten and aired as soon as the person is done with it.

Few people, never mind who they are, have any idea of the exquisite cleanliness required in the sick-room. The smoky chimney, the dusty furniture, the utensils emptied but once a day, even in the best houses, keep the air of the sick-room constantly dirty. What a person in health "may put up with" for a night only, may really prove a source of suffering, postponement of recovery, or even the hastening of a fatal end, to a sick person who is confined there, perhaps in one posture, for twenty-four hours.

PERSONAL CLEANLINESS IS OF THE HIGHEST IMPORTANCE.

In almost all affections, the function of the skin is more or less disturbed; and, in many important diseases, nature relieves herself almost entirely through the skin. The poisonous materials are merely thrown out by the skin, not carried away from the body by it. Nothing but soap and water can do that. If we permit the sick to remain unwashed, or their clothing to be worn after it has become saturated with perspiration or other excretions, we interfere just as much with the natural process as if a slow poison were given by the mouth; only it is not so rapid perhaps in its operation.

None, but those who have been sick and know from personal experience, can tell how much delicious comfort may be secured after the skin has been carefully washed and properly *dried*. It is not the mere *feeling* of comfort which has been obtained, but it is a sign that the vital powers have been relieved by removing something which was *oppressing* them.

Cleanliness of skin, and ventilation, have much the same end in view,— the removal of noxious materials from the system as rapidly as possible.

The various modes of washing the sick cannot be given here for want of space; besides this, the physician is always ready to give any advice which may be needed. Care should be taken, in all these operations of sponging, washing and cleansing the skin, not to expose too great a surface of the body at once, so as to check the perspiration, which might retard recovery from the disease, or renew the trouble in some other form. In several varieties of diarrhœa, dysentery, etc., when the skin is hard and harsh, the relief to the sick person, from washing with water and using a good deal of soap, is almost beyond calculation. In other cases, sponging with tepid water and soap will be ordered, then tepid water alone, and afterwards properly drying the skin with a soft, warm towel. Sometimes, when water alone is to be used, a little vinegar added to it makes the sponging more refreshing. Of course no one would think of using vinegar at the same time soap is used. Bay rum is very acceptable, also, to the face, neck and hands of sick people, when used after sponging or bathing. If not convenient, some common spirits diluted with water may be substituted.

LIGHT.

A dark house, never mind where it is found, is always an unhealthy one, and usually a dirty one, too. Want of light discourages growth, promotes scrofula, encourages "consumption," and in fact everything else which is bad. It is the unqualified experience of all who have had opportunities of judging, that light is second only in importance to fresh air; and the next worse thing after a close room is a dark one. Many suppose that it is upon the "spirits" only that sunlight acts, and not upon the body. It is just the other way. It does the body good, and the brighter spirits show it. Most persons know that light *purifies* the air; and any one who does not has only to go into a room when the shutters are kept closed, to see what a close and corrupt smell the air has there. It is because the sunlight has not purified the atmosphere.

If possible, the sick-chamber should be the room of the house which has the most sunshine coming into it, and, if the bed can be so placed that the person lying on it can see a good piece of the blue sky, so much the better it will be. If the patient can see out of two windows instead of one, he will be twice as well off. It is found in all hospitals that those rooms facing the sun have fewer deaths, all other things considered, than those which are upon the shady side of the house; and, where statistics have been kept for a period of years, it is found that the average time for recovery is less upon the sunny side than upon the shady side of the building. Not only do fewer patients die, perhaps, in the southernly exposed sides of hospitals, and sick people get well there faster than those on the northern exposure, but it has been shown recently that in asylums, prisons, etc., more of the inmates become ill who are compelled to dwell on the shady side of the building than those who live on the sunny side. Readers know of the sad variety of idiocy (*cretinism*) found on the sides of deep valleys in Switzerland, to which the sun has not free access; while on the other side, more favored by the light, there will, perhaps, be found nothing of the kind.

These facts at once demonstrate the value of sunlight, and it will be a very unwise person, indeed, who neglects to apply his knowledge of its importance to affairs of every-day life.

There are some few diseases — very few, as certain affections of the eye, or of the brain — where a subdued light is required for a time. Even in these, a room on the sunny side of the house, with curtains to the windows, is usually better than one on the shady side.

The first time the reader of this passes through the ward of a hospital, let him observe how almost all the patients lie with their faces turned towards the light. Ask one of them *why* he does so, and he will scarcely be able to give you an answer; but you see he *does* it. The reason is deeper down than his understanding. It is his *nature* to do so, just as it is the nature of plants to always make their way towards the light, and their leaves or flowers to incline towards the sun. While you are looking at the faces turned towards the sunlight, count how many sick you see lying with their faces towards the wall. Among a hundred patients, not more than half a score will be seen avoiding the light.

REST.

It is rarely that the *loudness* of a noise hurts a patient, but it is usually the *kind* of noise that produces an *expectation* upon the mind of something more happening, or being about to happen, — he does not know what it is. The putting up of a scaffold near by perhaps will not trouble him; he knows what that is; while whispering or talking may annoy him beyond endurance. To some, however, any kind of noise is disturbing. A sharp and sudden noise, which is not steady, usually gives more distress than other kinds. Anything which *suddenly* awakens a patient out of his sleep will throw him into greater excitement, and consequently do him more harm, than any continuous sound, however loud it may be.

When a patient sleeps, never under any circumstances let him be awakened, unless you have the sanction of the physician. A sick person who has been asleep but a little while, and is then awakened, very seldom can go to sleep again; while, had he slept a few hours, and then been aroused, he might have fallen asleep again in a few minutes, with but little effort. The reason is something like this: In a sick person, the brain is, as a general thing, weakened and debilitated, like the other parts of the body, and needs strengthening. It gets this by sleep, which is rest. If rest is interrupted a few minutes after it begins, the brain is weakened so much the *more*, and tends the less to sleep. The brain, therefore, not only loses the good of the little sleep it has had, but also its ability to sleep; becoming what physicians call "irritable." If a patient sleeps for a time, the brain becomes that much the stronger, and can the more readily rest the next time.

As before mentioned, no noise which excites a patient's *expectation* should be made in his room. Hence no one should ever speak in low tones near the bed of the patient, or hold a conversation in a room or passage where the sick person can *occasionally* overhear a word. This is absolutely cruel. Such carelessness very frequently induces delirium, especially if the patient is apprehensive about his own condition, and *most sick persons are, no matter how reluctant they may be to admit it.*

While mentioning this matter, there is another thing which occurs to me, and one which is frequently done by a thoughtless nurse. It is when she wishes to make some special inquiry of the physician in regard to the condition of the patient. She usually remains in the room until the physician is ready to leave it, and then calls, with an air of conscious importance, that she has "something particular" to ask him about the patient. The lugubrious countenance assumed by her, to harmonize with her conceptions of importance, sometimes severe enough to make the well feel sick, usually confirms the fears of the sick person to a remarkable degree, indeed, and the nurse returns to a new field of labor in quieting the apprehensions she has cruelly excited. These conversations are usually held just outside of the chamber door, where a word now and then can be overheard by those in the room; and, as intimated, what is overheard, with what is *suspected*, by the poor patient, is frequently the beginning of the worst. Remember always that a cheerful face "doeth good like a medicine."

Unnecessary noises, though slight, disturb a sick person much more than necessary noises of a much greater amount.

A good nurse will see that no door opens with a creak, that no window rattles, and a *very* good one will also see that not even a curtain flaps.

All appearance of *haste* is painful to the sick. The rule is, *do things quickly, and do things quietly.* When you visit the sick, always sit where he can see you without turning his head, and never speak to him from behind, or while he is doing anything. Never divide a sick person's attention by speaking to him while he is in the act of doing anything. Most of the accidents which occur by feeble persons falling, etc., will be found to have happened while the person was attempting to answer some question proposed by a heedless individual.

Never lean against, sit upon, or even shake, the bed in which the sick person lies.

It is the experience of most nurses that, when a person is too sick to read, he is too sick to listen to any one else. If you do read, let it be done slowly, distinctly and steadily. Sick people always prefer having a thing *told* to having it *read* to them.

(*To be continued.*)

"INDUSTRIOUS FLEAS."—A NOVEL EXHIBITION.

Editor Journal of Chemistry:

In your June number is a very interesting article on "The Strength of Man and Insects." Permit me to state a fact that came under my own observation.

In London, Eng., some thirty years ago, was an exhibition of "industrious fleas." I can hardly expect any one who did not witness the marvellous exhibition will credit my statement. Nevertheless, *it is a fact that thousands in America*, doubtless, can certify to as well as myself. Among the wonders exhibited was the following:

A train of Liliputian cars, three, with an engine and tender, made of gold-foil, say one inch high by four long, and three-quarters of an inch wide (one by four and three-quarters), perfect in construction, was propelled by one flea tied to the forward part of the engine. The train moved slowly, but it did move, as could easily be seen by the eye and magnifying glass, say a foot a minute, and the estimated weight of the train was *three thousand* times the weight of the flea dragging it; proving that a flea had the power to propel a body three thousand times its own weight. There were several other fleas attached to the feet of miniature horses and buggies, which ran along the table at different rates of speed, varying in their ages and power. They were exhibited on a circular table, with a circular groove running along the outer edge. When they run into the groove they could not get up the other side, or, if they could, they could not drag up the little vehicles after them.

It may be a matter of interest to say how they were trained. A baby flea was taken immediately after being born, and placed under a watch-glass. Its natural instinct, of course, induced it to jump; in doing this it struck its head with terrific force. After a while it *learned to do anything but jump;* it would walk or run, *but not jump.* After a fortnight's probation, it was *tied* to its work. Some were made to draw teams, some to drive, with little cocked hats tied to them; others again were made into footmen, and stood behind carriages; others, dressed *a la* Napoleon, rode over other fleas, *a la cheval;* others had little steel swords, half an inch long, tied to their wrists, and learned to fence, etc. They were fed at night from the palm of the exhibitor's hand, and put carefully to bed in pill-boxes.

There are doubtless many people in Boston who saw this exhibition, and would willingly corroborate the statements made in this communication.

GEORGE G. W. MORGAN.

SAN FRANCISCO, CAL., June 24, 1869.

THE BLESSINGS OF SUNLIGHT.

There are no blessings which we enjoy here upon this earth — that is, material blessings — but what come to us through the agency of sunlight.

Throughout your whole existence you will find, by following up the same reasoning, that your most trifling act, your most thoughtless movement, has derived its origin from the sun. A blow with the fist, a breath, a sigh, can be exactly estimated in rays of sunshine. Whether you trifle or whether you work, to make such an effort you have been obliged to expend so much strength; and that strength had already been stored in you by the sun, through the agency of a series of transformations. Your clothing is all borrowed from the sun. It is he who has spun every thread of your linen, and fed every fibre of your cloth and flannel. He either bleaches it snowy white, or dyes it purple and scarlet with indigo and madder. He furnishes leather for useful service, and furs and feathers for finery and parade. He gives you your bedding; whether you repose luxuriously between eider-down and wool, or stretch your weary limbs on straw, chaff, Indian corn husks, seaweed, or on even a naked plank, as is the lot of not a few, it is the sun who gives both the one and the other. And what do we receive from regions where the sun, as it were, is not, — from the immediate neighborhood of either pole? We receive just nothing. We cannot even get to them. The absence of the sun bars our progress with an impenetrable zone of ice and snow.

In like manner, your fine cellars of hock, burgundy, and claret are nothing but bottled sunshine from the banks of the Rhine, the slopes of the Cote d'Or, and the pebbly plain of the Medoc. Your butter and cheese are merely solid forms of sunshine absorbed by the pastures of Holland or Cambridgeshire. Your sugar is crystallized sunshine from Jamaica. Your tea, quinine, coffee and spice are embodiments of solar influences shed on the surfaces of China, Peru and the Indian Archipelago. It is the sun's action which sends you to sleep in opium, poisons you in strychnine, and cures in decoctions of tonic herbs. You taste the sun in your sauces, eat him in your meats, and drink him even in your simplest beverage, — water. Without the sun, no blood could flow in your veins; your whole corporeal vitality, your very bodily life, is the result of the overflowings of his bounty.

Nor is this all we owe to our great central luminary. The physical forces with which we are acquainted, — heat, light, electricity, magnetism, chemical affinity, and motion, — dancing their magic round, and alternately assuming each other's form and action, are now believed in all probability to be one in their common birth and origin, — are direct emanations from the sun.

But how grand and beautiful is the theory that *all* material blessings here below come to us entirely and alone from the sun! Its simplicity and unity are completely consistent with the attributes of the Maker. Given motion, and given matter, all the rest follows as an inevitable consequence. All nature, from the simplest fact to the most complex phenomenon, is nothing but a work of destruction or reconstruction, a displacement of force from one point to another, according to laws which are absolutely general.

Arts.

PROFESSOR SANDERS ON GAS PRODUCTION.

We have received a second note from Professor Sanders, in which he expresses the fullest confidence in his ability to furnish a mixture of highly combustible gases (hydrogen and carbonic oxide) at from ten to fifteen cents the 1,000 cubic feet. He says:

"I feel myself again justified in venturing my former assertion, that I can supply a mixture of hydrogen and carbonic oxide gases at a cost of from ten to fifteen cents the 1,000 cubic feet. But this I assert after having only made about 100,000 feet of the gas by this process. Perhaps a more extended experience may modify my assertion, by the addition of five or six cents more to each 1,000 feet of the gas, but certainly not more than this. I have in this city, at No. 276 West Street, a furnace in operation for the production of the steam-gas. As the public will feel an interest in this matter, I think it would not be irrelevant to give a brief description of

the apparatus and its *modus operandi.* I have a furnace made of thin boiler-iron, and lined within with fire-clay tiles. One foot from the bottom of this furnace (which is five feet high) I have the grate. This furnace may be built entirely of common bricks, if necessary, as the best guarantee in the decomposition of the steam, if not very intense. To produce this gas is the simplest of all things. Steam, at seventy or eighty pounds pressure, is allowed to enter below the grate. It passes up through the grate, and, in passing through the furnace (filled with ignited coke), it is, of course, decomposed, being converted into carbonic oxide and hydrogen. I find also that there is likewise a little, light carburetted hydrogen produced. The furnace has a large opening at top, fitted by a slide, to enable the products of the combustion of the coke, as it is being brought up to a red-heat, to pass off into the air. This latter is produced by a fan-blower. This little furnace holds one and a half bushels of coke. If the steam is of a very high pressure (or is very dry), it does not cool down the coke, but this will happen if it be of low pressure, or wet steam. It is really wonderful what a vast volume of gas this little furnace will deliver! My gasometer holds one hundred and twenty-five cubic feet. I can fill it while I hold my breath.

Experiments extended through all last winter to the present time, have demonstrated that this is the cheapest permanent gas that we can get; and that its cost will fill the great desideratum sought, — a cheap gas for heating purposes. I predict, as you have done, that the time will come (and very soon, too) when heating-gas companies will deliver cheap heating-gas to the public, as some gas companies do now their illuminating gas. This will be verified, perhaps before the present year is gone by.

Very respectfully,

J. Milton Sanders.

New York, June 30, 1869.

From the brief description of the method used by Professor Sanders, as presented above, we fear he has fallen into the error which has proved so disastrous to many former inventors and enthusiasts. We do not learn in what respect it differs from the well-known method of decomposing steam as practised in France several years ago, and which was so fully tried in this city in 1863. A gentleman of our acquaintance expended (contrary to our advice) $50,000 in trying experiments like those described in the above note, and yet he failed utterly. There were found to be practical difficulties in the way, which were insurmountable. These difficulties are not all simply mechanical, but relate to the theory of the process, which chemists ought to well understand.

COOKING WITHOUT FIRE.

At the Paris Exhibition in 1867 a curious box was exhibited in the Norwegian department, which cooked food most admirably after the supply of heat was suspended. This box is doubtless one of great utility, and we are surprised that they have not been supplied in this market by some of our enterprising, ingenious artisans. If carefully made, and afforded at reasonable prices, they would meet with a large sale. Any one almost can make the box after the following directions:

Take a box a foot square, line it with successive layers of felt, leaving a round space in the centre large enough to hold the kettle customarily used for cooking food. Have a thick cap to cover up the kettle after it is introduced, so that is in the middle of the box, surrounded by a thick layer of a non-conducting material. When it is required to boil meat, it is only necessary to heat the kettle for a few minutes up to the required temperature, and then to put it into the snug place prepared for it. Here the cooking will go on by itself as long as may be desirable up to certain limits, and the meat will remain warm for five or six hours. By having a series of these boxes, the dinner can be prepared at no expense save the original cost of starting the fire. A little experience will enable the cook to determine the length of time to leave the kettles in the boxes. It is easy to be inferred that the same arrangement will serve to keep ice-cream from melting, or substances from growing warm which have been previously cooled in ice. The value of the felted boxes from a sanitary point of view is to be found in the possibility of providing poor mechanics and laborers with warm food. By portable contrivances it will be easy to keep food warm for some hours, and the advantages to poor workmen cannot be overestimated. To the rich it also insures thoroughly cooked food, while even by them the economy will not be despised.

BISULPHIDE OF CARBON DEODORIZED.

The important uses of bisulphide of carbon in the arts are well known; but its unpleasant odor has been a great drawback to its use in many processes. A process has lately been devised in France for removing this odor. The bisulphide is washed several times with distilled water, and is then transferred to a large retort containing lime. After twenty-four hours' contact with the lime, it is distilled, and received in a flask partly filled with copper turnings (previously roasted to remove all fatty matter, and afterwards reduced by hydrogen), when all odor, except a faint ethereal one, will have been taken away. The lime becomes highly colored.

By the aid of this deodorized bisulphide, Millon and Commaille have succeeded in separating the perfume of milk, and have even detected in it the odor of particular flowers (*Smyrnium olusatrum*, for example) which had been eaten by the cow.

Bleaching Soap. — This is a soda soap prepared according to the excellent prescription of the Prussian pharmacopœia, which prescription has been copied in almost all other works of the kind. The soap is separated by common salt, and after this one-fourth of its weight of sulphite of soda is added, which has been previously made into a homogeneous paste by means of a little water; the soap is next dried in the usual manner. In order to apply this soap, chiefly intended for the bleaching of straw hats, but perfectly fit for application to silk and wool, it is dissolved in its own weight of cold water, and to every two pounds of soap half an ounce of liquid ammonia is added. As soon as the mass has assumed a gelatinous aspect, one part thereof is dissolved in eight parts of warm water. The materials which it is desired to bleach are washed and scrubbed by means of a brush in these soap-suds; while yet moist, the materials are placed in acidulated water (twenty-five parts of water and one and a half hydrochloric acid), left in this liquid for two hours, and then well washed, and rinsed with pure cold water, and dried. This soap is very largely and successfully used in Russia, and was first prepared in that country by Dr. Werner. — *Pharm. Zeitschr, f. Russl.*

Ineradicable Writing. — A French technical paper, specially devoted to the art and science of paper manufacture, states that any alterations or falsifications of writings in ordinary ink may be rendered impossible by passing the paper upon which it is intended to write through a solution of one milligram (0.01543 English grain) of gallic acid in as much pure distilled water as will fill to a moderate depth an ordinary soup-plate. After the paper thus prepared has become thoroughly dry, it may be used as ordinary paper for writing, but any attempt made to alter, falsify, or change anything written thereon, will be left perfectly visible, and may thus be readily detected.

New Marking-Ink for Linen. — M. Kuhr recommends the following preparation: One part of hypophosphite of soda and two parts of gum arabic are dissolved in sixteen parts of distilled water. The tissue, linen or cotton to be marked is thoroughly moistened with liquid, and then left to dry. After having become well dried, the following liquid, composed of one part of nitrate of silver, and six parts of gum dissolved in six parts of distilled water, is used as marking-ink with a quill pen. The mixtures here described are stated to yield an indelible and very deep black-colored ink.

New Mode of Producing Oxygen. — Messrs. Montmagnon and Delaire produce oxygen from the atmosphere by means of charcoal and water, or by saline solutions. They state that 100 litres of fresh charcoal, when exposed to atmospheric air, will absorb 925 litres of oxygen and only 705 litres nitrogen. If the charcoal so saturated with gas is then saturated with water there will be expelled 650 litres of nitrogen and only 350 litres of oxygen. Thus 575 litres of oxygen and only 45 litres of nitrogen are left in the charcoal. These gases they remove by the means of an air pump, when the charcoal is again ready to absorb oxygen and nitrogen from the air.

Agriculture.

BIRDS AND FRUIT.

Editor Journal of Chemistry:

I see by your *Journal* and others that the birds get more than their share of the cherries. Perhaps the little songsters believe the old adage, that "fair exchange is no robbery," music being subject to the laws of traffic as well as fruit. But, if the high price of fruit in the market is chargeable to the voracity of the birds, I would like to have horticulturists try the following experiment for holding them in check, and divide their savings with consumers who have to pay for their cherries in hard-earned scrip.

Issue proposals to the boys to procure the skins of all the stray cats that make night hideous with their music (?), and have them stuffed with some light material, and placed among the branches of cherry-trees, vines, etc. Cheap imitations, made of black cloth, with glass eyes, answer a good purpose.

E. Fairfield.

Portland, June 15.

A Curious Melon. — The wonders pertaining to organized structures are not confined to animals, but there are many plants whose form, instincts and capabilities are most curious and interesting. In a tract of country in the southwestern part of Africa, distinguished for its dry but rich soil, a gigantic perennial melon has been discovered, which is a most delicious, wholesome fruit, and which is largely consumed by the native inhabitants as food. In order that this melon may flourish, it is necessary that it should strike its roots down through the sand *thirty* feet to reach permanent moisture. This it does, and grows in great luxuriance where all else is shrivelled and parched by heat. But this is not all. If it were simply a huge melon, with smooth and delicate skin, every one would be destroyed by wild beasts before half matured. To prevent this, nature has armed its outer rind with a covering of long, sharp, terrible thorns, which so lacerate the mouths and noses of animals that they are glad to leave them alone in all their tempting freshness. Man, with his hands and sharp knives, finds little difficulty in opening the luscious fruit. The natives have no necessity for putting fences about their melon patches, for the plants are self-protective.

Black Knot in Plum-Trees. — It is generally supposed that the black, ugly excrescences found on the limbs of the plum and cherry, and which are now beginning to appear upon some other kinds of fruit-trees, are caused by an insect which perforates the bark, deposits ova, and thus produces a diseased condition called the black knot. Dr. Michener, of Chester, Pa., writes to the *Philadelphia Medical and Surgical Reporter* that this notion is not correct; that the black knot is a parasitic cryptogamous plant belonging to the class fungi, and that it is propagated by *spores* in the same way that all fungoid growths are produced. We believe this statement to be true. The idea that they are produced by insects has arisen from the fact that flies often penetrate into the old, decayed knots, and the larvæ are found there. Destroying the ova or flies does not destroy the black knot; they have nothing whatever to do in originating or maintaining the trouble. The spores of this peculiar fungus float in the air, lodge on the limbs, vegetate, and in this way the annoying parasite soon destroys vast numbers of fruit-trees. No application of whale-oil soap, petroleum, or any other substance, will arrest the growth. By cutting off the excrescences with a sharp knife, a few years of life may be afforded to some trees, but it hardly repays for the trouble. In the war against fungi, no matter what class or order we combat, human skill and science are powerless. If it comes in the form of *rust* upon our wheat, or *smut* upon our corn, or *black knot* upon our plum-trees, we can only look on and see the ruin progress; we can do nothing to avert it.

Value of the Journal to Farmers.—We do not often copy the many pleasant remarks made concerning us by the agricultural press, but the following from *The People*, a large and ably conducted journal published at Concord, N. H., is so hearty and generous in its praise, we are constrained to print it:

"The *Boston Journal of Chemistry*, edited by Dr. Jas. R. Nichols, is published monthly at Boston, at the low price of fifty cents a year. The fourth volume commences with the next number. We have not seen a single number of it but what contained in its agricultural department reliable information of many more times value to any farmer than its cost for the whole year. It treats upon the very subjects upon which farmers need information most. Fifty cents might be expended to better advantage than by subscribing for the *Journal*, but we don't know how."

Tomatoes. —Hull states that his mode of managing tomatoes was to run a knife uncer the plants when they are two or three inches high, so as to cut off the tap-root. This he regards as equal to one transplanting. Some days afterwards he removed the plants, and in a few days more he root-pruned them. They are again transplanted and again root-pruned, —the object being to bring the roots into a compact mass, so as to receive but little check when finally set out. This object is assisted by lifting up with a trowel, and allowing them to fall back. The sash is removed two or three weeks previously, to harden them. During this time, the tops are kept pinched back to about ten inches. When set in the field, they are always tied to stakes, —which saves half the labor of cultivation, keeps the fruit clean, prevents injury to the vines, and facilitates gathering. —*Country Gentleman.*

Lima Beans.—A correspondent of the *Rural New-Yorker* recommends the following method of raising Lima beans: "Take an ordinary nail-keg, as near water-tight as possible, bore quarter-inch holes in every third stave an inch from the bottom. Spade and pulverize thoroughly a circle of ground three feet in diameter. Place the keg in the centre, filled nearly full of good stable-manure, well pounded in; plant the beans end downwards, two inches deep, eight inches apart, and as many inches from the keg, all around it; pour on a pail of water, or as much as the manure will absorb, which may be repeated once a week in dry weather. Place five or six poles a foot from the keg, letting the tops meet over it, and the work is done. Four hills will be found to raise enough for any family. I have adopted the keg and pole cucumbers, and find it works splendidly, as you can pick them without disturbing the vines."

A Novel Method of Catching Mice. —Having on several occasions noticed mice in our seed barrels, I bethought me of some method of how I might trap the little intruders; they having gained entrance by eating through the chime. To kill them with a stick was impracticable, as the little fellows would invariably escape as soon as the lid was raised to any height. I then thought of saturating a piece of cotton with chloroform and throwing it in and then closing the lid. On raising it again in a few minutes, I would find that life had almost or quite departed. Having on one occasion left the piece of cotton in the barrel, on again returning, found three little mice with their heads in close contact with it, and dead. In the evening I saturated another piece and placed it in the barrel, and, on opening it the next morning, to my surprise I found *nine dead mice.*—*Journal of Pharmacy.*

Coal Tar on Shingles.—The *American Agriculturalist* states that coal tar paint causes shingles to decay when applied to roofs. We doubt the correctness of this statement. It seems quite reasonable to suppose that this paint would render shingles in a measure impervious to moisture, and thus prevent decay. We have felt no hesitation in applying it to the roofs of some of our buildings recently.

Boston Journal of Chemistry.

BOSTON, AUGUST 1, 1869.

☞ Any person sending us the names of *three* new subscribers, with full pay enclosed, will be entitled to a *fourth copy of the* JOURNAL *gratis*. For *five* new subscribers, we will send the *petite microscope*. For *eight*. We will send one set of Twenty Small Carpenters' Tools in a Hollow Handle—a most convenient article. For *ten*, we will send a copy of Dr. Nichols' book, "*Chemistry of the Farm and the Sea*," or Messrs. Rolfe and Gillet's "*Handbook of the Stars*," or the "*Handbook of Chemistry*," by the same authors. *These are all beautiful and instructive books.* For *twenty* subscribers, we will send the "*American Naturalist*," published by the Peabody Academy of Science, Salem, for one year. This is one of the most interesting and useful publications in the country, devoted to Natural History. Or a Boy's Tool Chest, 13 inches long, 8 inches wide, 8 inches deep, with a complete set of Carpenters' Tools,—Saw, Plane, etc. (The express charges on the Chest to be paid by the receiver.) For *thirty* subscribers, we will send the *Naturalist* and the "*New England Farmer*," an agricultural paper, published in Boston. For one hundred and twenty-five subscribers, a Silver Case American Watch. Price, $30.

☞ Premiums are allowed only upon *new* subscribers, not on renewals of subscription by old subscribers.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States.

☞ Correspondents are particularly requested to give their names in full, with their Town and State; and, in case of change of residence requiring a corresponding change in the mailing of their papers, to give not only the new address, but the old one also.

☞ Subscribers who are physicians, dentists, or apothecaries will confer a favor by informing us of their profession, as we wish to know accurately the amount of our medical subscription list.

☞ We are unable to supply complete files of either Volume I. or II. of the *Journal*. Of Volume I. (originally issued bi-monthly), Nos. 1, 2, and 3 (July, September and November, 1866), are now out of print. Of Volume II. (monthly), Nos. 1, 3, 6, and 12 (July, September, and December, 1867, and June, 1868), are also out of print. Of the remaining numbers we have a few copies left, which we will forward to our friends at the following prices: Volume I., three numbers, twenty-five cents; Volume II., eight numbers, fifty cents; Volume III., one dollar.

METALS.

Everybody knows that the technical use of a word is often very different from its ordinary application. It means one thing to the scientific man, and quite another thing to people generally. This sometimes leads to misapprehension of the meaning of what we read or hear. One of these words of double signification occurs in a connection where we think we understand it; but it may be that we interpret it in its familiar sense, while it is really used in the less familiar one.

Certain terms much used in chemistry may serve to illustrate what we have said. The word *metal*, for instance, is one which conveys very different meanings to the chemist and to the non-scientific man. The latter associates with it the qualities which are familiar to us in the *true* metals, as they are sometimes called, like iron, lead, tin, copper, gold, and silver. He has no conception of a metal without the metallic lustre, so called, considerable density and tenacity, more or less of malleability or ductility, and the power of conducting heat readily. He is aware that mercury, though liquid, is a metal, and *that* appears to him the one anomalous member of the family. He would be a good deal astonished to be told that the lightest of all known substances, the gas *hydrogen*, is undoubtedly a metal. He would never have thought that a balloon has a metallic filling. But, on account of its chemical behavior, this lightest of gases has long been viewed as virtually a metal; and quite recently its metallic character has been proved beyond a doubt by the English chemist, Graham, who has obtained a definite alloy of hydrogen, and another metal called *palladium*. From the properties of this alloy, he has been able to state pretty definitely what the density, color, etc., of *solid* hydrogen would be; from all which, it appears that it would have some of the familiar metallic properties in a more marked degree than certain solid metals well known to the chemist. For instance, its *density* or *specific gravity*, would be 2; that is, it would weigh twice as much as the same bulk of water. But *lithium*, the lightest of solid elements, is also a metal, with a specific gravity of only .059; that is, it is a little more than half as heavy as water. There are other metals light enough to float on water; as *sodium* and *potassium*. *Calcium* has a specific gravity of only 1.58, and the beautiful metal *magnesium* of 1.75. Aluminium, which is hard, lustrous, and remarkably sonorous, weighs only about two and a half times as much as water; while gold has more than nineteen times, and platinum more than twenty-one times, the density of that liquid.

On the other hand, antimony, bismuth, and arsenic, which have often been classed among metals by chemists, and always reckoned as such popularly, are *not* true metals in their chemical relations, and are now classed by the best writers among the "non-metallic elements."

THE SPECTROSCOPE.

In the last number of the *Journal* we described the spectroscope, and the different classes of spectra with their relations to the luminous bodies giving rise to them. We will now give a brief account of the most important discoveries made by means of this instrument, and especially of its recent revelations concerning the fixed stars and the nebulæ.

Spectrum analysis has led to the discovery of no less than four new metals, whose existence had not been so much as suspected; namely, *cæsium*, *rubidium*, *thallium*, and *indium*. The first two were detected by Bunsen and Kirchhoff, in their examination of the water of a saline spring at Durkheim; the former showing a blue line, and the latter a dark-red line, distinct from those produced by substances previously known. Thallium was discovered by the English chemist, Crookes, while examining the soot of a furnace for burning iron pyrites in the manufacture of sulphuric acid. It shows its presence by a peculiar green line in the spectrum. Indium was detected by Reich and Richter, by certain lines which are found in the indigo portion of the spectrum.

The spectroscope has also given us no little insight into the nature and composition of the photosphere, or luminous envelope of the sun. It has proved that the sun is a solid or liquid body in an *incandescent* or white-hot state, and surrounded by an atmosphere containing the vapors of many metals known to us here on the earth. After what we have said with regard to the different kinds of spectra and their significance, no detailed explanation is necessary to make it clear how this discovery has been made. The solar spectrum is crossed by numerous *dark* lines, called *Fraunhofer's lines*, from their discoverer. Many of these dark lines coincide exactly in position with the *bright* lines produced by certain metals when in the state of luminous vapor. This, as we have seen, is precisely the kind of spectrum which we get when the light of a body has passed through the vapor of other bodies. We infer, therefore, that the sun is an incandescent mass, whose light is partially *absorbed* or quenched by the vapors which surround it; and that among these vapors are such substances as iron, sodium, magnesium, nickel, copper, and zinc. These and several other metals have been identified beyond a doubt by the presence of all their characteristic lines as *dark* lines in the solar spectrum.

The light of the fixed stars has also been analyzed by means of very powerful spectroscopes, and the solar character of these heavenly bodies has thus been demonstrated. A classification of the stars according to the peculiarities of their spectra has been commenced, and

is rapidly becoming perfected. They can nearly all be grouped in a few families, corresponding in the main to the more obvious characteristics of their light. Thus, the *red* stars are found to be related not only by the color of their light, but by the general nature of their photospheres, as indicated by the substances vaporized therein. We may recur to this point at a future day.

Under certain conditions the spectrum of a star may tell us whether the body is *moving* towards or away from the earth. We know that many of the stars are in motion; for, although we call them "fixed," careful measurements prove that their relative positions are not exactly the same from year to year. Their *proper motion*, as it is called, is to our eyes exceedingly small, and the observations of years have been required to detect it; but in the case of many stars it has been accurately measured. It is obvious, however, that, unless the motion is *transverse* to our line of vision, it cannot be detected in this way. If the star is moving directly towards the earth or directly away from the earth, it will appear to be stationary. We might at first suppose that, if the star were thus coming nearer or receding, we should know the fact by the increase or the diminution of its brightness. But the stars are at such immense distances that a motion of many miles in a second, for many years, would make no difference in their brightness which would be detected by the eye, or even by our instruments for measuring the intensity of light. Besides, the transparency of our atmosphere is subject to many variations, and the light of many stars is known to be variable. But here the spectroscope comes to our aid.

Color has been found to depend upon the *length* of the waves of light, or, since they all have the same velocity, upon the *number* which fall upon the eye, or upon a prism, in a second of time. The waves of red light are nearly as long again as those of violet light, but the velocity of both is about 185,000 miles in a second; so that a series of waves of that length enters the eye in a second. Anything which would alter the length of the waves *with relation to the observer*, or, in other words, would cause a larger or smaller number of waves to enter the eye in a second, would cause a change in color. Now, it is obvious that the velocity of the light is virtually altered to an observer who is moving in the direction in which the light is travelling. If he moves *towards* the light, a larger number of waves will enter the eye in a second; if he moves *away* from the light, fewer waves will enter the eye in a second. It does not matter, of course, whether it is the observer or the star that is moving; the effect will be the same.

Certain phenomena of *sound* illustrate the same principle. The pitch of sound depends upon the *rapidity* of the vibrations, or the number reaching the ear in a given time. If the sounding body is rapidly approaching us, the pitch of the sound will rise, since the vibrations will enter the ear faster; while, if it is swiftly receding, the pitch will fall. Every one has probably noticed such changes of pitch in the sound of a locomotive steam-whistle, though he may not have understood the cause.

Light moves so much faster than sound (the latter having a speed of only 1,090 *feet* in a second), that a luminous body must have a velocity of twenty or thirty miles a second, in order that its motion towards us, or away from us, may produce a change of color sufficient to be detected by the most powerful spectroscope.

Our limits will not allow us to give even an outline of the method by which the result has been obtained (though there is nothing about it which could not be explained in a familiar way, if we *had* the space); but changes in the color of Sirius have been detected by the spectroscope, and have been proved beyond a doubt to be due to the fact that its distance from the earth was at the time *increasing* at the rate of about forty-one *miles a second*. This does not, however, give the exact rate at which the star is moving away from us. The earth itself has a velocity of nineteen miles a second, which at the time when these observations were made was in such a direction with reference to Sirius that we must cut the forty-one miles down to thirty. Again, our whole solar system is moving at the rate of four or five miles a second away from Sirius, reducing the thirty miles to about twenty-six. We have also to take into account the *proper motion* of the star, which proves that it is moving not *directly* but *obliquely* away from us. After making this final correction, we come to the conclusion that the true velocity of Sirius is twenty-four miles a second, if we adopt the smaller of the distances which different astronomers have assigned to the star. If we take the distance obtained by other calculations, the velocity will be forty miles a second.

We can add but a word now concerning the other revelations of the spectroscope, of which we intended to give an account. The instrument has done much to give plausibility to the nebular hypothesis by proving that, while many of the nebulæ are made up of multitudes of stars, so distant that their light blends in a mere luminous whiteness which cannot be resolved into separate points, there are many others which are nothing but enormous *masses of luminous gas*, in which we can detect hydrogen and nitrogen by their characteristic lines. It has also begun to tell us something of the nature of *comets*, the physical constitution of which has been as great a mystery to the astronomer as their sudden appearance in the heavens has been to the uneducated. The spectrum of a small comet, which was seen last year, was found to agree exactly with one of a series of spectra of *carbon*, obtained by Mr. Huggins, showing that the comet consisted of carbon in a state of vapor.

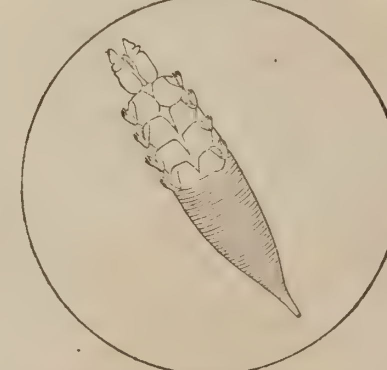
Very recently the spectroscope has been applied to the examination of the spots on the sun, and of those singular protuberances of various forms, and of a reddish light, which have been seen about the edge of the sun at the time of total eclipses. They are invisible at other times, on account of the imperfect transparency of our atmosphere; but their spectra can nevertheless be obtained and examined. We may expect that these and other investigations made with the aid of this wonderful instrument will ere long add largely to what we know about the sun.

ANOTHER PARASITE IN THE PIG.

The occasional presence of trichina in man and the pig is well known, but this community of parasitism is not confined to the trichina. Not long ago a portion of pig's flesh and skin was sent to that most indefatigable microscopist, Dr. J. H. Salisbury, of Cleveland, O., for examination under the supposition that it contained trichinæ. It had small, hardened, whitish nodules buried in the substance of the skin and flesh. Dr. Salisbury found that these masses were conglomerations or colonies of a parasite entirely distinct from the trichina, but well known as a human parasite which inhabits the sebaceous and hair follicles, particularly of the nose. It is called the *steatozoon folliculorum*, synonymes *demodex folliculorum, entozoon folliculorum, simonia folliculorum.*

These animals may be obtained by pressing out the contents of one of the nasal follicles, especially when these appear enlarged, whitish, and exhibit a terminal black spot. Topping found a species of this parasite in the pustules of the skin of a dog affected with the "mange," of which it appears to constitute the essence, as Gruby found that a disease, similar if not identical with the "mange," was produced by inoculating the dog with the human parasite.

The discovery by Dr. Salisbury of the *steatozoon folliculorum* in the pig adds to our knowledge, and the query may be raised whether man may not have derived this parasite from the pig. The fact of the very large number found in the portion examined, compared with their fewness in man, seems to indicate a more favorable nidus in the lower animal. The accompanying cut represents a female steatozoon, drawn from one of the original specimens discovered by Dr. Salisbury. It is magnified about five hundred diameters.



The application of this is to have pork thoroughly cooked, if you would avoid the parasites of the pig. A temperature of 212° Fahr. coagulates albumen. When this is done, the germ and protoplasm are destroyed.

"SUNLIGHT OIL" AND POTATOES.

An enterprising quack out West has discovered a new use for potatoes. He employs them in the manufacture of a new "sunlight oil," the formula for making which, and the "right to use," he is busy in peddling to the good people of Columbus, Ill. One of the "victims" sends us his "family right," for which he paid *two dollars*. We give the recipe for the benefit of our numerous readers:

"To make one gallon, take three quarts of *naphtha*, one and one-half ounces alum, two ounces of cream of tartar, two ounces sal soda, *one pint of potatoes* cut fine, two tablespoonfuls of fine salt, two drachms gum camphor; mix and shake, and the 'oil' is ready to use in two hours."

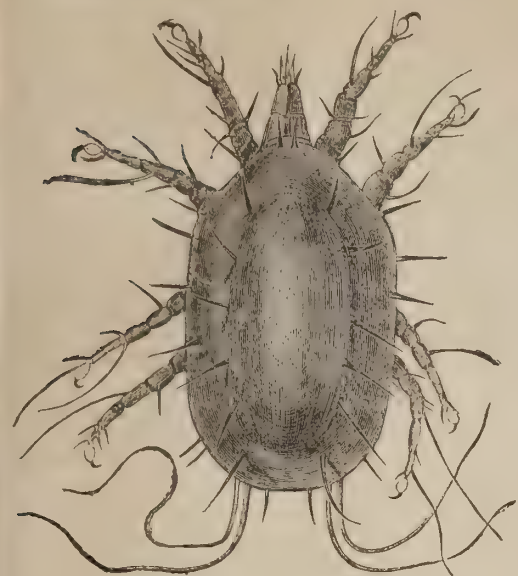
We hardly know which to admire most, the cool impudence of "*M. Wagner & Co.*," who sell the recipes, or the extreme simplicity of purchasers who buy them at two dollars each. Now we can save those desiring to purchase the formula for making "sunlight oil" all this expense and trouble. Our formula is as follows:

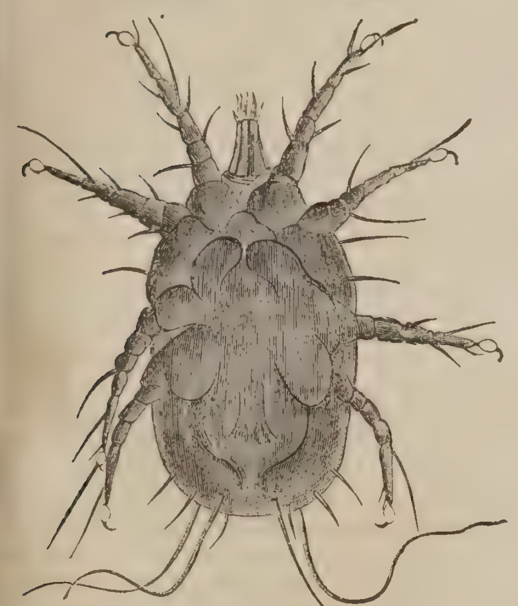
TO MAKE "SUNLIGHT OIL."

Take three quarts of naphtha, one quart of clean sand; mix, and the "oil" will be fit to use instantly. If sand cannot be procured, pebble-stones, or *buckshot*, will answer just as well.

These substances are as readily *soluble* in naphtha as *potatoes*, cream of tartar, alum, or sal soda, and will render the naphtha just as "inexplosive"; and they have the advantage of being capable of being used "over and over again." We most sincerely hope no reader of the *Journal* is deceived by the villains who are travelling over the country selling "rights" to make and use "sunlight" or any other kind of naphtha "oil."

THE SUGAR INSECT.





In the essay, "Chemistry of a Lump of Sugar," in the May number of the *Journal*, some statements were made regarding certain disgusting insects common to raw or unrefined sugars, and the promise was made to present, from microscopic drawings, engravings of the *acarus sacchari* for the benefit of our readers. The promise is redeemed in this number, and two large figures, the first representing the under side and the second the upper side of the insect, are given. The cuts present them accurately, as magnified about two hundred diameters. They are not pleasant creatures to look at, and yet it must be remembered that nearly or quite all the impure or dark-brown sugars sold by grocers are crowded with them. Dr. Hassel, of London, examined seventy-two specimens of these sugars, and found the insects in sixty-nine of them. He estimates that every pound of the cheap Muscovado sugar contains no less than 40,000; and Dr. Barker states, as the result of his investigations, that some specimens contain 268,000 in the pound. They are found in the brown and white Havana sugars, so largely sold and used in every town in the United States, and in some qualities they are very numerous. In wet sugars, containing much molasses, they are often present. They cannot exist in refined sugars, as they feed upon nitrogenous impurities not present in those kinds. The consumption of sugar containing these insects must prove detrimental to health, and therefore the refined sugars should be substituted for the unrefined in families

INTESTINAL WORMS.

We are pleased to notice that the views first presented through the *Journal*, regarding the place of deposit of the ova of *Oxyuris vermicularis* in the alimentary canal, have received the sanction of so distinguished an observer and physician as Prof. Zenker, of Erlangen. He was the first to observe and recognize trichina disease in the living subject, and may be regarded as the highest living authority upon all matters pertaining to parasitic animals in man. In his recent report to the Congress of German Naturalists and Physicians, he states that "the ova of pin-worms *are only set free in the rectum, near the anus*, or after the worms have been discharged from the bowels." Any physician can verify this by taking a piece of silk or linen, and passing it across the external orifice of a child suffering from pin-worms, and examining the surface of the cloth with a lens of thirty or forty diameters. Hundreds of the minute white ova can be seen by the most inexperienced observer. As regards the use of lard or other fats as a remedy, externally applied, we can only say that its entire success is vouched for in numerous cases by physicians and others, and it is worthy of fair, extended trial. The parasite is exceedingly common, and very troublesome and vexatious; and, if the value of so simple and cheap a remedy is fully established, it will indeed prove a boon to thousands of suffering children and adults. It is probable that the application should be thorough, and the surfaces of the spinchter muscle fully anointed.

☞ The *Manufacturer and Builder*, published by Messrs. Western & Co., N. Y., one of our most interesting, substantial and valued exchanges, contained in the June number a prominent paragraph, which, as it relates to statements made in the *Journal*, we copy, and append to it some comments:

"A Poor Prospect for the Year 1900.

"The *Boston Journal of Chemistry* lately gave us a glowing account of the wonders which were to be brought to light ere the year 1900 shall appear as the date of our letters and periodicals. All our old systems of lighting, heating, and producing power are to be modified, or superseded by different and far superior methods. And yet, in a recent number, the editor gravely tells us that '*there is not, nor can there be*, any oil or liquid substance devised, suited to household illumination, which is cheaper, safer or better than well-manufactured kerosene of legal standard.' The italics are his own."

Well, what of it? The statements are perfectly correct and consistent. Is it probable or *possible* that in the future we shall discover or devise any *oils* or *liquid* substances suited to household illumination *cheaper* or *better* than the products of distilled petroleum? We think not. Petroleum is a rich hydro-carbon liquid, a product of nature, stored up in the earth in such vast quantities that, when a way of escape is provided through artificial openings, all our energies are taxed to secure it. Certainly, nothing of *the kind*—that is, no *oils* or *liquid* substances from which light can be obtained—will ever be supplied to us at less cost, or which can prove safer or better. This being true, it does not follow that no improvements will be made in light-producing materials or agencies in *other directions*. We certainly have good grounds for believing that, within the next thirty years, methods of artificial illumination will be discovered so good and cheap that even the petroleum products will fall into disuse. The gaseous bodies and electrical forces offer promising fields for research, and so we conclude that the "prospect for the year 1900" is not very "poor" after all.

SOMETHING NEW.

The cuts with which we illustrate the articles on the sugar insect, and the new insect found in pork, are stereotyped from regular *castings* made by the Metallic Compression Casting Company of this city. It is the first time any journal has ever been illustrated by cuts cast from metal after the new method. Upon examination it will be seen that all the fine lines are brought out with much distinctness, and the cuts are as clear as are afforded by the electrotype process. By this method the most beautiful and perfect castings are rapidly made, and the new art promises to be of the greatest utility. The two principal points of interest in the invention are the use of *fine potters' clay* instead of sand for the mould, and the injection of the molten metal at the *bottom* under *great pressure* by a piston moving in a cylinder. The progress of art and invention was never greater than at the present time, and every month almost we are astonished and delighted with new discoveries brought to our notice.

☞ One of our advertising patrons writes as follows: "I am well satisfied with the advertisement in the *Journal*. It has evidently *gone into every nook and corner* of our country, as we have letters of inquiry from all sections. The advertisement of our Medical College *has certainly reached more physicians* than it could through any other channel." No doubt of this. Every number of the *Journal* is read by *more than ten thousand* M. D.'s who are regular subscribers, residing in every State and territory of the Union, from "Maine to Georgia," and from Alaska to Texas. They, however, constitute *only one class* of our numerous family of readers.

☞ When a subscriber to the *Journal* sits down to write a letter to the editor making numerous inquiries, and soliciting some service which it would require time and thought to render, he must remember that he is not alone in the work. At the same time, ten, twenty, thirty, perhaps fifty, other subscribers in the North, South, East and West, are also writing letters of a like nature, and these communications will reach us in the same mail. However much we may desire to oblige our correspondents and friends, it will be seen at once that it is *impossible* to respond to all, or even one-half, of the letters of inquiry. We have no objection to receiving and examining these letters, so far as time will permit; but our friends must not regard us as wanting in courtesy if no response is made.

BOOK NOTICES.

Spectrum Analysis: Six Lectures delivered in 1868 before the Society of Apothecaries, of London. By Henry E. Roscoe, B. A. F. R. S. London: Macmillan & Co. 1869.

This book, sent to us by the eminent book-publishing house, Macmillan & Co., London, is not only a beautiful specimen of English typography, but of the chromo-lithographic art also. The spectra of the metals of the alkalies and alkaline earths presented, as made from the drawings of Bunsen and Kirchhoff, are wonderful examples of chromo coloring, and are as accurate as they are beautiful. Prof. Roscoe, in the treatise, has endeavored to present elementary principles, and at the same time afford a complete view of the science of spectrum analysis. Of course, a science in such a rapid state of growth can only be kept up with by a careful reading of the foreign and domestic scientific journals, as they appear from month to month: but in this work the general reader will find everything essential to a clear understanding of the subject; and he will find exact copies of Kirchhoff's, Angostrom's, and Huggins's maps, together with the tables of the positions of the dark solar metallic lines, which are of the highest interest. Our readers, who do not care to make extended

study of this new and wonderful science, will find in the articles now appearing in the *Journal* all the prominent facts and results attained up to the present time, presented in a plain and familiar manner.

HANDBOOK OF NATURAL PHILOSOPHY, for School and Home Use. By W. J. ROLFE and J. A. GILLETT, Cambridge. Woolworth, Ainsworth & Co., Boston. 1869.

Messrs. Rolfe and Gillett have done a good service to the youth of our country by placing in their hands treatises upon the natural sciences so clear, accurate and attractive as this "Handbook," and the others which constitute the "Cambridge course" of studies upon the sciences. This series of books is *admirable*, both in matter and illustration. Whilst careful, in example and statement, to maintain the true dignity of science, they have succeeded in throwing around philosophical subjects a charming simplicity and attractiveness; and the language employed is chaste, accurate, comprehensive. The Handbook of Natural Philosophy is well adapted to household reading, and the experiments are easily performed and understood. The publication of such treatises leaves but little to be desired in the way of text-books for schools, or books for family reading, upon the natural and physical sciences.

HALL'S ALPHABET OF GEOLOGY; OR, FIRST LESSONS IN GEOLOGY AND MINERALOGY. By S. R. HALL, LL.D. Boston: Gould & Lincoln. 1868.

This little work is, in some respects, to be commended. It affords to the general reader a summary of the principal facts connected with geological science, and it has the merit of succinctness and plainness of statement. We do not altogether like the plan or arrangement of topics, and fear the book is not sufficiently attractive, or that it will not infuse into the reader a sufficient amount of enthusiasm to lead to attentive study. It affords evidence also that the writer is not a practical geologist, but an amateur who has read some popular works upon geology, and has attempted to compile a book upon the basis of that kind of reading. There are too many works of the kind printed in this prolific book-making age.

WATCH-REPAIRER'S HANDBOOK; being a Complete Guide to Young Beginners in Watch-repairing, etc. By F. KEMLO, Watchmaker. Boston: A. Williams & Co. 1869.

A beautiful and interesting little book, which must be of special service to all interested in watch making and repairing. It presents a history of watch-making, both in Europe and this country, and gives directions how to select and keep in order timekeepers. The elegance of typography, and the beauty and clearness of the illustrations found in this book, reflect great credit upon the publishers.

Medicine and Pharmacy.

A NEW METALLIC SUTURE.

BY EPHRAIM CUTTER, M. D., BOSTON.

Editor Boston Journal of Chemistry:

Instead of threads of linen, cotton and silk, the surgeon prefers those of gold, silver, copper, or iron, because the former act like setons, and become centres of purulent irritation. A metallic suture absorbs nothing, and is borne well by the most sensitive and delicate tissues. An objection to metallic sutures arises from the fact that they are difficult to introduce. If an ordinary needle is employed, there is an unpleasant hitch at the eye caused by the loop which is formed by the bend of the wire. Three elements form this loop: First, the wire; second, the end of the needle beyond the eye, and between the two parts of the suture; third, the wire again. The same elements are present in the iron metallic suture, but the soft, yielding nature of the silk, cotton, or linen allows of an easy compression of the loop, so that the hitch is practically avoided. Not so in the metallic suture. Its unyielding nature allows of no such compression: hence it must be forced through, tearing its way, and making a hole much larger than is necessary. Hitherto this difficulty has been met by making the needle so large that the loop would be embraced in grooves in the needle, as in Lister, of Glasgow. Another way is to have a hollow cannular needle pointed, the suture lying within the hollow. The difficulty with these methods is that the needle is too large. The ideal, then, is to make an orifice of insertion of the same size of the suture. The diameter of the insertion wound being thus accurately filled by the suture, the parts can be approximated with the greatest precision. To carry out this idea it would only be necessary to sharpen the end of the suture and introduce it. But this is impossible from the necessary flexibility of the material.

It occurred to the writer to *solder* the needle *directly* to the wire. The needle used is the ordinary three-sided one, and its diameter bears a close relation to the diameter of the suture.

CODMAN & SHURTLEFF, BOSTON

It was found difficult to make them, but the instrument makers whose name is on the cut have surmounted the obstacles, and furnish an article of superior work. Silver is the best material for ordinary use. They are made of all sizes, from the large copper sutures for autopsies down. The writer can speak from experience of the satisfactory use of these sutures, which have no hitch. He is permitted to refer to Dr. L. Elsburg, the eminent laryngoscopist, of New York, and Dr. J. Solis Cohen, his worthy confrère, of Philadelphia, for commendation of their use and efficiency.

MAY, 1869.

DIPHTHERIA AND ITS RELATIONS TO MEMBRANOUS CROUP.

At a recent meeting of the Essex North Medical Society of Massachusetts, Dr. John Crowell read a paper upon the above subject, of which a brief abstract is presented below:

In its pathology, diagnosis and principles of treatment, diphtheria may be ranked among the modern diseases. Yet, from the writings of old physicians, we are certain that it existed and prevailed extensively at different times in the 16th, 17th and 18th centuries. It broke out in epidemic form in France in 1818, and was described by Butormeou under the name of diphthérin, in Mémoires communicated to the "Académie Royal de Médicin," in 1821. About the same time also, some cases seem to have occurred in Scotland, and a few in England and in this country. But only slight attention was given to the subject until the outbreak of the epidemic at Boulogne, in January, 1855.

In England, the first epidemic cases were minutely observed in the year 1856, and the attention of the profession was directed to the disease in this country at about the same date.

We speak of the disease in its distinctive and positive character, as it invades the soft parts of the throat with the peculiar grayish-white, leathery exudation, invading the system with its poisonous influence. No portion of the mucous surfaces is exempt from the exudation. It may be formed on abraded cutaneous surfaces, on the conjunctiva, on the vaginal mucous coat, or the lining membrane of the rectum. Under the microscope, the diphtheritic exudations will be found to consist of molecular particles, epithelium, pus cells and blood corpuscles. Fibrillæ are but rarely seen. The *oïdium albicans* may occasionally be detected, but the occurrence of this fungus is only exceptional, and when the membrane has begun to undergo an acid putrefaction.

The most insidious phase assumed by the disease is when the air-passages directly communicating with the lungs become involved, producing the physical signs peculiar to laryngitis, bronchitis, congestion and membranous croup.

Dr. C. cited five cases that had come under his observation where the local signs of diphtheria had disappeared, and the patients were apparently convalescent, when all the physical signs of membranous croup suddenly supervened, resulting in death from asphyxia in each case.

The general principles of treatment were then discussed, reference being made to the plan adopted by Dr. Cox, of Ohio, during the prevalence of the disease in epidemic form in several sections of that State, a few years since. This *sustaining* treatment is now generally adopted by the profession.

When the exudation invades the larynx, producing the croupy complication, the treatment indicated is similar to that adopted in membranous croup. The authority of Dr. George Buchanan, of the Royal Infirmary, Glasgow, was cited in favor of tracheotomy in all cases where it would be justifiable in membranous croup. Dr. B. has saved about one-third of the cases operated on in this form of the disease.

Dr. Bennett, in his valuable "Clinical Practice," strongly advises the adoption of the method of Dr. Horace Green, of New York, of applying topical remedies directly to the fauces, larynx and trachea. Dr. E. Nutson, of Glasgow, and Dr. Bennett, have both employed this method with good results.

Strong solutions of argent. nit. are used, as these act chemically on the mucous, pus, or other albuminous fluids they come in contact with, throw down a copious white precipitate in the form of a molecular membrane, which defends for the time the tender mucous surface or irritated ulcer, and leaves the passage free for the act of respiration.

The conclusions deduced from this argument were,—

1st. "That the diphtheritic exudation, invading the larynx and trachea, produces physical results similar to those of membranous croup."

2d. "That *practically* there is no essential difference in the pathology of the two diseases."

3d. "The principles of treatment in both conditions are identical in their practical application."

In the discussion which followed the reading of this paper, the opinion of Dr. J. R. Nichols was called for in regard to the relative chemical analysis of the membranes formed by the two conditions of disease. Dr. N. remarked that he was not prepared to give an accurate analysis of the diphtheritic exudation, but he felt convinced that it was wholly unlike that of membranous croup,—the former being albuminous, and subject to speedy decomposition; while the latter was fibrinous and more tenacious, and unyielding to the inflammatory action. He did not like the term "diphtheritic croup," as diphtheria and croup were entirely distinct diseases, the former to be classed as *zymotic* in its nature, the latter not.

Dr. Garland contended that the physical signs in the croup complication of diphtheria were unlike those of true croup; that the patient died of exhaustion rather than by asphyxia. According to his observation, the croupy signs in diphtheria ceased before death, whereas in true croup they continue to the last. Croup is a disease peculiar to childhood; diphtheria, in all its phases, attacks all ages. Diphtheria is confined more especially to the poor and destitute, and dependent upon local causes; croup attacks families in the most favored localities, and seems to have no relation to local causes. Dr. Howe was of the opinion that the croup, in diphtheria, was simply accidental, and had no pathological relation to the disease.

Dr. Drinkwater contended that whatever produced the physical phenomena of croup might properly be called croup. He would call the croup of diphtheria membranous croup, although the chemical structure of the two membranes might be unlike.

This view was favored by Drs. Flint and Johnson.

The discussion was continued to some length, and the facts adduced in illustration of the positions were interesting and instructive.

TREATMENT OF LEAD-POISONING. — Dr. William Frank-Smith states (*Lancet*) that, in lead-poisoning, the treatment by iodide of potassium has been less efficacious in his practice than that by sulphuric acid and the sulphates. The formula used by him, which acts, he says, "with remarkable celerity and certainty," is as follows: Sulphate of quinine, sulphate of iron, of each one grain; strychnia, one thirty-sixth of a grain; dilute sulphuric acid, five minims; sulphate of magnesia, one drachm; water, one ounce: three times a day.

SUBSTITUTE FOR DOVER'S POWDER.

A correspondent of the *Medical and Surgical Reporter* remarks as follows of a valuable diaphoretic powder:

The late Dr. Brinsmade, of this city, a short time before his death, substituted sugar for liquorice-root in preparing Tully's powder, very much to his satisfaction, and in his modest way mentioned the fact to a very few of his most intimate friends, from whom it gradually spread. All once using this form continued to do so. The addition of sugar renders this powder readily miscible in water, and the most convenient form for administering small doses of morphia, especially to children and persons of delicate stomachs, within my knowledge. As Dr. Tully's name has become inseparably associated with his modification of Dover's powder, I have ventured to send the annexed formula, and call it

DR. BRINSMADE'S DIAPHORETIC POWDER.

℞. Morphiæ sulph. ʒj.
Camphor,
Cretæ prep.
Saccharum, aa. ʒxx.
Misce (intimately).

Of this, ten grains contain very nearly one-sixth of a grain of morphia; and any person who tries that quantity in a teaspoonful of cold water will at once realize its eligibility over any other anodyne powder.

MILK FOR INFANTS.—There can be no doubt that it was intended that every infant should have the milk of its own mother to nourish it; but sometimes this cannot be had, and then we are compelled to use another kind. Whenever infants are fed with milk, it should always be of the purest kind, and drawn each morning and evening from the cow. When this can be had, it should not be given until it is made more like human milk, by adding a little loaf sugar to it, and about one-third or one-fourth of water. The water should be hot, and the sugar dissolved in it; then slowly pour it into the milk, and allow it to simmer just a little over the fire. If you scorch it in the least, throw it out.

This is the way you do in the morning with the fresh milk, which is to last until evening; and at night you must do so again with the evening's milk, which is to last until morning. A very good vessel to keep the prepared milk in is a stone bottle, such as mead has come in, which should be put into the best order with soap and plenty of hot water. It is better than a tin can, and costs but a few pennies.

If you do not *know* that the cow's milk is of full strength — and you will find very little that is, in a large city like this — it may be better if you add no water at all, or, at least, no more than enough to dissolve the sugar.

What is better than the ordinary milk, such as we get in the stores or out of wagons, is the milk of the common goat, which can always be had, fresh, in this part of the city (the south-western), all the year round, every night and morning, with but little trouble and at small expense. Not only has it these advantages, but it resembles human milk more than does that of the cow, so much so, that it requires no sugar and but little water. Many physicians, who have seen both kinds used, have learned to prefer the milk of the goat to that of the cow. When brought home fresh in the morning or evening, it should be heated to a gentle simmer, cooled and then put away into the stone bottle, closely corked with a nice, clean cork, and kept in a cool, dark cellar.

When an infant is to be fed, do it in this way: have a cup and spoon, which should never be used for any other purpose whatever; scald them in hot water, and then pour into the cup as much of the prepared milk as you think the infant should use at once. If it uses a bottle instead of a cup, you should be *very* careful that it has been thoroughly cleansed and scalded, especially about the neck and nipple. After the wants of the child have been satisfied, what is left in the cup or bottle should be thrown out, especially during the hot weather, and milk fresh from the stone vessel used the next time. The bottle, or cup and spoon, should now be washed in hot water, then scalded and allowed to stand awhile in the sun. If the infant soon needs more food, have another cup and spoon which can be used, and, after they are used, go through the same trouble again with them —if you call it trouble. If you do not give everything this care, the infan may become ill, and you will have a great deal more of a different kind of trouble, and run the risk of losing the little one besides.

If possible, get the milk fresh every morning and evening; and this can be done if you use that of the goat. If at any time you find that the "child's stomach turns," as the saying is, after taking the milk, you may be quite sure that the trouble is *want of neatness*, which "turned" the milk a little before the child swallowed it. A trifling thing about the milk, which the mother's sight or taste cannot detect, may not only make the infant sick, but disturb its health for several days. If the vomiting continues, take a tablespoonful of lime-water and add it to a tablespoonful of cold water, and give it to the infant as a drink, between the times of nursing. If the vomiting still continues, take the child to some physician, and ask him where the trouble is.

Dr. W. K. Bowling, of the *Nashville Journal of Medicine and Surgery*, is one of the few "jolly writers" on the solemn subjects of "physicians' fees," "ingratitude of patients," "delinquent patrons, etc.," and draws "fun" from all such topics, as the bee sucks honey from the freshest clover-blossoms. Read the following description of his method of "charging" his patients:

"'Do you charge anything for this?' said a substantial countryman, eyeing the hieroglyphics upon a prescription paper we had handed him after we had thumped every rib in his body and every vertebra in his backbone, placed the bulb of a thermometer under his tongue and made a note of its revelation, and, with equal care and accuracy, secured the temperature of both axillæ; had placed a drop of his blood under a microscope of three hundred dollars' power, and written down what it said, besides with gaslight, bull's-eye and laryngoscope illuminating his 'interior basin' down to his umbilicus; while all the time our steam atomizer was 'going it' at a white-heat, its alcohol under a consuming fire, and the inevitable and everlasting carbolic acid going to waste, hissing, sighing and singing, and calling to mind the oft-repeated order of poor Barnaby Rudge's raven of 'Jenny put the kettle on, we'll all drink tea,' and all as if the unconscious machine was rejoicing in anticipation of a victim.

"'Charge?' we echoed interrogatively. 'No, sir, oh, no!' And we said it in a voice softened and modulated to the very sweetness of melody. (We had acquired the trick at an old-field la, me, fa, sol singing-school when a boy.) 'Charge?' we repeated with an intonation as dulcet as the musical fall of a dewdrop from the willow into a silver basin, in the atmosphere of a Hannah Morean moon whose light could be sliced by a golden knife. 'No, sir. We formerly did so; but the expense of book-keeping, and the added per cent upon those who paid to secure us against losses from those who didn't, made the charging system (excuse us a moment till we extinguish this lamp),—made the charging system a punishment to the honorable and a blessing to rogues, thus reversing a law of Heaven. No good man could be guilty of so revolting a sin after it was pointed out to him, and of course we quit charging. For our expenditure of skill upon your case this morning, you only have to pay me ten dollars, which, under the abrogated and consequently obsolete rule of charging, would have been twenty. So you see, my dear sir, that you save ten dollars by this new system of charging nothing, and taking pay as we go. As he handed us the X, he said he had no doubt that the new rule was the best for all parties. 'Except the rogues,' said we. 'In course,' he assented, 'except the rogues.'"

A NEW SOURCE OF LEAD-POISONING. — Our attention has been called by Mr. Corner, of Poplar, to some cases of lead-poisoning that have recently occurred at newly-fitted public houses in this district, and that have been traced to morning draughts of the beer that had been standing all night in the leaden pipes of the beer-engines. It is also said that experienced publicans, instead of serving this poisoned beer to their customers, draw it off and return it the brewers, who make them an allowance for it. What becomes of it then? — *Lancet.*

A CURE FOR HEADACHE.

BY GEORGE KENNION, M. D., F. R. C. P., HARROGATE.

The remedy, as I have already observed, is simple; it is the bisulphide of carbon in solution. Its mode of application is no less simple. A small quantity of the solution (about two drachms) is poured upon cotton wool, with which a small, wide-mouthed, glass-stoppered bottle is half filled. This, of course, absorbs the fluid; and, when the remedy has to be used, the mouth of the bottle is to be applied closely (so that none of the volatile vapor may escape) to the temple, or behind the ear, or as near as possible to the seat of pain; and so held for from three to five or six minutes. After it has been applied for a minute or two, a sensation is felt as if several leeches were biting the part; and, after the lapse of two, three, or four minutes more, the smarting and pain become rather severe, but subside almost immediately after the removal of the bottle. It is very seldom that any redness of the skin is produced. The effect of this application, as I have said, is generally immediate. It may be applied, if necessary, three or four times in the day.

The class of headaches in which this remedy is chiefly useful is that which may be grouped under the wide term of "nervous." Thus neuralgic headache, periodic headache, hysterical headache, and even many kinds of dyspeptic headache, are almost invariably relieved by it; and, although the relief of a symptom is a very different affair, of course, from the removal of its cause, yet no one who has witnessed (and who of us has not seen?) the agony and distress occasioned by severe and repeated headache but must rejoice in having the power of affording relief in so prompt and simple a manner. — *British Med. Journal.*

CARBOLIC ACID. — Crystallized carbolic acid becomes *liquid* in warm weather, and solidifies again as winter approaches. The best acid assumes a pinkish hue (which is due to the action of light) by long keeping, but this in no respects renders its use inadmissible for the nicest purpose. We have had thousands of pounds, which as it flowed from the retorts and crystallized was white and beautiful as the freshest snow, change in the course of twenty-four hours so as to have some color. No specimen from the best European makers, that we have seen, is free from this liability. Redistillation, a dozen times repeated, does not always suffice to maintain it in a colorless condition for many months.

SUNSTROKE. — Sunstroke, like hydrophobia, is always a doubtful subject as to what it really is, and how caused. The forms of medical treatment in the case of sunstroke are as varied as the theories advanced of the character of the malady.

In England, such cases are considered as arising from direct over-heating of the blood, and treated accordingly. At home some doctors consider it a poisoning of the blood, and follow a treatment analogous to that in snake-poisoning. Indian doctors believe that sunstroke is occasioned by the direct action of the sun's rays upon the hair, or perhaps upon the *medulla oblongata.* But how is this effect caused? What rays of the sun thus affect? It cannot be the illuminating rays, nor can it be the heat; for firemen, puddlers, glass-blowers, etc., endure much greater heat, and at still greater disadvantage. But in the solar rays we have the "actinic" or chemical rays, and it is the actinic which acts most powerfully on organic nature; and the actinic rays are surpassingly energetic in the tropics. — *Engineering and Mining Journal.*

Dr. A. P. Dutcher recommends, in the *Cincinnati Medical Repository*, for spinal irritation, the application of a succession of small blisters to the spine, and the following prescription:

℞ Ext. cannabis indicæ . . . . ʒ ss
Quiniæ valerian. }
Ext. scutellariæ } . . . . aa ʒ j

M. — Thirty pills. *S.* — One pill every five minutes.

SULPHITE OF SODA IN CHRONIC CYSTITIS. — Mr. L. Willcox, late house-surgeon of King's College Hospital, recommends the use of sulphite in those cases of chronic cystitis where the urine decomposes before it is eliminated. He finds that by the employment of sulphite of soda all the putridity disappears, and the urine becomes clear and colorless. — *The Practitioner, and Canada Med. Jour.*

Dr. Taylor, in the *British Medical Journal*, urges the employment of iron in the form of ammonio-chloride, and not in the form of the muriated tincture, in *dropsy.* The ordinary dose of the perchloride is to be added to a drachm of the liquor ammonia acetatis, this being previously acidulated by a few drops of acetic acid.

A citizen in Brunswick, Me., who earns his living working by the day, has paid for morphia, for the use of his wife, nearly thirteen hundred dollars during the past fourteen years. The woman declares that she cannot live without this stimulus, and her husband once walked twenty-four miles to get her usual supply.

CINCHO-QUININE.

Cincho-quinine results from a series of experiments upon the cinchona barks, undertaken in our laboratory with the view of presenting the medicinal alkaloidal principles in an equally efficient but pleasanter and cheaper form than sulphate of quinine. This desirable end has been accomplished. It is manufactured from a mixture of the finest varieties of the Loxa and Calisaya, or the pale and yellow Peruvian barks, and no substance or ingredient but what exists naturally in these barks enters into its composition. The crystallizable, alkaloidal principles of these barks, upon which their therapeutic influence depends, disassociated from mineral acids, constitute cincho-quinine.

It presents the tonic and febrifuge properties of bark in their most pleasant, direct and natural form, and is adapted to replace sulphate of quinine, and is preferable to that salt from the following considerations:

1st. It exerts the full therapeutic influence of sulphate of quinine, in the same doses, without oppressing the stomach or creating nausea. It does not produce cerebral distress, as sulphate of quinine is apt to do; and, in the large number of cases in which it has been tried, it has been found to produce much less constitutional disturbance.

2d. It has the great advantage of being nearly tasteless. The bitter is very slight, and not unpleasant to the most sensitive, delicate woman or child.

3d. It is less costly than sulphate of quinine. Like the sulphate of quinine, the price will fluctuate with the rise and fall of barks, but we shall supply it at all times at less than the lowest market price of that salt.

Cincho-quinine we present in the form of snow-white crystalline flakes, easily reduced to powder by rubbing, and perfectly soluble in weak acidulated water. It is placed in vials holding each one ounce, of the same size and form of those holding sulphate of quinine. No directions for its employment are needed, as it may be used in the same quantities and forms and for the same affections as sulphate of quinine, so fully understood by every physician.

Any physician in the United States, by enclosing four three-cent stamps to our address, will receive by return post a specimen of cincho-quinine sufficient for satisfactory trial.

JAS. R. NICHOLS & CO.

Sulphate of Morphia.

We are prepared to supply *Sulphate of Morphia* of our brand in its purest form, put up in ⅛ oz. vials, 8 in a box, in any quantity that may be desired. Also all the other alkaloidal and acid principles of opium.

Sulphate of Morphia.	Acetate of Morphia.
Muriate of "	Valerianate of "
Bimeconate of "	Codeia.
Pure Alkaloid.

TERMS, NET CASH.
Bank Draft or P. O. Money-Order to accompany the order.

For the convenience of small dealers, we present below prices of our chemical products, in small quantities, such as are often wanted. For prices in packages, or in large quantities, see our regular monthly Price-List.

PRICES OF VIALS AND BOTTLES.—g.s.v., means glass-stoppered vial, the price of which is 10 cents, more or less; c.v., corked vial, 6 cents, more or less; c.b., corked bottle, 12 cents, more or less; g.s.b., glass-stoppered bottle, 18 cents, more or less. The cost of the bottles and vials as given is to be added to the price of the articles in all cases. In remitting cash for goods, remember to include price of package as per list below.

Familiar Science.

ADULTERATIONS OF FOOD AND MEDICINES.

As often as once in five or six years there is a general "awakening" upon the subject of the gross frauds practised in food, medicines, etc., and the newspapers and medical journals are filled with "exposures" and denunciations which frighten everybody but those engaged in the business of sophisticating and vending these substances. We are just now recovering from a popular spasm of this character, and hence may expect a season of "quiet" for the next few years. Unless consumers awake to a sense of their duty, the lard manufacturers will go on mixing water and alkalies with our lard; the grocers will sand our sugar; the spice-grinders will mix turmeric, logwood, and "fine feed" with our ginger, pepper, and allspice; our vinegar will be manufactured from oil of vitriol; and our "cream of tartar" will be found innocent of a single trace of true bi-tartrate of potassa. In medicine, the same mixing, extending, coloring, or exhausting processes will go on as heretofore, only, as new methods of fraud are developed, the sophistications will be more general and more cunning in their nature. Rhubarb, opium, and many of the valuable gums will be exhausted of their active medicinal principles before being offered for sale, or made up wholly from extraneous bodies. The "solid extracts" will continue to be manufactured from "soot and molasses"; and "salts" from sulphate of soda, chloride of sodium and gypsum.

It is difficult to decide which is the most reprehensible, the falsification and poisoning of foods, or the rendering inert and dangerous medicinal substances. If illness results from the bad character of foods and drinks, the remedies are rendered powerless to restore or eliminate poisons, and thus our condition is helpless indeed. At a future time we shall have some remarks to make regarding adulteration in medicinal substances. As regards foods, or condiments used in connection with them, we have to say, that adulterations will in a large measure cease when consumers *earnestly and determinedly demand pure articles.* A large proportion of the purchasers of groceries for family use never inquire of the dealer regarding the *purity* of the articles supplied. In cities, most families consume what dealers are pleased to furnish, asking no questions, or manifesting no anxiety as to quality. In the country, the matter of *cheapness* exerts a preponderating influence with the purchaser. If an article is only *cheap*, it meets with a ready sale, and thus the dealer finds his account in vending miserable, adulterated, cheap merchandise. If every housekeeper would *demand* of his grocer pure spices, sugars, cream of tartar, flour, lard, butter, etc., etc., he would fare much better than he now does, especially if the demand were intelligently and *persistently* made. Large dealers and small ones, almost always *know* regarding the purity of their articles. The impure are usually purchased with the understanding that they are impure. Wholesale grocers often carry on the business of mixing and adulterating in connection with vending, and they make no secret of it with their customers. There are, however, adulterators by profession, who do a large business with dealers, supplying them with the grossest and most attenuated mixtures at low prices. It is *competition* in trade which primarily causes much of the wretched adulterating business carried on; and the fires of this competition are fed by *consumers*, who bestow their patronage upon those dealers who sell the cheapest, apparently not caring for the matter of quality. Let every consumer say to his grocer, "Sir, I wish to be supplied with pure articles. I shall watch you closely, and, if you deceive me, I shall not only withdraw my patronage, but advertise you among my friends. I am willing to pay a fair price for everything I need, but never bring to my house a factitious article." This would be an emphatic admonition quite likely to be heeded by the small dealers, and it would immediately react upon wholesale dealers, and then again upon the professional adulterators. *Demand* pure articles, *insist* upon having them, and the effect will be most salutary. We do not submit these observations as indicating a perfect cure for the evil complained of, but the course recommended will aid greatly in mitigating it. Legislative enactments can never bring about a reform; at least, it is safe to say that, thus far, they have utterly failed, both in this country and in Europe. The "scoldings" and "exposures" of the scientific and popular press have proved equally futile; and hence it is clear, if the evil is ever in any degree abated, it must be by the action of consumers themselves.

HOW TO TAKE CARE OF THE SICK.

(CONTINUED.)

THE FOOD THEY REQUIRE.

Florence Nightingale says on this subject that one of the most common errors among women in charge of the sick respecting sick diet is the belief that beef-tea is the most *nutritive* of all articles. "Now, just try," she says, "and boil down a pound of beef into beef-tea, evaporate the water, and see what is left of your beef. You will find that there is barely a teaspoonful of solid nourishment to half a pint of water in beef-tea." There is, nevertheless, a certain nutritive value in it, as there is in tea; we do not know what. It may safely be given in almost any inflammatory disease, but it should never be alone depended upon, especially where much nourishment is needed. Again, it is an ever-ready saying, "that an egg is equivalent to a pound of meat," whereas it is not so at all. Much trouble has occurred from this mistaken notion. *It is a question whether, weight for weight, eggs are equal to beefsteak.* Also, it is seldom noticed with how many patients, particularly of nervous or bilious temperament, eggs disagree. Most puddings made with eggs are distasteful to them in consequence. An egg whipped up with wine is often the only form in which they can take this kind of nourishment. Again, if the patient is able to eat meat, it is supposed that to give him meat is the only thing needful for his recovery; whereas, scorbutic (scurvy) sores have been actually known to appear among sick persons living in the midst

of plenty, which could be traced to no other source than this, viz, that the nurse, depending on meat *alone*, had allowed the patient to be without vegetables for a considerable time, these latter being so badly cooked that he always left them untouched. To all intents and purposes he really had no fresh vegetables at all.

Milk and the preparations from milk are most important articles of food for the sick. Butter is the lightest kind of animal fat, and, though it wants the sugar and some of the other elements which exist in milk, yet it is most valuable both in itself as fat, and in enabling the patient to eat more bread. The reason of it is just this. Animals require in their food an albuminous constituent, a starchy one, and another of fat. The first, or albuminous (the purest form of which is the white of an egg), enters largely into the formation of the human body, the muscles being chiefly composed of it. The second, or starchy component, does not enter into the structure of the body as such, but is converted into sugar during digestion, and has much to do with the formation of the tissues and heat. The oily parts enter largely into the composition of the brain, nerves, and in fact all other portions of the body, and, when broken up and consumed, supply a good portion of the fuel for heat of the body. Besides these three mentioned, which are most conspicuous, there are other substances, as common salt, phosphates, iron, etc. These are supplied through food, but our space will not permit more than a mere reference. All food *must* contain these substances in proportionate quantities. If it does not, the appetite *craves* the one wanted, and, if not properly supplied, the part of the body suffers into which the wanting component enters.

To feel assured of this, if the reader thinks a moment, he will remember that no one likes bread alone, but wants some butter with it which supplies the oily part, and the appetite craves, too, a piece of meat, cheese or an egg, — the albuminous part. We want butter with our rice or potatoes, because rice or potato is almost pure starch, and wanting in fatty matter; so nature says we must *add* the wanting parts.

As all food which properly sustains man must contain these principles, it will be readily seen that those vegetable substances which are composed of but one of them, or even two, cannot *alone* support life. Experience confirms this view. Oils or fat are useful as oils or fat, but cannot supply the place of starch or sugar; nor can starch or sugar supply the place of albumen or flesh.

To obtain all these needful constituents, we must seek a *variety* in our food, and not depend exclusively upon any single one for continued use. There are some apparent exceptions to this rule, as in the case of milk, which we know is capable, under certain circumstances, of sustaining life for a length of time; but the exception is only apparent when we examine into the matter.

Milk has these necessary articles in suitable proportion, more than any other food perhaps in general use. It has the starchy part advanced a step into the shape of sugar, the albuminous part as the cheesy constituent, and the fatty as the creamy element. Hence, milk might be taken as a sort of representative diet, and better adapted to sustain the body in health, or to strengthen it in sickness, than any single article of food.

Flour made from wheat, meal from oats or Indian corn, grits, etc., come next in order perhaps, and stand at the head of the list of all articles of food grown for general consumption. Food of the above description is made up chiefly of starch, some albumen (under the form of gluten) and a certain amount of oil. Hence, bread made of flour, may well be called the "staff of life," because, from containing these elements, it is capable of supporting life by itself for a longer time than any other single article of food, excepting milk, as mentioned above. But, though containing these essential elements of life, yet flour, without the addition of albuminous or oily matter to a certain degree, cannot long *properly* sustain the human body.

If flour cannot nourish the body in a proper manner, it will at once be seen that corn-starch, arrow-root, tapioca and the like, which are nothing but pure forms of starch, made by washing away the oily and glutinous (albuminous) parts, cannot *possibly* be expected, when used alone, to afford more than a *limited* amount of nourishment; not of course as much as food prepared from flour which has *in* it the deficient articles. Not only is flour more nutritive than arrow-root, or any preparation of starch, but it is less liable to ferment, and as a rule it should be preferred whenever it can be used.

Do not misunderstand what is meant. None of these articles, compared with flour, are spoken of as *useless* to the body, but some preparations for the sick must be more useful than others, because they contain *more* of the elements of usefulness, in the shape of albumen, starch, oil, etc.

From what has been previously said, it will be seen that milk, when it agrees with the digestion, may be one of the most valuable articles we have to restore the sick, and, in many long chronic diseases, cream will be found superior even to milk, because of its richness in those parts the system most requires.

It seems to act in the same manner as beef-tea is generally understood to act, and to most it is much easier of digestion than milk. In fact, it seldom disagrees. Cheese is not usually digestible by the sick, but it is good nourishment for repairing waste; and physicians constantly see the sick desiring it, which craving shows how much it is needed by them.

But, if fresh milk is so valuable a food for the sick, the least change or sourness in it makes it of all articles, perhaps, the most injurious; diarrhœa is a common result of fresh milk allowed to become at all sour. The nurse therefore ought to exercise the utmost care in this. Yet, if you consider that the only drop of real nourishment in your patient's tea is the drop of milk, and how much almost all patients depend upon their tea, you will see the great importance of not depriving your patient of this drop of milk. Buttermilk, a totally different thing, is often very useful, especially in fevers.

In laying down rules of diet, by the amounts of "solid nutriment" in different kinds of food, it is constantly lost sight of what the patient requires to repair his waste, what he can take and what he cannot. You cannot diet a patient from a book; you cannot make up the human body as you would make up a prescription, and say so many parts "carboniferous," and so many parts "nitrogenous," will constitute a perfect diet for the patient. The nurse's observation here will materially assist the doctor; the patient's "fancies" will materially assist the nurse. For instance, sugar is one of the most nutritive of all articles, and is particularly recommended in some books. But the vast majority of all patients, young and old, male and female, rich and poor, hospital and private, dislike sweet things. A person may take to sweets when he is ill who dislikes them when he is well; and many fond of them when in health will in sickness leave off everything sweet, even to sugar in tea. Sweet puddings, sweet drinks, are their aversion. The furred tongue almost always likes what is sharp or pungent. Scorbutic (scurvy) patients are an exception; they often crave for sweetmeats and jams.

The desire shown by the sick, and especially by those who are getting well, for acid fruits, as baked apples, cranberries, lemons, etc., should never be disregarded. The important use the acids of fruits play in the body is a long story: so we can only insist upon the importance of regarding these "cravings" wherever found. Sometimes the physician has good reasons for not wishing them given, but as a rule these fruits, properly prepared, may not only be given without injury, but with decided benefit. So, whenever a sick person "craves" such things, be sure to call the physician's attention to it, and ask if you can give them.

Calves-foot jelly is another article of diet in great favor with nurses and friends of the sick. Even if it could be eaten solid, it would not nourish. It is simply the height of folly to take ¼ oz. of gelatine, make it into a certain bulk by dissolving it in water and then to give it to the sick, as if the mere *bulk* represented *nourishment*. It is now known that jelly does not nourish, that it has a tendency to produce diarrhœa, and to trust to it to repair the waste of a diseased constitution is simply to starve the sick under the guise of feeding them. If 100 spoonfuls of jelly were given in the course of the day, you would have given one spoonful of gelatine, which spoonful has scarcely any nutritive power whatever.

And, nevertheless, gelatine contains a large quantity of nitrogen, which is one of the most important elements in nutrition. On the other hand, beef-tea may be chosen as an illustration of great nutritive power, co-existing with a very small amount of solid nitrogenous matter.

Dr. Christison says that "every one will be struck with the readiness with which certain classes of patients will often take diluted meat-juice or beef-tea repeatedly when they refuse all other kinds of food." This is particularly remarkable in "cases of gastric fever in which," he says, "little or nothing else besides beef-tea or diluted meat-juice" has been taken for weeks or even months, "and yet a pint of beef-tea contains scarcely ¼ oz. of anything but water." The result is so striking that he asks what is its mode of action. "Not simply nutrient — ¼ oz. of the most nutritive material cannot nearly replace the daily wear and tear of the tissues in any circumstances. Possibly," he says, "it belongs to a new denomination of remedies."

It has been observed that a small quantity of beef-tea, *added* to other articles of nutrition, *augments* their power out of all proportion to the additional amount of solid matter.

The reason why jelly should be innutritious and beef-tea nutritious to the sick, is a secret yet undiscovered, but it clearly shows that careful *observation* of the sick is the only clew to the best dietary.

Chemistry has as yet afforded little insight into the dieting of the sick. All that chemistry can tell us is the amount of "carboniferous" or "nitrogenous" elements discoverable in different dietetic articles. In the great majority of cases, the stomach of the patient is guided by other principles of selection than merely the amount of carbon or nitrogen in the diet. No doubt in this, as in other things, Nature has very definite rules for her guidance, but these rules can only be ascertained by the most careful observation at the bedside.

Again, the nutritive power of milk and of the preparations from milk is very much undervalued; since there is nearly as much nourishment in half a pint of milk as there is in a quarter of a pound of meat. But this is not the whole question, nor nearly the whole. The main question is what the patient's stomach can assimilate or *derive* nourishment from, and of this the patient's stomach is the sole judge. Chemistry cannot tell this. The patient's stomach must be its own chemist. The diet which will keep the well man healthy may kill the sick one. The same beef which is the most nutritive of all meats, and which nourishes the healthy man, is the least nourishing of all food to the sick man, whose half dead stomach can *assimilate* no part of it, — that is, make no food out of it. On a diet of beef-tea healthy men, on the other hand, speedily lose their strength.

Patients have been known to live for many months without touching bread, because the *kind* they wanted could not be had, and they could not eat baker's bread. These were mostly country patients, but not all. Home-made bread or brown bread is a most important article of diet for many patients. The use of aperients may be entirely superseded by it. Oat cake and bread made of Indian meal are others.

To watch for the opinions, then, which the patient's *stomach* gives, rather than to read "analyses of foods," is the business of all those who have to settle what the patient is to eat, — perhaps the most important thing to be provided for him after the air he is to breathe.

Now the medical man who sees the patient only once a day, or even only once or twice a week, cannot possibly tell this without the assistance of the patient himself, or of those who are in constant observation of the patient. The utmost the medical man can tell is whether the patient is weaker or stronger at this visit than he was at the last visit. The most important office of the nurse, after she has taken care of the patient's air, is to take care to observe the *effect* of his food, and report it to the medical attendant.

(*To be continued.*)

THE GARDEN OF PLANTS.

One of the most wonderful and interesting places to visit in Europe is the celebrated "Garden of Plants," near or within the French capital. It is not only a garden of "plants," but a "garden" where all the sciences are cultivated, and where the student may study the different departments of science under the most favorable

rcumstances. A correspondent of the Boston *Herald* ıs presented some facts concerning the garden which ·e interesting:

"The cultivation of the plants has naturally occupied ıe most minute attention of its professors here. The ctures on cultivation and botany, free to all, are well ttended by foreign and French agriculturists, and the ırden, in return, receives daily from every portion of ıe world some returns in bread from the seed sown so berally from its pulpits. Vespasian Robin and the rothers Thouin brought the first contributions to its ower-beds, and Professor Decaisne to-day succeeds and olds up worthily the mantle of his great predecessor, I. de Mirbel.

"In chemistry and physics, ever since the foundation, he garden has been celebrated for the works of Lemery, Rouelle, Vauquelin, and Dumas, of former times, succeeded by two whose names are known throughout the world—Professors Chevreul and Fremy. In the earlier ays, when the garden was established for the pharmaceutical wants of the age, Lemery discoursed most wisely and eloquently upon the medical plants. He was most reserved and retiring in his manners. Rouelle, however, was of a peculiar nature; his arrival in the lecture-room was a signal for the profoundest stillness; as Professor, he was dressed in the perfection of the day, with wig and ruffles. On his arrival, his three-cornered hat alone was placed on a cushion, and his lecture began. As he warmed up with the subject-matter before him, he took off his great curled wig, unbuttoned and took off his embroidered jacket, then his waistcoat and his white cravat, and then in this attitude of being ready for the arena of intellectual combats, he, warming up still more with his great work, delivered some of his most thrilling scientific orations, and enchanted his hearers with every word he uttered.

"The collection of fruit-trees is most remarkable, and a monumental work is now in course of publication, entitled *Le Jardin Fruitier du Museum*, in which all the species of this precious collection, so useful for horticultural history, are noted and described. There are nine hundred varieties of pears alone. Sweet-water plants, in contradistinction to sea-water plants, here find a special attention.

"In the central flower-beds (of perennial plants) it will be noticed, above all if we visit it in the present month, that the colors of the flowers have a most unwonted brilliancy. This is not real, but only the effect of the disposition of the plants, by design, after the laws of contrast in colors, discovered by M. Chevreul. Every flower is as much indebted to its neighbor, perhaps more so, than to its own petals for its brilliancy of color. Separated, they lose that marvellous coloring which they give back to us when we look upon them together. Near these beautiful beds is the first acacia planted in France, in 1787, by Vespasian Robin. Buffon died in the building now used as the *intendance*. The portion reserved to the botanical students, to which any can enter with a ticket which they have to seek for at the direction of the administration, is very vast (some six acres) and divided up into little squares of about a yard. In each you will see the iron label which gives you the name of the plant, and when they ripen, the seeds are carefully gathered and distributed throughout the country, as the quality is supposed to be the best and the species most desirable to propagate. All the poisonous plants, like belladonna, are in the same little squares, but covered over with an iron cage so they cannot be reached.

"Near to these little plots is the collection of animals. The birds are very beautiful, and the parrots and cockatoos, of the largest specimens, are in summer taken out from their warm rooms and in the open air on the lawns. The birds of prey, *carnassiers*, are very large and fine—eagles, condors, vultures and hawks—some with a spread of six feet wings, are fed by the public, who gape at them in wonder.

"The babies and the nurses are most pleased with the monkeys. The collection is large and fine. They have their palace, which will easily hold a couple of hundred, and, although not nearly so costly or so extensive as the more modern one of the Zoological Gardens in London, yet it caused many reproaches to be made to M. Thiers when, as minister, he committed the audacious extravagance of building this monkeys' cage.

"The elephants, dromedaries, giraffes, rhinoceroses and hippopotami are by themselves. All of them have reproduced here except the rhinoceros; the hippopotamus no less than four times, and each time the mother has killed her young shortly after being born. Philosophers have thought it was a moral reflection of the *maternal* that she would prefer to see her children dead rather than be turned out into the temptations of this gay capital. No other reason has ever yet been assigned for the dislike of the hippopotamus to the Parisians. Of one thing it is certain, the dislike is quite mutual. The cages of the wild animals have served as the model for most of the gardens in Europe, but are now too small. The lions have a small park in which they can go out and be in the rain and cold which they sometimes find with the snows in Asia and Africa on the mountains. The bear gardens are very deep fosses, lined with stone walls, and so built as to prevent Bruin from climbing anything but the old stump in the middle. They look the mildest of creatures, but it would not be safe to fall into their clutches.

"The reptiles have a small and the very oldest of the buildings to live in. Here are alligators, crocodiles, boas, chameleons, lizards, rattle-snakes and many others, which flourish very well. The salamander, from Japan, has been for years in the tub where he is kept. He grows and fattens, and evidently enjoys himself. One of the pythons swallowed, some years since, her woolen blanket entirely; but finding the food set heavily on her stomach, rendered it up again, and the blanket is kept as a curiosity to show to the visitors.

"It was here that Prof. Dumeril first noticed the reproduction of the *axolotl* before they had arrived at maturity, a thing quite unknown in any other animal with vertebræ. They flourish here remarkably well and are raised by hundreds.

"One of the greenhouses is appropriated to the plants of New Zealand, New Holland and the highlands of Mexico. In the one farthest westward, which is always kept heated, the tropical plants are in the greatest luxuriance. Here is the bamboo, the elephants' grass, and the canepole. One of the plants here, the leaves of which are no less than thirty feet long, has several times pierced the outside glass. To avoid the annual repairing of the greenhouses, the top leaves of this plant, the *Arengha*, are always cut.

"In the Round and the Holland hot-houses are to be found the palms, the cocoa, and the *cycas*, which is a great rarity; plants from Central America and the West Indies, from Africa and the Cape, such as the *cycadees*—those plants whose leaves appear cut off from metal; *orchidees*, *pandances* and the *tornelia fragrans*, which is supported from a plateau, and winds its leaves in with its falling roots. Here is also a remarkable specimen of the *Victoria Regia*. But to mention all, or even the principal plants in these vast greenhouses, would require more than a volume. To give an idea of the importance of a plant properly bestowed, one fact connected with the Garden of Plants will suffice. In 1720, Antoine de Jussieu, Professor at the Garden, gave a coffee-plant to an ensign of a sloop of war going to the westward (M. Declieux), who carried it to Martinique. That single plant has produced all the coffee plants now known in the West Indies; just as from the single acacia, planted in this garden in 1637 by Vespasian Robin, were produced and grown all the plants of that species now so common throughout France and her colonies."

Arts.

PROFESSOR HENDRICKS ON FORCE.

Editor Boston Journal of Chemistry:

In response to Mr. O. P. Barton's remarks, in the current number of the *Journal*, upon my article on Force, I answer:

The difficulty Mr. B. points out is, to a certain extent, real, and presents itself in every case when an attempt is made to sound, to the extremest depths, any subject whatever. No question can be answered wherein the answer does not ultimately lead to a question that cannot be satisfactorily answered. This fact must necessarily be admitted, as a consequence of the essential *relation* of phenomena, when we consider that the extent of the horizon of the human intellect is as nothing when compared with the boundless expanse beyond.

In the article alluded to I have taken the liberty to extend my argument, by inference, outside the boundary of actual knowledge, and therefore do not pretend that I shall be able to answer questions that immediately suggest themselves.

Many of the phenomena and laws of light and heat may fairly be regarded as at present lying *within* the boundary of human knowledge. But their discussion and comprehension are greatly facilitated by the assumption that a luminiferous ether, such as is indicated in the article alluded to, is everywhere present throughout unlimited space. In my article I have assumed this as an admitted fact, and have attempted to show the connection between this and some other universally recognized facts.

The *nebular hypothesis*, which in its main features receives additional support from every new discovery in astronomical science, assumes that the solar system, and by analogy every other system of the universe, once existed in an ethereal or *nebulous* condition, occupying at least all the space included within the orbit of the remotest planet, and that, from *some* cause, which is called *gravity*, its parts have been isolated and consolidated into their present condition. Now this hypothesis, of which I do not hesitate to count myself a believer, has failed to explain the *operation* of gravity, to account for the *commencement* of the consolidation of nebulæ.

In the article criticised by Mr. B., in addition to the assumptions of the nebular hypothesis, I have suggested that *possibly* the ultimate state of a nebula, before its condensation commences, is that of the ether itself. And, as in that case we have no gravity to effect the condensation, I have tried to show that condensation, when once initiated, would result from the vibrations of the ether itself. I confess I have not obviated the difficulty of accounting for the initiation of the phenomena, but I claim that my view of the case presents a *conceivable* method of dispensing with gravity as a *property* of matter, which, to my mind, *improves* the nebular hypothesis.

We have no knowledge of, nor can we conceive as possible, matter in a state of absolute rest. I assume then, not only that matter always *was*, but that it always was in *motion*, and that every form of force is simply the manifestation of a transfer of motion from one portion of matter to another.

If all the motions of the universe were consonant, as would be the case if the universe were homogeneous, the motion could by no means be recognized. Heterogeneity is therefore essential to a recognizable world. The simplest conception that I can form of a recognizable world is, therefore, an infinitely extended ether, in motion, having nucleated centres.

The foregoing is submitted as an apology for, and an elucidation of, my article on Force. I will now endeavor to answer more directly the inquiry of Mr. Barton.

Mr. B. asks, "How is it possible for a constant force, applied to an inert mass, to impart more power than itself possesses, so that it shall react upon itself."

I answer, that the absorption of force or motion from, or its radiation to, an unlimited medium, as the ether is supposed to be, by a limited mass, as a nebula, would not sensibly increase or diminish the amount of motion in the medium, although the change in the nebula might be very great.

It is demonstrable from the laws of light that the ethereal wave is retarded while passing through a refracting

medium, such as a nebula may be supposed to be; the matter of the nebula must therefore receive a corresponding impulse in the direction of the wave. As the ethereal waves will act similarly upon all parts of the surface of a nebula, it is easy to see that they must effect its condensation to a certain extent. Let it be granted that gravitation is the result of such an absorption of ethereal waves, by a nebula, it follows then, from the nebular hypothesis, that condensation and axial rotation result from ethereal vibration. But a stage of condensation must ultimately be reached — as has been by the planets at least of our solar system — when the same amount of force would fail to produce further condensation, and the augmentation of heat, or molecular motion, resulting from condensation, will then also cease. Now, granting that, in the changed condition of the system which has resulted from its condensation, it continues to absorb the same amount of motion from the ether that it did in a less condensed state, yet, as its molecular motion, or heat, has been greatly augmented during its condensation, it will now radiate to the ether much more motion than formerly, so that the sum of its forces will be diminished by radiation.

That this stage of development, or rather of decay, of every part of the system, including the central mass, or sun, must ultimately be reached, is sufficiently obvious: for of the two conditions, both of which are *essential* to the stability of the system, we have probably neither, and *certainly* not both; that is, though we are not *sure* that the worlds move in resisting media, we *are* sure that they are not solid bodies. The doom of the system, as such, is therefore written upon it, and may be read even now, though the *period* of its growth and decay may surpass even the imagination. The whole process, however, constituting the growth and decay of a system, is but a cycle in the changes of matter, and will forever be repeated under an *infinite* variety of forms.

J. E. Hendricks.

Des Moines, Iowa, July 14, 1869.

POWER OF THE OCEAN TIDES.

"It is said there is power enough in the rise and fall of the tides to drive all the machinery that man would ever have occasion to use." This paragraph, from one of the April numbers of the *Journal of Mining*, is a most suggestive one, considered from a mechanical and utilitarian point of view. That the statement is correct, we propose to show by a rough estimate.

In many parts of the sea-shore the rise and fall of the tides is considerable. In the Bay of Fundy, 70 feet; at the mouth of the Severn and at St. Malo, France, 46 feet; at Guernsey and Jersey, 32 to 38 feet; at the mouth of the Scheld, 20 feet, and along the coast of Holland, from 10 to 16 feet; in the Adriatic only 2½ feet; while in the rest of the Mediterranean the tides are scarcely perceptible; along the east coast of the United States the tides vary from 4 feet to 10 and 20.

As the original tide-wave is generated in the Pacific Ocean, and moves westward with the apparent motion of sun and moon, it is clear that gulfs having their mouths funnel-shaped, and opposed to the direction of the tide-wave, like the Red Sea, will have a strong tide. As the tide-wave moves from the Pacific Ocean around the Cape of Good Hope, and then northward in the Atlantic Ocean, the same peculiarities are observed — any gulf having its mouth toward the south, and funnel-shaped, like the Bay of Fundy, will have a strong tide, and where the mouth is narrow, like that of Chesapeake Bay, the tide-wave will be less high than in the free ocean. When the tide-wave reaches any place on the coast from two sides, as is often the case behind large islands, the effect will be to increase or diminish its height, according as the high tides coincide, or the high and low tides neutralize one another.

We have no space to apply these rules to the numerous special localities, from observations of which they have been deduced; but they serve to show that the subject has been thoroughly investigated, and is as well understood as any other in physical geography. The power exerted by the tides every day, along thousands of miles of sea-coast, is especially remarkable, as it is the only natural force directly dependent on gravitation, which owes nothing to the heat of the sun, itself a result of gravitation, and in its turn the cause of all other forces on the surface of our planet, either wind or water-power, steam-power, or the power of animals.

To estimate the force of the tides, all that is necessary is the consideration that the attraction of the sun and moon (principally of the latter), acting in opposition to terrestrial gravitation, elevates the surface of a large portion of the ocean, nearly twice in twenty-four hours, to the mean height of about two feet. The extent of surface thus raised may be set down at 100,000,000 square miles, or one half of the surface of the earth, taking this at 200,000,000 of square miles, of which the ocean occupies about three-fourths, or 150,000,000. Every square mile of water two feet thick contains nearly 60,000.000 cubic feet, or 3,840,000,000 pounds of water, and this, multiplied by 100,000,000, the number of square miles affected by the tide, gives the enormous number of 768,000,000,000,000,000 foot pounds exerted every 12½ hours, or 750 minutes, which gives, per minute, a power of 100,000,000,000,000,000 foot pounds. Dividing this by 33,000, to reduce it to horse-power, we obtain nearly 3,000,000,000,000 horse-power as the total power of the tide-wave over the whole surface of the earth.

Only a small portion of this power, however, can be made available — namely, that which is spent on the sea-coasts of continents and islands. The method of utilizing this we will discuss in a future article. — *Engineering and Mining Journal.*

OXYHYDROGEN ILLUMINATION.

L'Abbe Moigno. — This paper is written with the express view of meeting the objections made in public prints against this mode of procuring artificial light, and answers each objection, completely. The first objection, made and refuted, concerns the alleged difficulty which oxygen is supposed to have of passing readily through pipes, and travelling therein with ease, on account of its high specific gravity; the author states that experience has proved that, under the same, and, in all respects, identical conditions, oxygen gas travels more rapidly than hydrogen. Another point is an objection concerning the comparatively rare occurrence of peroxide of manganese, and the difficulty of obtaining it; to this the reply is, there is plenty of manganese, of excellent quality, readily accessible, and more than fifty times as much as any greatly-increased demand will ever absorb; moreover, the oxygen is made from permanganate of soda, which, it appears, is revived again after having yielded its oxygen. One ton of this permanganate yields in twenty-four hours 100 cubic metres of oxygen; and, from reliable data obtained, 300 tons of the salt will suffice to produce yearly about 10,000,000 cubic metres of oxygen gas (a cubic metre is equal to 35.316 cubic feet). These 300 tons of permanganate are composed of 150 tons of soda, and 150 tons of peroxide of manganese, an insignificantly small quantity, compared with the 60,000 tons which are consumed of this material annually. As to the too slow production of oxygen, the author says, at the oxygen gas-works, when in regular course of working, they have obtained, from each retort, 38 cubic metres of pure gas per day; as to the cost, he states that the gas-work intended to be established will cost, everything included (retorts, &c., gas-holders to hold 24,000 cubic metres of gas for twenty-four hours supply, 32 kilometres' length of mains), 3,700,000 francs; as to the objection concerning the zirconia, or magnesia cones, these last for several days, and only cost one centime; at the same time, the glass chimneys and globes are dispensed with. As to the expense of this gas, it appears, from the statements of the author, that, taking into consideration the great quantity of light obtained, it is decidedly less expensive. The manufacture of hydrogen, by means of the patented process, from hydrate of lime, is, according to the author, very simple, and the pure hydrogen thus obtained costs less than two centimes per cubic metre, leaving even out of the question the sale of the by-products, which would not be trifling. Lastly, the author tells us that MM. J. Dumas (Senateur, etc.), Jamin, Balard, and H. Sainte-Claire Deville, all Members of the Institut; M. Debray, of the French Imperial Mint; and M. Alphand, Director of Public Roads and Promenades, have been appointed a committee, by M. Haussmann, Préfet du Département de la Seine, to inquire into, and minutely report upon, this subject in all its aspects and details. — *Chem. News.*

Keeping Volatile Liquids. — Chemists and others know well the difficulty of keeping very volatile liquids. Bottles of ether, for example, are shipped for India, and when they arrive are found to be more than half empty. The chemist sometimes puts a bottle of benzole or bisulphide of carbon on his shelves, and when he next requires it, he finds the bottle empty and dry. The remedy with exporters is a luting of melted sulphur, which is difficult to apply and hard to remove. A new cement, therefore, which is easily prepared and applied, and which is said to prevent the escape of the most volatile liquids, will be useful information to many. It is composed simply of very finely ground litharge and concentrated glycerin, and is merely painted around the cork or stopper. It quickly dries, and becomes extremely hard, but can be easily scraped off with a knife when it is necessary to open the bottle. — *Medical and Surgical Reporter.*

A new and elegant method of preparing nitrogen gas has been made known by a distinguished Italian chemist, Signor Massimo Levi. It consists in heating bichromote of ammonia in a retort; the salt is thus resolved into green oxide of chromium, water, and nitrogen gas.

STATISTICS OF PHOTOGRAPHY.

The rapid growth of new and special industries, says the *British Quarterly Review*, is a fact so characteristic of the present day, that the statistics of photography can scarcely be regarded as wonderful, viewed merely as a question of economics. Nevertheless, some of the facts are sufficiently startling. Twenty years ago, one person claimed the sole right to practise photography professionally in England. According to the census of 1861, the number of persons who entered their names as photographers was 2,534. There is reason, however, to believe that these figures fall short of the real number; since then it is probable the number has been doubled or trebled, and that including those collaterally associated with the art, it is even four or five times that number. But these figures fall far short of the number interested in photography as amateurs. We are informed that eight years ago, in establishing a periodical which has since become the leading photographic journal, a large publishing firm sent out twenty-five thousand circulars — not sown broadcast, but specially addressed to persons known to be interested in the new art-science. The number of professional photographers in the United States is said to be over twenty thousand, and a proportionate number may with propriety be estimated as spread over continental Europe and other parts of the civilized globe.

But a more curious estimate of the ramifications of this industry may be formed by a glance at the consumption of some of the materials employed. A single firm in London consumes, on an average, the whites of two thousand eggs daily in the manufacture of albumenized paper for photographic printing, amounting to six hundred thousand annually. As it may be fairly assumed that this is but a tenth of the total amount consumed in this country, we obtain an average of six millions of inchoate fowls sacrificed annually in this new workshop of the sun in the United Kingdom alone. When to this is added the far larger consumption of Europe and America, which we do not attempt to put in figures, the imagination is startled by the enormous total inevitably presented for its realization.

The French Atlantic Cable. — This cable, now successfully laid, has some modifications of construction. The gutta-percha employed for insulation is brought direct from Singapore, as it left the hands of the natives, in the shape of unsightly idols, deformed quadrupeds, caricatures of patriarchs, dogs, ships, birds; and is made into a paste for protecting the electric core. The copper wire is received from the wire-mills in hanks of fifteen or twenty pounds each; each hank being tested on its arrival to ascertain its conductivity, none below a certain standard being allowed to be used. The conductor consists of a strand of seven wires, 0.56 inch in diameter, or a little less than one-sixteenth of an inch, six being twisted round the central wire. The seven wires are rendered perfectly compact by the coating of the central wire with an adhesive matter known as "Chatterton's Compound." The weight of the complete strand is four hundred pounds per nautical mile. It is made in lengths of about one mile, and wound on reels ready to be covered with gutta-percha. The strand is passed through a vessel of Chatterton's Compound, and through a die corresponding to the size of the first coating of gutta-percha, which is forced round the strand as it passes through the die. Four successive coats are thus applied, and between each coating the wire receives a film of the compound, which improves the insulation and binds the coats together. The total weight of the core is 800 lbs. per nautical mile, equally divided between the copper and the gutta-percha. The total length of cable for the section between Brest and St. Pierre is 2,788 nautical miles, the second section thence to New York 776 nautical miles long, with smaller wire consisting of a conductor of 107 lbs. per nautical mile, and a covering 150 lbs. per mile. The cable thus prepared is finished with a serving of jute yarn and ten wires of homogeneous iron, each of which is covered with manilla yarn steeped in tar. — *Engineering Journal.*

Improved Mode of Manufacturing Glucose from Starch. — M. Maubré. — The author states that, by the usual mode of proceeding, a portion of the starch is always left in the state of dextrine; he therefore operates under pressure and a higher temperature. For this purpose, he applies a strong cylindrically-shaped iron vessel, internally lined with lead; this boiler is charged with 28 kilos. of sulphuric acid, at 60° Beaumé, and 2800 litres of water, and this liquid is brought to the boiling point by means of high pressure steam. When boiling, there is gradually run into this fluid a mixture of 1180 kilos. of starch and 2500 litres of water, acidulated with 28 kilos. of sulphuric acid. When the whole of this quantity has been introduced into the aforesaid boiler, it is closed, and the temperature within it raised to 160°, by means of high pressure steam introduced into the boiler by leaden and perforated pipes. After about four hours, the action is complete, the fluid run off into tubs, and the acid saturated by means of 84 kilos. of finely-powdered good limestone. After separation of the sulphate of lime, the fluid is evaporated to 20° B., clarified with animal charcoal, and next evaporated in vacuum pans, yielding an excellent and beautiful glucose. — *Les Mondes.*

Acid Proof Cement.—The best preservative for corks exposed to acids consists of a coating of silicate of soda and powdered glass. The cork, having been bored to suit the size of the tube, is soaked for two or three hours in a solution of silicate of soda, consisting of one part of commercial concentrated solution to three parts of water. The tube is next inserted, and, when dry, the cork is covered with a paste made by mixing the condensed solution of the silicate with powdered glass in such proportion as to form a mass of about the same consistence as that of putty. This is spread on the undersurface, and then washed with a solution of chloride of calcium. It soon hardens, but it is advisable to make the connection with the flask while the paste is in a plastic state, and to allow it to become solid before applying heat to the vessel containing the acid.

Corks protected in this manner are but slightly acted upon, though remaining over the boiling nitric acid more than four hours, and over hot acid for ten. In some instances, when not entirely covered, the vapor softens the cork beneath the silicate to the depth of about a quarter of an inch, but the cement has proved sufficiently strong to form a compact diaphragm, enabling the tube to be removed from the flask without danger of the fluid contained being contaminated. The application of this cement as a luting for chemical apparatus for general use is suggested, as it is found that it remains unaffected even when immersed in strong nitric, sulphuric, or muriatic acid. The immersion in these liquids, made while the plaster is still soft, has the only perceptible effect of hardening the same immediately.—*Journal F. Institute.*

Mineral Lemonade.—When equal parts by weight of strong pure sulphuric acid and strong pure alcohol (85 to 90 per cent) are carefully mixed (the acid being poured into the alcohol and thoroughly mixed therewith), a liquid is obtained which has long been known and used by medical men under the older name of *Elixir acidum halleri*, more recently named *Mixtura sulphurica acida.* This fluid, which, if well prepared, contains essentially sulphovinic acid, is an excellent summer beverage when mixed with water in the proportion of one small teaspoonful to a tumbler of cold water, and sweetened with sugar, or, preferably, with some fruit syrup. Above the lemonades made with vegetable acids this acid mixture has the advantage of not increasing the perspiration, as citric and other vegetable acids do, while it is better borne by the stomach, and has a tonic action upon the vascular system. It is, indeed, a very pleasant drink, often given, at the *cafés* of Paris, Berlin, Vienna, and other places, along with some *syrop de groiselles* or *framboises*, and rather exorbitantly charged for. The proportions by bulk are—one of strong sulphuric acid and three of alcohol.—*Hamm's Agronomische Zeitung.*

Cellulose in Old Wood.—M. Payen has taken the trouble to analyze a piece of old woodwork, once belonging to the well-known Chaillot pumps, in order to ascertain what state the cellulose was in, after fully a century's exposure to wind and weather; he therefore treated the wood—first, for eight consecutive days, with a weak solution of caustic potassa (1 part in 10 of water), at a temperature of between 20° and 75° C.; secondly, he treated the residue with nitric acid, sp. gr. 1.2, without applying heat, and also for eight days; next with nitric acid, sp. gr. 1.05, taking care to wash out carefully all substances which, by each of these operations, could have become soluble, previous to proceeding with another operation; M. Payen obtained pure cellulose, as might have been expected, and was evidently also expected by Field-Marshal Vaillant, who happened to be present when the *savant* deposited, at a meeting of the Agricultural Society, a piece of pure cellulose, obtained from the wood of the old pump, since the marshal asked Payen, jocosely, whether he had not some old wood from the ruins of Carthage to operate upon; and M. Robinet, improving upon the occasion, offered to send Payen a piece of the wood of Noah's Ark, to continue his researches.—*Chem. News.*

New Test for Blood-Stains.—Upon the authority of the London *Lancet*, an important test for blood had been discovered in Australia; consisting of the application of tincture of guaiacum and ozonized ether, which produces a beautiful blue tint with blood or blood-stains. The test is excessively delicate; and we happened to be present at a lecture given by Mr. Bloxam, in which he showed some experiments with it, and added that, in the case of a blood-stain twenty years old, he had extracted a single linen fibre with an almost inappreciable amount of stain on it. The characteristic blue color was immediately induced by the test, and readily detected by microscopical examination. The testimony of so able a chemist leaves no doubt as to the value of the discovery. Ozonized ether, we may remark, is merely a solution of peroxide of hydrogen in ether.

On Electricity.—"I believe that the true theory of electricity will result from the principle that electricity is not a motion (*mouvement*), but a change of the quantitative and dynamic equilibrium of the ether which constitutes the atoms of the substances, and that the propagation of such a change is brought about by the moving of the ether from one atom to another; this motion shakes, disturbs the ether of the atoms, and thus produces heat."—*Father Secchi.*

Agriculture.

LAKESIDE IN AUGUST.

The season at Lakeside Farm has so far advanced that we are able to know positively regarding the character of some crops, and the results of some experiments; and also we may reasonably prognosticate in respect to the results of nearly all the cereal grain and root crops which are as yet immature.

The wheat has been safely housed, and never was the grain more plump, or the straw more magnificent. This is the fourth consecutive season in which we have successfully grown this noble cereal, and we predict a larger yield per acre in the present crop than ever before. At the present time of writing, it has not been threshed and measured, but an estimate of thirty bushels to the acre is apparently a safe one. Neighbors and friends, acting under the stimulus of the example afforded them, ventured to adopt our method of fertilizing wheat grounds, and, last spring, sowed generous fields to wheat. We are happy to know that their success corresponds in a measure with our own. It is high time the erroneous idea was dissipated from the minds of Massachusetts farmers that they cannot grow this grain. We *can* and we *must* cultivate it. It is a most profitable and satisfactory crop. Nothing is more gratifying, nothing conveys stronger assurances of *independence*, than broad fields of this golden grain waving in the wind. Let us see more of them upon our New England farms.

The corn fields never looked better. Under the stimulus of our favorite fertilizer, made from a mixture of bone flour and ashes, the corn is growing in rank luxuriance, and the yield promises to be a heavy one. Doubtless there are more promising corn patches in the State, but we have thus far in our travels failed to find them. We have noticed, in one or more of our exchanges, statements that the bone and ash mixture recommended in the *Journal* has disappointed farmers, in some instances. We suppose there never was, and we venture to say there never will be, a fertilizer suggested that will not work badly with *some* cultivators. We shall have some observations to make upon this special topic before long.

Of apples, there are none. From an orchard of five hundred trees of bearing size, not a single barrel will be gathered. This is the sixth year since a full apple crop has been secured in New England. It is enough to discourage fruit-growers.

The vineyard is looking finely. The fruit is fully a fortnight in advance of the last season, and, if nothing untoward happens, as mildew or early frosts, the rich clusters will present a fine aspect in September.

The tubers as yet have escaped the disease which proved so disastrous the last season. Our crop, grown upon "virgin soil," a tract covered with a thick growth of oak and hickory last year, is not only a fine one in quantity, but of unusual excellence in quality. The Early Rose grew rapidly, and in the first week in July they had attained to nearly their full size, but they were not fit for the table. When boiled, the watery sodden lumps of starch were found wholly unpalatable, and were thrown to the pigs. As they ripen they grow better, but, as an early variety suited to early use, they have not met our expectations. We have raised them on different fields widely apart, and the results are the same.

The hay crop at Lakeside has proved, upon the whole, a fair one. The severe, open, icy winter destroyed many of the grass roots, and caused some unsightly bare patches to appear in the fields. The heaviest swarth was mowed upon the reclaimed meadow, upon a portion subdued and seeded down a year ago. The yield was quite three tons to the acre. Upon the experimental grass-plat of one acre, forty-two hundred and fifty pounds of excellent hay was secured. This is the *sixth crop* taken from the field, and no animal excrement or stable manure has been employed. It was brought into good tilth, and has been maintained solely by the use of chemical fertilizers. We shall publish a full statement of results on this and other fields at a future time. At present the men are busy at work upon the low lands, draining, removing the hassocks and bogs; and another year we hope to see excellent timothy growing in places where hitherto has been found nothing but wire grass and bulrushes.

AN ENGLISH FARM.

We have recently received a pleasant visit from William Lawson, Esq., proprietor of the celebrated Blennerhasset Farm, Cumberland, England. Mr. Lawson has been travelling through the United States for puposes of observation and pleasure since November, and, before leaving, will make the trip to California over the great Pacific Rail Road. He is much pleased with our country, and surprised at its extent and the vastness of our agricultural resources.

His farm in England consists of about four hundred acres, all of which is in the highest state of cultivation. He has sixty acres to potatoes, forty-five to wheat, thirty-three to Swede turnips, sixty-eight to oats, six to carrots, ten to barley, sixty to hay, five to Italian grass, four to cabbage, four to flax, twenty to garden, etc. He devotes, this year, *nine acres to experiments*, and has in his employ an experienced chemist, who has charge of all experimental labor. Fertilizers are manufactured in large quantities upon the premises, and Mr. L. is ready to supply his neighbors with what they may need at a small advance from cost. Formerly, a large number of animals were maintained upon the farm, but, regarding the production of grain and roots as more profitable, and wishing to try the experiment of maintaining the lands in good condition by chemical or special fertilizers, the stock was removed and a new system adopted. It has thus far proved successful, and we shall look with much interest to future reports of experimental results. The plowing, threshing, and nearly all other labor in which machinery can be employed, is done by steam power, and he finds it to greatly reduce the expense of cultivating the farm. The land is thoroughly underdrained, and the soil kept in the best possible condition by turning up, pulverizing, and weeding. Owing to the extreme drought in England the past season, many of his crops were greatly injured, and his experiments interfered with; but this year, his superintendent informs him, the crops are in a highly satisfactory condition.

The experiment which Mr. Lawson is trying upon a large scale at Blennerhasset farm, in dispensing with excrementitious manures, is almost precisely like the one which has engaged our attention during the past six years in a comparatively small way, at Lakeside farm, in Essex county. The difference, if there is any, may be presumed to consist in the dissimilar condition of the soil when the experiments began. In our case, the land was run down, or exhausted. Mr. Lawson's farm must have been left in good condition at the time of the sale of his stock. Our object has been to put exhausted lands into good tilth without manure; his aim is, to keep up the fertility of rich fields through similar agencies.

We claim that a successful end has been reached in our experiments, and, that fact being established, it certainly insures the success of Mr. L. in that in which he is engaged.

Our experiment has in a measure come to an end through its entire success, the farm, by the use of chemical fertilizers alone, having been brought into a state capable of sustaining a herd of animals: they have been supplied, and therefore the excrementitious manures furnished, in part meet our wants in maintaining a high degree of fertility.

Mr. Lawson employs bones, ashes, salts of ammonia, nitrate of soda, and potassa, chloride of sodium, lime, etc., and is pursuing a course, in compounding and chemically manipulating these substances, which shows much discrimination and scientific knowledge on the part of the chemist who has the work in charge.

Mr. L. is also trying another experiment this year, of a character unlike the one alluded to. He is working his farm upon the co-operative plan; that is, giving his employés an interest in the productive results of their labors. Two and a half per cent upon the capital employed, reckoning the farm at its market value, is reserved from the net profits for himself, and the remainder is divided upon an equitable plan among his laborers. The laborers are paid regular wages, which goes into expense account. The plan is working well, and satisfactory results are anticipated by employer and employés.

We regret that want of space compels us to refrain from giving a more extended account of the Blennerhasset Farm, and of the interesting experiments which are being carried on there. Upon Mr. L.'s return from California, he will spend a few weeks in looking over New England farms, and we hope to be able to introduce him to some of our prominent agriculturists.

THINNING OUT GRAPES.

Is the importance of thinning out the fruit of the vine duly considered by the majority of cultivators? I think not. From close observation, and even sad experience, the subject, in my opinion, calls for much more attention than is usually given. In young vines, this is particularly the case.

Such vigorous and hardy constituted varieties as the Concord may stand it, but even they will eventually suffer. This fault is not only to be found in the vineyards of the novice, but can be seen almost everywhere, in charge of those who know better. This then, being admitted, the next question is, How shall it be remedied? Shall we prune so much shorter, so as not to leave more wood than the vine can carry safely through or leave more wood, and then thin out the bunches?

The latter, in my opinion, will be the best; for, by the first plan, we get our fruit too much crowded, and throw too much force into the young canes for the following year's bearing. My impression is that when a vine is pruned to what would seem about right, the pinching out of every third bunch, at the first operation, pinching back would be the method. I would leave but two bunches on each bearing shoot, and in some instances it is better to leave but one.

We all know that the forming of the seed of any fruit is the heaviest tax on the plant. This being the case, do we not give considerable relief when we diminish this tax one-third? I think we would be safe in counting on having the same weight of fruit in the two bunches as if three are left. Some years ago, we grew Concord bunches in this way, which the committee, who were to test them, would not admit to be that variety until they tasted them. For marketing table grapes this is particularly practicable. For instance, let one man take Concords that will average three-fourths of a pound to the bunch, and another have them as usually grown, and my word for it, the large bunches will command nearly double price, not only among the wealthy, but the masses. — *Grape Culturist.*

Grape Vines about Rocks. — It is a well-established fact that grapes ripen very much earlier at the North when the vines are planted near or about rocks. Last year, while grapes were nearly a failure in the open field, there were cases where a fine crop of perfectly ripened bunches was raised from vines whose roots ran about rocks. The rocks absorb the heat by day, and keep the roots of the grapes warm day and night. Rocks in gardens and fields are generally regarded as nuisances; but if they are left, a good use can be made of them by planting vines about them. — *American Journal of Horticulture.*

How Much Manure do we Use on an Acre? — An acre of land contains 43,560 square feet, 4,840 square yards, or 160 square rods. By those who have used guano, it is said that 300 pounds is sufficient to manure an acre; 302¼ pounds would give 1¼ ounces avoirdupois to the square yard. One cubic yard would give a trifle over one cubic inch to the square foot. A cubic yard of highly concentrated manure, like night soil, would, if evenly and properly spread, manure an acre very well. A cubic yard of long manure weighs about 1,400 pounds; a cubic foot not far from 50 pounds. A cord contains 128 cubic feet; 1¼ cord would give about a cubic foot to the square rod. If liquid manure be used, it would take 180 barrels to give one gill to a square foot upon an acre, which would be equal to about 50 pipes or large hogsheads. It would be quite useful if farmers would be a little more specific as to the manure applied.

To Rejuvenate Old Grape Vines. — The editor of the *Practical Farmer* says: — "Having on our premises, planted by former owners, probably twenty years ago, half a dozen old grape-vines with large weather beaten trunks or stems, which made annually but little new wood and yielded but very few poor grapes; two seasons ago we cut off the branches, covering with about a foot of earth. Vigorous and healthy shoots sprung up in great abundance — the weak ones of which were broken off, and leading ones at proper distances trained to the arbor. The new growths are now clean, healthy, and strong — sufficient entirely to cover the large arbor the present season; we look for bushels of fruit from the new bearing wood. We see old grape vines, everywhere, doing no good, and which could be made young and thrifty by this process."

Boston Journal of Chemistry.

BOSTON, SEPTEMBER 1, 1869.

☞ Any person sending us the names of *three* new subscribers, with full pay enclosed, will be entitled to a *fourth copy of the* Journal *gratis*. For *five* new subscribers, we will send the *petite microscope*. For *eight*, we will send one set of Twenty Small Carpenters' Tools in a Hollow Handle— a most convenient article. For *ten*, we will send a copy of Dr. Nichols' book, "*Chemistry of the Farm and the Sea*," or Messrs. Rolfe and Gillet's "*Handbook of the Stars*," or the "*Handbook of Chemistry*," by the same authors. *These are all beautiful and instructive books.* For *twenty* subscribers, we will send the "*American Naturalist*," published by the Peabody Academy of Science, Salem, for one year. This is one of the most interesting and useful publications in the country, devoted to Natural History. Or a Boy's Tool Chest, 13 inches long, 8 inches wide, 8 inches deep, with a complete set of Carpenters' Tools,—Saw, Plane, etc. (The express charges on the Chest to be paid by the receiver.) For *thirty* subscribers, we will send the *Naturalist* and the "*New England Farmer*," an agricultural paper, published in Boston. For one hundred and twenty-five subscribers, a Silver Case American Watch. Price, $30.

☞ Premiums are allowed only upon *new* subscribers, not on renewals of subscription by old subscribers.

☞ Physicians, students, clerks in drug stores, young lads, etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States.

☞ Correspondents are particularly requested to give their names in full, with their Town and State; and, in case of change of residence requiring a corresponding change in the mailing of their papers, to give not only the new address, but the old one also.

☞ Subscribers who are physicians, dentists, or apothecaries will confer a favor by informing us of their profession, as we wish to know accurately the amount of our medical subscription list.

☞ We are unable to supply complete files of either Volume I. or II. of the *Journal*. Of Volume I. (originally issued bimonthly), Nos. 1, 2, and 3 (July, September and November, 1866), are now out of print. Of Volume II. (monthly), Nos. 1, 3, 6, and 12 (July, September, and December, 1867, and June, 1868), are also out of print. Of the remaining numbers we have a few copies left, which we will forward to our friends at the following prices: Volume I., three numbers, twenty-five cents; Volume II., eight numbers, fifty cents; Volume III., one dollar.

STEEL MANUFACTURING AND THE SPECTROSCOPE.

One of the most beautiful of the practical applications of the new science of spectrum analysis to the industrial arts is connected with the manufacture of steel after the Bessemer process. In this process five tons of cast iron are in *twenty minutes* converted into cast steel. We have in a former article explained to our readers that steel differs from common cheap cast iron in containing less carbon. By the Bessemer process the excess of carbon in cast iron is actually *burnt out*, while in a molten, white-hot condition, by a blast of atmospheric air, and thus converted into steel. The oxygen of the air burns out the carbon and silicon, and the heated gases issue in the form of flame from the furnace during the time that the molten iron is being burned. If cast iron contains five or six per cent of carbon, and good steel but two and a half, it will only be necessary to burn out of cast iron three and a half per cent of carbon to convert it into steel. The operation has always been a very nice and difficult one, and none but the most experienced and competent workmen could know just when to stop burning the carbon and arrest the process. If the blast were continued *ten seconds* after the proper point had been attained, or if discontinued *ten seconds* before that point was reached, the charge became either so viscid that it could not be worked, or so hard as to crumble up like cast-iron under the hammer. In short, the resultant mass would not be steel. Now, spectrum analysis steps in, and removes the difficulty in the most perfect manner. The flames issuing from the furnace contain the volatilized constituents contained in the impure iron and fuel, and by the use of the spectroscope the nature of these substances is at once detected. The complicated masses of dark absorption bands and bright lines show that a variety of substances are present in the flames in the state of a glowing gas. Among them are carbon, sodium, potassium, lithium, iron, hydrogen, and nitrogen. At a certain stage of the operation, all at once, the *carbon lines disappear*, and a continuous spectrum is observed. This is the *moment* when the air must be shut off; and, at a signal from the observer, the draft is instantly closed, and the process suspended. The spectroscope alone can thus unerringly guide in conducting this important manufacture. We naturally desire that the spectroscope should do even more in the process than has been described, and the manufacturer would like to be told whether there is any sulphur, phosphorus, or silicon in his steel, but these points it is as yet unable to determine. As these substances do not appear at all as gases in the flame, but remain unvolatilized in the molten metal, or swim on its surface in the slag of the ore, the lines peculiar to them are not seen in the flame, and consequently no aid in this direction can be expected from the spectroscope.

OUR COAL SUPPLY.

The scientific commission appointed by the British Government to thoroughly investigate the important matter of the "coal supply" in the islands have made their report, and it is pronounced "entirely satisfactory." They have succeeded in convincing the anxious subjects of the Queen that coal enough remains in the subterranean depositories to last for more than one thousand years, and so John Bull sleeps soundly again.

In this country we have never had any anxiety upon the question of supply; our concern at present is confined to another point, — how to obtain it at reasonable prices. Perhaps some of our readers may not be fully informed regarding the enormous extent of our coal-fields.

The great coal formation of this country consists, like those of other parts of the world, of beds of coal from a mere line to fifty feet in thickness, interstratified with sandstone, shale, and limestone, which constitute the great body of the formation. It is enormously developed in North America. We have first in the north-eastern part of Nova Scotia and New Brunswick a coal-field covering not far from ten thousand square miles. In the south-eastern part of Massachusetts and in Rhode Island is a deposit covering about five hundred square miles. This field, though not much worked as yet, we cannot doubt will be found hereafter to contain important seams of workable coal.

The great Appalachian coal-field, extending from New York to Alabama, — seven hundred and twenty miles in

length, — covers nearly one hundred thousand square miles. The Indiana coal-field, three hundred and fifty miles long, embraces about fifty-five thousand square miles. Another occurs in Michigan, one hundred and fifty miles long, covering about twelve thousand square miles. The Missouri and Iowa coal-fields may be set down at fifty thousand square miles. The grand total, to say nothing of fields yet further west, amounts to more than two hundred and twenty-five thousand square miles, equal to about twenty-eight such States as Massachusetts! If we suppose the average thickness of all the beds to be fifty feet (some single beds are twice that thickness), the whole amount in solid measure of the coal in the United States will be one thousand and sixty-six *cubic miles!* One cubic mile would furnish seven million tons of coal annually for one thousand years. At that rate, our coal would last one million and sixty-six thousand years.

SPOTS ON THE SUN, AND THE WEATHER.

There are many popular fallacies relating to the influence of the sun, moon and stars upon the weather, but we have never regarded as one of them, the notion that what are known as "spots" upon the sun influenced temperature upon our planet. It is certainly quite reasonable to suppose, that any opaque screen projected upon the blazing disk of the sun, would diminish the amount of heat-rays coming to us from that orb. Regarding the nature of these dark patches, we are wholly uninformed. They are known to be of immense area, for they have been accurately measured. Several have been observed which covered a space several times the diameter of our earth, and during certain years the whole equatorial region of the sun has been crowded with these spots. At the present time there are several large ones visible, and in June last they were uncommonly numerous. June was a cold, dreary month, and August was chilly, like September. It has been a cool summer, and we think it will be found that a low range of the thermometer is consequent upon the presence of these spots upon the sun's disk.

Father Secchi, the Italian astronomer, so distinguished for his spectroscopic researches, has been attentively studying this subject, and presents, in the *Giornale di Roma*, a communication in which some most interesting statements are made. He remarks that the variation of the solar spots appears confined to a period which is all but triennial. If this be so, it affords ground for hope that a law governing the appearance of the spots will be discovered which may furnish valuable data for the prediction of variations intemperature upon our planet, of the greatest importance. It is a most interesting subject for investigation, and we hope systematic researches will be instituted which will result in a great increase of our knowledge of the meteorological influences exerted upon the earth.

PERILS OF TRAVELLING IN ITALY AND THE EAST.

In one of Dr. Holland's recent letters from Europe, published in the *Springfield Republican*, he makes some most just and timely remarks regarding the "perils" attendant upon travelling and residing in the southern part of Italy, especially in Rome and Naples. We have watched by the bedside of a sick friend in the latter city, sick from malarial fever, and know that every word spoken by the doctor is true, and should be heeded by those who contemplate travelling abroad. Rome is one of the most gloomy and unhealthy cities in Europe, and a winter's residence there, to an American invalid, is most hazardous, and every way undesirable. Let no poor consumptive be deluded by the "tales of travellers," and leave a comfortable and cheerful home to pass weary days and nights in travelling, or in a residence in "sunny Italy," or the East. The most robust constitutions often succumb to the fatigues, exposures, excitements, and malaria incident to travel in those countries, and good sound health is broken and impaired oftener than is known. There is a growing disinclination on the part of sensible physicians to permit patients to leave comfortable homes in pursuit of health. If they must be set in motion, they certainly should not be allowed to cross the stormy Atlantic, for, from pretty careful observation, we are convinced there is no place in Europe where the sanitary advantages are greater than here.

A NEW ANÆSTHETIC.

A correspondent of the St. Louis *Medical and Surgical Journal*, residing at Berlin, presents some statements regarding a new anæsthetic agent discovered by Dr. Liebseich of that city, which are interesting. The term "chloral," the aldehyde of tri-chloretted acetic acid ($C_2\ Cl_3\ OH$), has long been familiar to chemists. This substance has been considerably employed in England in the manufacture of chloroform by simple double decomposition between it and caustic soda. This "chloral" is the new anæsthetic of Dr. Liebseich. It is a colorless fluid, of penetrating odor, but almost without taste, and is obtained by the action of chlorine gas upon alcohol. It is thought from the experiments made with it that it will, in many cases, prove superior to chloroform or ether. Its action is slow, but the sleep, stupor, or insensibility may be continued for hours without causing headache, or any unpleasant symptoms. It is thought that it will not supersede the agents in use, but it will fill a gap which they do not cover. In cases of insomnia from general suffering, or mental excitement, it may prove of great service. If so, it will indeed be a boon to suffering humanity.

POPULAR LECTURES.

The season of the year has arrived when lyceums and library associations are making arrangements for courses of popular lectures. These lectures are generally such as do not add to the stock of general information, or improve the mind or heart. Popular sensational preachers, noisy politicians, and story-writers, have been the most sought after to fill the lecturer's desk. We hope to notice an improvement in the public taste the coming winter, and that lectures upon science, the mechanic arts, history, geography, etc., will take the place of the worthless declamatory productions heretofore so popular. We find in the report of the executive committee of the Peabody Academy of Science, recently published, some most truthful and timely observations upon the subject of popular lecturers, which we copy. The Report is written by Wm. C. Endicott, Esq., of Salem, Mass., President of the Academy.

"And here it may be remarked that lectures affording solid instruction in an agreeable and interesting way are much needed in this community. The persons who for the most part supply the popular lecture platforms are either professional lecturers, given to sensational, declamatory, fine writing, — gentlemen of some general reputation obtained in other fields, — or the advocates of some particular hobby or reform. Lectures are given and attended, not for instruction and improvement, but to gratify curiosity, or to afford amusement and excitement to audiences. The result is, that the lecture now seldom instructs. Aiming at other ends, the modest rewards of the scholar and man of science are no longer the measure of payment, and prices have risen to an exorbitant rate. Lecturers swell their incomes by a winter's tour at one or two hundred dollars a night. They are paid as opera-singers are paid. The lecture platform is thus forced to pay a heavy tribute, and in the smaller towns and communities the performance is beyond the reach of the people. It would be idle, even if it were desirable, to attempt a change in this condition of things, or to enter into a crusade against the present system; but it would seem that much might be done in this county by an institution like this, co-operating with local societies, to furnish that which the lyceums no longer supply.

MAILING THE JOURNAL.

We have to apologize for the delay in mailing the two last numbers of the *Journal*. So large have been the editions, that, with all the force that could be employed in the mailing-room, the whole could not be sent away in less than *two weeks* from the day of publication. To remedy this, we have, at large expense, adopted the "Dick" system of mailing and book-keeping, and soon our subscribers will find upon each number of the *Journal* the little printed slip of yellow paper, containing the subscriber's name and the date to which subscription moneys have been paid. This will save all duns and errors, we trust, and greatly facilitate the speedy and correct delivery of every number.

THE GREAT ECLIPSE. — To thousands of our readers residing in Iowa, Illinois, Kentucky, the Carolinas, etc., the late eclipse of the sun was indeed *great*, because it was *total*. To those residing in the Eastern States, the spectacle was less sublime and wonderful; but still the amount of "smoked glass" brought into requisition was as large as that employed in more favored localities. The day was clear and favorable so far as we have learned, and the millions of eyes upturned to the great luminary were able to watch the phenomenon from the beginning to the close. The exact scientific observations of astronomers, with their delicate instruments, — the telescopes, spectroscopes, photographic apparatus, barometers, thermometers, hygrometers, etc., etc., — have not yet been presented to us in detail, but we shall soon have them. How exact and wonderful are the deductions of science! At precisely the instant of time predicted, our satellite impinged its broad disk upon that of the sun, and the whole affair was in perfect accord with mathematical results. How few of the many great facts in astronomical science would enter into the popular belief, if there were not some astounding demonstrable results, like the calculation of eclipses, the transits of stars, the movements of the great tidal wave over our earth, etc., etc.!

The statement that iron, chromium, barium, and other metals have been found in the photosphere of the sun, at a distance of 95,000,000 of miles from us, is only assented to as true, because of the proved exactness of eclipse calculations. The same may be said of the wonderful deductions of the other sciences; and fortunate indeed is it for the world that eclipses occur, and that the chemist can burn iron, steel, diamonds, and the most refractory substances with as much ease as shavings of wood, as thereby confidence is established in those sublime truths of science which do not admit of popular demonstration.

Bradford Academy.—The reader's attention is called to the advertising department of the *Journal*, where will be found the modest announcement of the school-term of Bradford Academy. This institution, as is well known, is one of the most excellent and trustworthy of our many schools for young ladies. It has a history interesting and honorable. The new and magnificent school-building, erected at a cost of *one hundred thousand dollars*, occupies a position of unsurpassed, picturesque beauty, commanding a view of the valley of the Merrimack for several miles, and of the city of Haverhill throughout its entire extent. We believe this structure to combine more comforts, conveniences, and excellences, as a school for ladies, than any other in the country. Parents can send their daughters to Bradford Academy with the fullest assurance that they are *safe;* that they will be cared for, watched over in sickness and in health, and be thoroughly instructed and trained, morally, intellectually, and physically. We make these remarks because we have long known of the high character of this institution, and because we also know that, in many households where the *Journal* is received and read, the anxious inquiry is often made, "To whom shall we intrust the education of our daughters?"

☞ The *Journal* of the *Gynæcological* Society of this city made its appearance in July under the editorial charge of Prof. Storer and Dr. Lewis. It promises to be a very able and useful medical publication, and one which every practitioner will need to have upon his table. The extensive experience and high scientific attainments of the editors and conductors is a sufficient guarantee that the *Journal* will be an important addition to American medical literature. It should be generously sustained by the profession.

Preserving Fruits.—This is the season for canning fruits and vegetables for winter use, and we advise our friends to provide a generous store of these luxuries. The jar or can which we have tried and found most convenient and perfect is what is known as "Moore's Patent," manufactured by Messrs. Moore & Co., Clayton, N. J. The jars and lids being all made of glass, there is no metallic contact with the fruits, and no part to rust or corrode. A simple turn of a screw on the top of the jars fastens the cover, and hermetically seals the package. It is a most convenient and excellent device.

☞ It is apparent from an item under the editorial head found in the issue of the *Boston Medical and Surgical Journal*, July 12, that the editor is greatly troubled with—*worms!* It is a bad case: who will prescribe?

BOOK NOTICES.

On the Detection of Red and White Corpuscles in Blood-stains. By Joseph L. Richardson, Microscopist to the Pennsylvania Hospital.

The above is the title of a very interesting medico-legal paper in the July, 1869, number of the *American Journal of Medical Science.* In murder trials the question arises as to whether certain blood-stains upon the prisoner's clothing are those of human blood. By macerating in pure water a portion of the stain under a 1-25 immersion objective, Dr. R. finds the red corpuscles distended and almost broken, and yet capable of measurement with a cobweb micrometer. The elaborate researches of Carl Schmidt and others in regard to the exact variation of size among the blood-corpuscles in different species of vertebrates, having been laid before the profession, and Dr. Richardson having shown how the corpuscles in stains may be detected and measured, we see that a valuable contribution has been made to medical jurisprudence. We welcome cordially any addition to the literature of blood morphology; but can Dr. Richardson expect credence with his three or four experiments and mensurations of *ten* red blood-corpuscles, when influential and reputable *savans*, so called, thrust Dr. Salisbury aside, with his tens of thousands of observations, extended over a long space of time, as unworthy of anything but ridicule?

Medicine and Pharmacy.

HAY-FEVER.

The month of August is the time when the disease known as "hay-fever" prevails in all its disagreeable intensity. It is certainly a most extraordinary and baffling affection, and one which is unmistakably on the increase in the Northern States. Formerly, say thirty years ago, it was rare to find a case in a wide circle of practice; now it really seems as if there were hardly a neighborhood in which less than a dozen victims are found. Thus far, the disease has resisted all methods of treatment; and physicians can only send their patients to the seashore, or to the mountains, with any hope of relief. Some forms of the affection are relieved by a seaside residence; others are not in the slightest degree mitigated. We know of a gentleman who is relieved when in a boat on the salt water; but the instant he touches land, it returns with unusual violence. The neighborhood of the White Mountains appears to be the most favorable locality for relief from suffering. A large number of persons have been cured by a residence at Gorham and Conway, N. H. Probably the most judicious advice a physician can give a hay-fever patient is, to recommend a trip to, or residence at, the mountains during the season when the attack is expected.

What is the cause of this singular affection? Who can reply? A lady informs us that it is brought on in her case by passing over a certain road in which there is a depression of a dozen rods in extent. She is well enough until this depression is reached, when she instantly begins to sneeze, the eyes become filled with water, and the nose and throat with mucus. By the time she reaches the other side, the disease is firmly established. Another states that the odor of an apple in a room, or in the hand of a person, will bring on the affection; another, that flowers or new-mown hay will cause it; and still another is positive that a certain room in a house cannot be visited in August without resulting in a violent attack. It assumes the form of violent catarrh, and is attended with exquisite suffering in many instances. The time of continuance is from four to eight weeks. Two instances have come under our observation, in which, after about four weeks' duration, typhoidal symptoms set in; and the fever clung to the patient far into October.

We have waited anxiously for the treatise upon this subject which it is understood Dr. Wyman, of Cambridge, has for several years contemplated preparing. He is a victim to the disease himself, and has taken great pains to collect facts and study cases, so that in such able hands we may expect an interesting and exhaustive treatise, which is much needed by the profession.

Recently it has been asserted that the affection is caused by the presence of *vibriones* in the atmosphere, and that great irritation results from their contact with the mucous surfaces of the upper air-passages. A distinguished *savan*, Helmholz, reports in *Virchow's Archiv* that he has succeeded in finding vibrios in his own nasal secretions, when suffering from this form of catarrh. He also states that a saturated neutral solution of quinine dropped into the nasal passages afforded immediate relief. We are ready to welcome any reliable researches which will throw light upon this subject, and through which a remedy may be pointed out.

Subcutaneous Injection of Morphia.—It is certain that one of the most important aids to the physician in his professional labors is the employment of remedies subcutaneously. If this method were confined alone to one agent, morphia, it ought to confer immortality upon the discoverer. We have ourselves experienced the immense value of this form of employment of the alkaloids of opium, and cannot too fully express our thankfulness for its benefits.

If the instruments used are perfectly clean, and the solution free from extraneous bodies, we do not believe unpleasant results will ever occur when morphia is injected under the skin. In this form, the drug acts with much greater intensity and rapidity; the duration of its effects is prolonged; it is well tolerated by the stomach; does not produce cerebral disturbance; seldom constipates the bowels; in short, morphia hypodermically used becomes, so to speak, a new remedy, or an old one with its value a thousand times enhanced.

In cases of insomnia, resulting from excited nervous action, its employment in this form affords the physician a ready and safe means of relieving his suffering patient. Acute pain, from bowel affections, rheumatism, etc., is almost instantly mitigated, and the patient put in condition to be favorably influenced by such other remedies as the case may require. In short, there is no form of disease in which morphia is better given by the mouth than placed under the skin.

The initial dose for an adult man is regarded to be from one-sixth to one-fourth grain; for a woman, it should be smaller,—from one-eighth to one-sixth. We prefer the acetate to any of the other salts of morphia; indeed, it is difficult to understand how the sulphate of morphia came to be more favorably regarded by physicians than the acetate. An organic acid, in combination with the alkaloid, certainly more exactly corresponds with its natural condition, as it exists in the dried juice of the poppy; and theoretically we ought to regard it with favor.

A NEW MYRRH MIXTURE.

Editor Boston Journal of Chemistry:

I send you a formula for a myrrh mixture which I have prepared here, and find very useful as a tonic in place of the Griffiths mixture. It will keep any length of time, and is quite agreeable to the taste. Dose, one to two teaspoonfuls half an hour after each meal.

You are at liberty to publish it, with any improvement you may think proper.

Yours truly,

H. H. Hill, M. D.

Augusta, Me., July 29, 1869.

MIXTURE OF MYRRH AND PYROPHOSPHATE OF IRON.

℞.	Gum myrrh Turkey,		
	Pyrophos. iron,	āā.	℥ij.
	Sugar,		℥v.
	Tinct. ol. gaultheria,		ʒx.
	Brandy,		℈ss.
	Aqua,		℈iij ss.
	Carb. magnesia,		℥j.

Tincture the myrrh with the brandy, then mix the tinctures with the magnesia and sugar rubbed together, add the water gradually and filter. Then add the iron, and, when fully dissolved, filter again. Alcohol may be substituted for the brandy.

TREATMENT OF BURNS.

Editor Boston Journal of Chemistry:

The frequent difficulty experienced by physicians in affording prompt relief in cases of burns induces me to offer to them, through your paper, two remedies or applications which have served me well in the cases above named: frequently affording almost *instant relief* to pain, and preventing the separation of the cuticle in cases where a blister seemed inevitable. The first is, to envelop the injured part immediately with the pulp of the *raw potato*. The second is, to apply linen cloths, dipped in a mixture of sweet cream and *subnitrate of bismuth*, in the proportion of one ounce of the latter to a pint of the former, repeated once in two or three hours. In cases which are first visited three or four days after the accident, I have found the latter application to answer the best of the two.

A. H. Lamphear, M. D.

Atchison, Kansas, Aug. 9, 1869.

VOLATILE LINIMENT.

Editor Journal of Chemistry:

I wish to call attention to a new formula for volatile liniment. I propose to substitute cod-liver for olive oil, thus:

℞. Liquor ammoniæ, f ℥ j
Oleum morrhuæ, f ʒ ij M.

Such a formula may have been used before, but if so I have never seen it. It makes an elegant preparation, and combines a tonic effect with that of the liniment. It is a valuable mode of administering the oil by inunction in chronic and wasting diseases of children, rheumatism, etc.

G. W. H. Kemper, M. D.

Munice, Ind., Aug. 10, 1869.

Cincho-Quinine. — *Messrs. J. R. Nichols & Co.:* The specimen of cincho-quinine which you sent me has been received, and I have had a patient with remittent fever who could not take the sulphate of quinine on account of an irritable stomach, and to whom I gave the cincho-quinine. It was not only retained, but did not affect the stomach or brain unpleasantly in the least degree. It was a little boy of about six years of age, and a fine specimen of the nervous temperament.

I will be much obliged if you will send me two ounces cincho-quinine by express, as I have several patients who cannot take the sulphate, and the season is at hand when a substitute must be had.

A. Donald, M. D.

Demopolis, Ala.

CHEMISTRY AND PHARMACY.

The "New Nomenclature" in chemistry is now adopted by nearly all teachers of that science, and ere long the old technical vocabulary will probably have fallen into disuse, and new generations of graduates will come into our ranks, speaking a chemical language unknown to many of us, and not comprehending the obsolete terms which older practitioners will continue to employ. The younger man may possibly guess what is meant by "sulphuretted hydrogen"; but his older companion will not know what compound is intended by the term "dihydric sulphide." Senex, who may be thoroughly conversant with the effects of "carbonic acid," will not be apt to imagine that Juventus applies to this gas the appellation of "carbonic dioxide," but will refer it to the only "carbonic oxide" of which his former reading has informed him.

Such misunderstandings, however, are of minor importance; for medical men are not as a rule prone to enter upon very profound chemical discussions in their ordinary colloquial intercourse. But there is a graver side to the question, which bears upon the practical, every-day business of our profession; and this relates to the matter (or rather to the manner) of prescribing.

Chemistry is the parent of Pharmacy, and its phrases and formulas are laws to its offspring. The new nomenclature, involving, as it does, a vast number of compounds used for medicinal purposes, and being likely to be exclusively taught to future dispensing druggists, must ultimately necessitate material changes in our pharmacopœia. In some respects the alteration would be desirable, inasmuch as many of the terms derived from older chemistry are inaccurate in the light of modern science, and their retention serves to perpetuate error: but if the change be thorough, — if things are to be "called by their right names," — "confusion worse confounded" will reign among prescribers of the old school. We shall have to learn that calomel is "*mercurous chloride*" and corrosive sublimate "*mercuric chloride*," and that, consequently, abbreviations must be renounced, since "mercur. chlorid." would apply to either; that "*spiritus etheris nitrici*" is not spirits of nitric ether at all, but an alcoholic solution of "*ethylic nitrite*"; that "*sulphuric ether*" contains no suspicion of sulphur, but should be written "*ethylic ether*"; and many other pieces of new information. To be sure, our convenient abbreviations will still answer for some substances: "*sod. chlorid.*" and "*potass. iodid.*" will apply as well to "*sodic chloride*" and "*potassic iodide*" as to the titles by which those drugs are now dispensed, and, as a good many prescribers know the remedies they use only by such abbreviated "nicknames," the alteration will not give them much concern.

It is evidently proper that the pharmacopœia should be in accordance with scientific chemistry; and it is certainly necessary that medical prescriptions should be in accordance with the pharmacopœia, even if the majority of the profession be forced to go to school again. For our own part, we should welcome any measure which would lead to greater care in writing prescriptions, and better acquaintance with some of the substances to which prescriptions relate. — *New York Medical Gazette.*

☞ Dr. C. W. Davis, of Indianola, Iowa, writes that he has treated several cases of "Sulphuretted Hydrogen Dyspepsia" successfully, by the use of the following mixture:

Nichols' solution carbolic acid, }
Pure glycerine, } ea. ʒi.
Peppermint water, } (Mix.)

Use teaspoonful as a gargle, cleansing the throat, fauces, and mouth well; after which, take from 15 to 20 drops of the same mixture internally. By using the carbolic acid mixture, as above directed, the most offensive and fœtid breath can be rendered sweet, and offensive eructations prevented.

Prophylaxis of Scarlet Fever and Measles. — Dr. J. C. Peters makes this suggestion in the *New York Medical Gazette:*

It often becomes necessary or desirable to give some remedy which is supposed or believed to be preventive, or ameliorative of these diseases. Belladonna is unreliable in small doses and dangerous in large quantities. Besides, its effects are so similar to those of scarlet fever that the physician may be plunged in doubt as to which is the effect of the remedy, and which of the disease, when it has been given antecedently, both long and frequently. I have seen many children escape after great exposure to scarlet fever without the use of any prophylactic, or precautionary treatment; and I have seen it occur in a malignant and fatal form after Belladonna had been given regularly for two or three weeks before the occurrence of the attack. I now never use Belladonna to prevent scarlet fever, but rely entirely upon the sweet Spirits of Nitre. This is a mild and safe remedy which can complicate the disease in no possible way. It lessens the fever and restlessness, and prevents the occurrence of disease of the kidneys. As a diuretic, it may eliminate the poison so rapidly and completely, that the system cannot become affected, nor the disease reach its full and fatal development. Comparative experiments prove that it is more reliable than Belladonna, and far more safe.

Employment of Glycerine of Tannin. — Dr. Sidney Ringer (*The Practitioner*) states this preparation of tannin is very useful in many diseases. It is not laid down in the United States Dispensatory, but Adolphe Wahltuch, M. D., alludes to the following formula for its preparation in the *Dictionary of Materia Medica and Therapeutics:*

℞ Gallic acid, ℥ i.
Glycerine, f ℥ iv.

Rub and heat. In ozæna, this combination is highly prized by Dr. Ringer. He also recommends it in the thin sanious or thicker purulent discharge from the nostrils which sometimes occurs after measles and scarlatina; in the obstruction of the nose frequent in syphilitic children. The purulent discharge from the ears, so often met with in unhealthy children, can be stopped at once by filling up the internal meatus with this preparation. If there be acute inflammation of the meatus, this should be relieved before using the tannin.

Tincture of Paullinia. — M. Stanislas Martin, in the *Bulletin de la Therapeutique*, says that the *Paullinia*, which in Brazil, whence it comes, bears the name of "Guarana," is prepared by the Manheem Indians. According to Riadel, he says, it is a compound of tapioca farina, of cocoa and of paullinia seeds, made into a homogeneous paste, and dried in the sun. The names of medical men in Brazil are cited as having praised the drug as a tonic, anodyne and febrifuge. Dr. Martin's analysis showed it to be composed of glycyrrhizin, albumen, gallic acid, bitter resin, fatty matter, and vegetable (including woody) extractive matter. At Rio de Janeiro this substance is given in powder, or made into pills, pastilles or tincture. Since 1846 it has had a place in French therapeutics, being employed in France in the form of powder, or dissolved in alcohol. Dr. M. proposes the following formula for the tincture:

℞ Paullinia in impalpable powder, 100 parts.
Alcohol at 80 degrees, 250 parts.
Distilled water, 250 parts.

Macerate for fifteen days in a bath heated to ten degrees (centigrade), taking care to agitate frequently. Express, and filter through paper.

Treatment of the Vomiting in Colic. — Dr. George Atwood, of Fairhaven, Mass., recommends, in the *Boston Medical and Surgical Journal* for July 23, 1868, p. 393, the treatment of common colic by the hypodermic injection of morphia, in the dose of one-third or one-half a grain of the acetate or sulphate in the smallest quantity of water, thrown into the arm. If, after waiting ten or fifteen minutes, any pain should remain, the dose may be repeated.

One or two teaspoonfuls of the tincture of lobelia, in a quart of water, thrown up the rectum, will, in the early stage of colic, afford immediate relief. It is much safer and more efficacious than Dr. Mackintosh's tobacco injection.

Treatment in Diarrhœa of Infants. — Dr. Smith (*Medical News and Library*), in his valuable papers on the "Wasting Diseases of Infants and Children," recommends the following prescription, if the bowels are rather loose, with dark, slimy, offensive stools:

℞ Tinct. opii, ♏ viii.
Ol. ricini, ʒ j.
Syrupi zingib.
Mucilag. acaciæ, āā ℥ j.

M. S. A teaspoonful three times daily. In the screaming fits, accompanied by constipation, this combination of castor-oil with laudanum is very valuable.

A Soluble Salt of Mercury for Hypodermic Injections.—M. Couilhon suggests, in a late number (15th April) of the *Bulletin de Therapeutique*, a solution of the double iodide of mercury and sodium for hypodermic injections. It is soluble in water without decomposition; it is active, yet not irritating to the tissues; it is manageable and safe. One and a half parts of this (by weight) in one hundred parts of water gives a solution, of which ten drops can be administered every other day in syphilis. After a week or two, the amount of the injection can be increased ten drops at a time. — *Medical Archives.*

Dr. Pavy, of Guy's Hospital, recommends opium or morphia as exerting a controlling (in one case curative) influence in diabetes. He begins with large doses, — half a grain of morphia three times a day, — and increases according to effects.

For chills, chronic with anæmia, —

℞. Acid arseniosi, gr. jss.
Quin sulph.
Ferri sulph. (exsiccat,) aa ʒ j.
Morph. sulph., gr. j.
Ext. nucis vomicæ, ℈ j. M.

In pil. xxx ft. S. — One three times a day.

Dr. King (*Medical and Surgical Reporter*) has used permanganate of potassa with the happiest results in rheumatism. His formula is, —

℞. Permanganate of potassa, gr. ij.
Syrup of Sarsaparilla, ℥ j.

One teaspoonful to be taken three times a day.

BOSTON JOURNAL OF CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. IV.—No. 4. BOSTON, OCTOBER 1, 1869. FIFTY CENTS PER ANNUM. SINGLE NUMBERS, SIX CENTS.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.

RECEIPTS.—A receipted bill will be sent by return mail to any subscriber who will enclose with his subscription a three-cent postage stamp, return postage.

A list of premiums is offered to those who obtain subscribers.

Contents.

Familiar Science.

THE HAIR: HAIR DYES AND WASHES.

The deep interest felt in the welfare of the natural covering to the head is evinced by the expenditure of much time and large sums of money in attempts to preserve and adorn it by all classes of people. Upon no subject have we been more frequently requested to express opinions or supply information than upon that of the hair, and the increasing demand for dyes, washes, and "preservatives" indicates how wide-spread and well nigh universal is the interest in the matter. These considerations have led us to make some observations upon the hair, and the substances used to change its tints and improve its condition.

The adornment of the hair, and the forming of it into fantastic shapes, has been practised by women in all ages, and in no direction have the caprices of fashion been more strikingly displayed than in disposing this natural covering of the head. The early Hebrew women gloried in their luxuriant tresses, plaiting them, and adorning their heads with ornaments of gold, silver, and precious stones. The Greeks allowed their hair to grow to a great length, while the Egyptians often removed it as an incumbrance. There is no "fashion" connected with the hair, in vogue at the present time, which is new. It is not a modern idea to resort to borrowed or "false" hair to satisfy the caprices of fashion, neither is it to dye the hair, or dress it with unguents and oily substances.

The Greek, Egyptian, Carthaginian, and Roman ladies, more than twenty-five centuries ago, made use of the most extravagant quantities of borrowed hair, and they wound it into large protuberances upon the back of their heads, and to keep it in place used "hair-pins" of precisely the form in use at the present time. The Roman women of the time of Augustus were especially pleased when they could outdo their rivals in piling upon their heads the highest tower of borrowed locks. They also arranged rows of curls formally around the sides of the head, and often the very fashionable damsels would have pendent curls in addition. An extensive commerce was carried on in hair, and after the conquest of Gaul, blonde hair, such as was grown upon the heads of German girls, became fashionable at Rome, and many a poor child of the forests upon the banks of the Rhine, parted with her locks to adorn the wives and daughters of the proud conquerors. The great Cæsar indeed, in a most cruel manner, cut off the hair of the vanquished Gauls and sent it to the Roman market for sale, and the cropped head was regarded in the conquered provinces as a badge of slavery.

To such a pitch of absurd extravagance did the Roman ladies at one time carry the business of adorning the hair, that upon the introduction of Christianity, in the first and second centuries, the apostles and fathers of the church launched severe invectives against the vanity and frivolity of the practice. It must be confessed the ancient ladies did outdo their modern sisters. The artistic, professional hair-dressers of old Rome were employed at exorbitant prices to form the hair into fanciful devices, such as harps, diadems, wreaths, emblems of public temples and conquered cities, or to plait it into an incredible number of tresses, which were often lengthened by ribbons so as to reach to the feet, and loaded with pearls and clasps of gold. No wonder such exhibitions of vanity excited the wrath of that stubborn old bachelor, St. Paul, and called forth his maledictions. It would be curious if, before the present fashion of arranging the hair among the ladies burns out, the extreme customs of a pagan age should come round again.

In ancient times, people grew old as they do now, and the frosts of age blanched the raven locks of youth, and also there were those with hair glowing with red, or other tints not deemed desirable. Hence it was that hair dyes came into use, and a brisk demand for substances capable of changing the color of the hair has been maintained for thirty centuries.

The substances employed before the science of chemistry was understood, were usually quite ineffective in their influence. They were, for the most part, fugitive vegetable stains, which water would easily remove. There was, however, a metallic mixture made in Egypt which possessed qualities of the highest excellence. If the statements of some writers can be relied upon, this mixture was far superior to any form of hair-dye known to modern chemists. There is at the present time a dye used by the Armenians, in the East, which may be, in many respects, like the ancient dye. It is a metallic substance, resembling dross. This is powdered, and mixed with fine nut-galls and moistened. A little of the paste is taken in the hand and rubbed into the hair or beard, and in a few days it becomes beautifully black. Those who have visited the Armenian convents in Turkey can but have admired the fine black beards of the monks, even those of advanced age. This dye is undoubtedly composed of a mixture of iron and copper, which metals, in conjunction with the gallic acid formed from the galls, produces a dye of superior excellence.

The hair dyes in use at the present time are, for the most part, objectionable in some one of their features, or they are untidy or inconvenient to apply. The dye which has been so fashionable during the past ten years is a poisonous compound, being composed largely of one of the salts of lead, (the acetate.) This mixture was brought into notice soon after the close of the Mexican war, and was known as "General Twiggs' hair dye," the General of that name having first successfully used it. Nearly all the "Restoratives," "Washes," "Embrocations," "Dressings," "Dyes," etc., found in the shops are identical in composition, being made from this formula. The number of popular mixtures of this kind, having different names, and which were made and sold by different parties, at one time exceeded *forty* in the

United States. The formula and method of preparing it is exceedingly simple. Take of

Finely powdered Acetate of Lead — 120 grains.
Lac Sulphur — 160 grains.
Rose Water — one pint.
Glycerine — one ounce.

Mix the glycerine with the water, and add the acetate of lead and sulphur. The mixture must be well shaken before using. The lead and sulphur do not all dissolve in the rose-water, but fall to the bottom of the vessel as a precipitate. This preparation will gradually dye the hair a black or dark brown color if a small quantity is rubbed into it once or twice a day. Its frequent use is however attended with great danger, as numerous instances of lead poisoning have resulted from its employment. There are many other hair dyes into which lead enters which are equally objectionable. The following is a well-known formula:

Powdered Litharge (oxide of lead) 2 oz.
Quicklime — ½ oz.
Calcined Magnesia — ½ oz.

Mix the powders, moisten with water, and apply the paste to the hair and allow it to remain four hours. This affords a dark brown color; for a deep black, it must remain eight hours.

The solution of plumbate of potash is a very convenient dye. It is slow in its action, but it does not stain the skin. It is prepared by dissolving in four ounces of liquor of potassæ as much freshly precipitated oxide of lead as it will take up, and dilute the resulting clear solution with twelve ounces of pure water. It may be applied as a wash to the hair. The permanganate of potassa forms an excellent dye, where a dark-brown color is desired. It is safe and easily applied, but it has the disadvantage of staining the skin. If care is used, this need not occur. The solution may be made by dissolving in two ounces of distilled water 120 grains of the crystals of permanganate of potassa.

One of the most common forms of hair-dye, as found in the shops, is prepared from nitrate of silver.

Nitrate of silver, 1 oz.
Rose-water, 7 oz.
Dissolve the silver in the rose-water.

This is the dye. Previous to applying it to the hair, it must be wet with the following solution:

Sulphuret of potassium, 1 oz.
Water, 6 oz.

After the hair is dry, the silver solution is applied with a brush. The odor of the mordant is very disagreeable; and this dye, although very quick and certain in action, cannot be regarded as very desirable. An inodorous silver dye is prepared as follows: Dissolve one ounce of nitrate of silver in six ounces of water, then add liquor ammonia by degrees, until the solution becomes cloudy from the formation of oxide of silver; continue to add ammonia until it becomes clear again from the re-dissolving of the oxide of silver. This is the dye. Before applying it, the hair must be washed in a solution of pyrogallic acid, made by dissolving sixty grains of the acid in eight ounces of rose-water. This is an excellent and safe dye; but its employment is attended with some trouble, and care must be used. A large number of other formulas for hair-dyes, might be given, but these are sufficient. Their nature and methods of use will be readily understood.

The frequent use of "oils," "bear's grease," "arctusine," "pomades," "lustrals," "rosemary washes," etc., etc., upon the hair, is a practice not to be commended. All of these oils and greasy pomades are manufactured from lard-oil and simple lard. No "bear's grease" is ever used. If it could be procured readily, it should not be applied to the hair, as it is the most rank and filthy of all the animal fats. There are many persons whose hair is naturally dry and crisp, and in most families there is a want of some innocent and agreeable wash or dressing which may be used moderately and judiciously. The mixture which may be regarded as the most agreeable, cleanly and safe is composed of cologne spirit and pure castor-oil. The following is a good formula:

Pure, fresh castor-oil, 2 oz.
Cologne spirit (95 per cent), 16 oz.

The oil is freely dissolved in the spirit, and the solution is clear and beautiful. It may be perfumed in any way to suit the fancy of the purchaser. The oil of the castor-bean has for many years been employed to dress the hair, both among the savage and civilized nations, and it possesses properties which admirably adapt it to this use. It does not rapidly dry, and no gummy, offensive residuum remains after taking on the chemical changes which occur in all oils upon exposure to light and air. It is best diffused by the agency of strong spirit, in which it dissolves. The alcohol or spirit rapidly evaporates, and does not in the slightest degree injure the texture of the hair. This preparation, for dressing the hair of children or ladies, will meet nearly or quite all requirements. A cheap and very good dressing is made by dissolving four ounces of perfectly pure, dense glycerine in twelve ounces of rose-water. Glycerine evaporates only at high temperatures, and therefore under its influence the hair is retained in a moist condition for a long time. As a class, the vegetable oils are better for the hair than animal oils. They do not become rancid and offensive so readily, and they are subject to different and less objectionable chemical changes. Olive-oil and that derived from the cocoanut have been largely employed, but they are inferior in every respect to that from the castor-bean.

It is doubtful if any mixture or substance has ever been devised which will restore hair to a bald head. A great many washes and embrocations are manufactured, all of which usually fail to meet the end desired. The falling of the hair is the result of diseased action in the hair follicles, or to a morbid condition of the entire scalp. When a hair is pulled out "by its roots," its base exhibits a bulbous enlargement of which the exterior is tolerably firm, whilst its interior is occupied by a softer substance which is known as the "pulp"; and it is to the continued augmentation of this pulp in the deepest part of the follicle, and to its conversion into the peculiar substance of the hair when it has been pushed upwards to its narrow neck, that the *growth* of the hair is due. A hair does not begin to grow from the true skin, but originates in the *epidermis*, and is essentially like that covering, being composed of aggregations of cells filled with horny matter, and frequently much altered in form. Hence it will be understood how difficult it is to excite action in a part possessed of such low vitality, and how poor the prospect must be of compelling hair to grow by any stimulus externally applied. Still, mixtures containing ammonia, vinegar, soap and vesicating tinctures are sometimes thought to prove beneficial. The fall of the hair will usually cease from natural causes in a short time, the germinal vessels taking on healthy action spontaneously. The frequent washing of the head in tepid or cold water, and friction with a brush or coarse towel, is to be commended.

The English artisans are making window sashes of copper, which is much better than wood.

THE MOON.

The late eclipse, so interesting and wonderful in all its aspects, has naturally awakened a new interest regarding the physical character, not only of the great solar orb, but of our beautiful satellite, the moon. A correspondent sends us some observations which, we think, will interest our juvenile readers, if they do not those of more advanced years. He remarks:

There are some *queer things* about our amiable celestial companion. In the first place, *she never shows us but one of her sides.* Is it possible that she is a dissembler, after all, and has anything to conceal? Scarcely. We had much rather attribute her conduct in this respect to *eccentricity.* Whatever may be her motives, the fact that we never see but one side of her is easily explained. It takes her a little more than twenty-seven days to revolve once around our earth — and it so happens that she requires *just as long a time* to revolve once on her own axis.

To explain this, let any one of your young readers place an apple, to represent the earth, on a table in the centre of a circle. Let another apple, to represent the moon, be moved in the circle around the central apple, care being taken to keep the *same side* of the moving apple always turned towards the apple in the centre. It will be found that when the revolving apple has completed a circle round the stationary one, it has made one revolution on its own axis. It is clear that a fly stationed on the central apple, even if he follows the moving apple all the way round, never sees but one side of it. This is a singular arrangement, and, whether or not we *know* what it means, it doubtless means *something.*

There is another sense in which our *secondary* is *one-sided.* Let us explain: Suppose we take a round ball of wood, and bore a hole from one side into the exact centre. Now, if the ball is exactly even and we insert a wire until it reaches the exact centre, the ball will be balanced upon that point. But suppose that, after we have done this, we bore another hole in the side of the ball, and fill it with lead, and try to balance the ball now on the centre, — what will be the result? Of course it will not balance, but the side on which the lead is will overbalance the other; and, if we wish to balance the ball now, we must find a point somewhere away from its centre, and on that side of the ball which contains the lead. The centre which we *first* found is the *centre of the figure*, while the *balancing* point is called the *centre of gravity.* Exactly so with the moon. The *centre of her figure is different from her centre of gravity*, and the heavier side is that which is always turned from the earth. What a singular fact have we here!

The question is often asked, if the moon is inhabited. Let us speculate a little. Of course it is meant, inhabited by beings similar to the inhabitants of the earth, for we have no knowledge of any other.

It is certain that the moon keeps whatever she has on her surface by the force of *attraction of gravitation.* Gravitation is only another name for *weight*, and everybody knows that everything that has weight seeks to get as low as possible, and will fall unless sustained by some other power; that is, all bodies on the earth would, if not prevented, fly at once to the centre of the earth. We say water seeks its level. What is this but saying that water gets as near the centre of the earth, which is her centre of gravity, as possible? and just so with the atmosphere.

It is precisely the same with the moon. If there is any atmosphere around her, it will get just as near her centre of gravity as it can; and, if it can get nearer by

going all on one side of the moon, it will be sure to go there.

But suppose it cannot *all* get on one side; then a little may extend over on the other hemisphere. *Perhaps* this accounts for the fact that philosophers, seeing only one side of our satellite, for a long time believed there was no atmosphere around the moon; while more accurate instruments and experiments seem to reveal the existence of a very slight and thick atmospheric covering. Now, unless things are very different in the moon from what they are on the earth, where there is no atmosphere, it is difficult to see how there can be any water; and besides, if the water is free to flow, that, too, would all accumulate on one side of the moon, — that is, on the side which we never see. How can beings like those on the earth live where there is neither air nor water? But it may be said, "How do we know but such beings may live on the *other* side of the moon?"

Well, perhaps they do. If so, we pity them, — if for no other reason than that they can never see a moonlight night. If the proverbial "man in the moon" lives on our side of that orb, to him our earth is a moon, and is always over him and always full. Look at the two apples again, and see if it is not so. If we cannot see the far side of the moon, our earth cannot be seen from that side; consequently that side has no moon.

And thus, again, as the moon turns on her axis only once in about twenty-eight days, *her day is equal to twenty-eight of our days*, — fourteen days of light and fourteen days of darkness. Such a state of things would be anything but agreeable to us. The sun blazing with all his power for fourteen days continually, without once setting, would, unless modified by other causes, produce a parching heat; and then fourteen days of darkness, with not a ray of sunlight or heat, and no moonlight on one of her sides, would be attended with an intense degree of cold. Such an arrangement does not seem very well adapted to the support of life in such creatures as we are.

But we might extend our speculations *ad infinitum*.

Arts.

ADULTERATION IN FOOD.

Editor Journal of Chemistry:

Your article on "Adulterations," in the last number of *Journal*, is timely and truthful; but, having had some experience in the investigation of this subject, I must differ from you in one or two points. You say, "If every housekeeper would demand of his grocer pure spices, sugars, cream of tartar, etc., he would fare much better than he now does." Perhaps he might fare a *little better*; but the main difficulty would remain, as I know by experience. I once bought some ground coffee, "warranted pure." It proved to be largely adulterated with chickory. On returning it, the dealer said he could not depend on the grinder. I then inquired his price for the same coffee roasted, but not ground, and it was two cents the pound more; thus showing at once the complicity of the seller. You further say, "Large dealers and small ones almost always *know* regarding the purity of their articles." This may be the case with some of the large dealers; but I know that it is not so with the retailers. But few if any of them are competent, or know how to detect adulterations. But this is not the worst of the matter: but few of them care anything about the quality of the article they sell; if it sells, and customers do not complain, that is all they require. I have offered to show a retailer, doing a large trade in Washington Street, how to detect adulteration of coffee. He did not care to know; customers bought his coffee, and that was enough! I have, within a few months, bought "kerosene" oil, so called, of a grocer. He did not know by whom or where it was made, or professed he did not: it proved worthless, not giving so much light as a tallow candle. Such indifference and ignorance is caused by a mistake as to the duty a retailer owes to his customers. The retailer is paid a profit on his goods by the consumer for the exercise of his skill, judgment and experience in selecting good and pure articles; and, if he is wanting in skill, judgment and experience, he is unfit for his business. Again, you say, "Legislative enactments can never bring about a reform." Here I must disagree with you. Such laws as we have had, I admit, will not; for it has been the case that laws have been made punishing the dealer only for *knowingly* selling an adulterated article. In ninety-nine cases in a hundred, it is impossible to prove the *knowledge* of the seller, though he prepared the factitious article with his own hands. But pass a law imposing a penalty for adulterating, or selling an adulterated article, thus making it the business, as it should be, of the retail and wholesale dealers both to know what they offer for sale, and the evil will be rooted out soon after a few convictions. But I fear no such law can be passed while so many of our legislators are themselves the parties liable to punishment. C. S.

BOSTON, Sept. 1, 1869.

THE AVERAGE WEIGHT AND HEIGHT OF MAN.

Editor Journal Chemistry:

Quetelet, who has devoted more attention to this subject than any other writer, gives the average weight of an adult male 136.993 pounds, and the average height 5.333 feet.

Dr. Gould, who examined a large number of students in the junior and senior classes at Harvard University and Yale College, together with some members of the professional schools, reports their average height 5.666 feet, and average weight 139.700 pounds. A. Maclaven, who has the charge of the gymnasium connected with the Oxford University, England, reports of the first one hundred names on his book, as they arrived at the University, their average height 5.825 feet, and average weight 132.970 pounds.

From the vital statistics of all the members of Amherst College from 1861 to 1869 — making over 600 different students — their average weight was found to be 139.485 pounds, and average height 5.651 feet.

DR. NATHAN ALLEN.

LOWELL, MASS.

GUM FOR LABELS, POSTAGE AND REVENUE STAMPS.— The following recipe is published in a late number of *Dingler's Polytechnic Journal:* Five parts of good glue are to be digested for one day with twenty parts of water, after which nine parts of candy or sugar and three parts of gum arabic (not cherry gum) are dissolved in it. This solution is then ready to be spread upon paper. It keeps well, does not get brittle nor wrinkled, and does not make the sheets stick together when they are piled upon each other. The following is recommended as a good paste for labels for letters, and soda-water bottles: Stir into one pound of a paste of glue and rye-meal one half an ounce of turpentine.

Labels attached with this gum do not get loose in damp cellars. Moreover if, for convenience sake, it is desired to gum these labels preparatory to using them, add one half an ounce of oil varnish and one quarter of an ounce of magnesia to one pound of the former paste, and use it then.

PHYSICAL CULTURE.

Editor Journal of Chemistry:

The first instance in the whole history of modern education where the claims of the body, its proper development and healthy training have been placed, in a large institution, upon the same platform, and the same importance attached to them as to any branch of study or mental acquirement, is found in Amherst College. In 1860, a system of gymnastics was introduced into this institution, which has had wonderful success in developing the physical organization and in improving the health of the students. These exercises were incorporated by the trustees into the regular curriculum of studies, and were made obligatory upon all students to attend upon them as much as on instruction in the mathematics or classics. All gymnasia connected with literary institutions both in Europe and America have failed to accomplish the results intended or expected, because no system of exercises was adopted in harmony with the laws of the body; nor did the character given them correspond to their importance, or to require that daily regular training which was accorded to mental acquisitions. But, at Amherst College, the trustees, instead of leaving the thing to take care of itself, — for students to exercise or not, at their convenience or option, without any guide, system or instruction,— made physical education not only a part of the regular exercises of the institution, compulsory upon all its students, but appointed a professor to this department, — a thoroughly educated physician, — who also has an oversight of the health of all the students. This is the secret of success.

DR. N. ALLEN.

LOWELL, MASS.

GIANT POWDER. — The superiority of giant powder over ordinary black gunpowder for blasting purposes, it is asserted by the California journals, has been proved by actual experiment during the past six months. In the New Almaden mine it was found that to cut a yard of one of the tunnels cost $65 with black and $45.45 with giant powder, showing a saving of 30 per cent. In the Oaks and Reese mine, a hundred feet of drifts, that would have cost $7,500 with black powder, were made under contract for $4,437.50, a saving of 40 per cent; and in the Empire mine it was found, on a long and fair trial, that the extraction of a ton of ore cost $5.39 with the black and $2.09 with giant powder, showing a saving of 61 per cent by the use of the latter.

At another mine it was ascertained that, with giant powder, derricks were no longer needed in the hydraulic claims for lifting large boulders, which can now be shattered at one blast into pieces small enough to be carried down through the sluices. This giant powder is reported to be nitro-glycerine, reduced to dryness by combining it with hydrated silica.

THE ORIGIN OF PETROLEUM. — The origin of combustible volatile and liquid mineral products, such as gas, oil, tar, asphalt, is still an open question. The presence of large beds of anthracite coal lead to the suspicion that oil was derived from the distillation of bituminous coal by volcanic action. Explosions in coal mines indicate that gases can be produced in the beds of coal without the aid of heat; and according as these gases have a vent to escape, or are under heavy pressure, can they remain volatile, or form liquids. Petroleum usually occurs in porous fossiliferous limestones, or in such sandstones as are evidently of marine origin. This has led geologists to look upon petroleum as of animal origin; and recent observations in Egypt have served to sustain this view.

There are in Egypt natural petroleum springs now in actual formation. The coast of this land consists of coral beds. The coral animal grows toward the sea, but dies out on land, leaving a porous lime-rock behind. In the cavities of this rock oil collects which is derived from the decomposition of the polyp coral, and is collected and used by the inhabitants for many purposes. Vast beds of coral would yield a proportionate supply of oil: and this is now considered by many to satisfactorily account for the oil springs and asphaltum lakes of various parts of the world. They were once coral beds of ancient seas, and the oil is of animal origin. — *Journal of Applied Chemistry.*

A Cheap and Durable Stove Polish.—Every housekeeper knows by disagreeable experience the effect of many kinds of stove-polish now in use. Some of these emit an odor when exposed to heat, which is at once very offensive and very unwholesome, while others communicate their color and a great portion of their substance to every object with which they come in contact. An inexpensive article of polish for stoves, grates, fire-places, and iron ornaments, may be easily made by grinding any black, non-combustible pigment with a sufficient quantity of silicate of potash, or "liquid glass," to make it of a proper consistency for application. When the polish has become dry, it will be found to be smooth and shining, wholly without odor, and very durable, while it will not soil the whitest cambric if applied to it. The materials are easily obtained, as easily mixed and applied, and the article should be manufactured in the domestic laboratory, or kitchen of every householder.

Colors for Artificial Flowers.—For blue, sulphate of indigo in solution; for yellow, tincture of tumeric; for red, carmine dissolved in a solution of the carbonate of potash; for lilac, a solution of litmus; for violet, the latter, mixed with blue. When the flowers are made of muslin or paper, they may be dipped in these colors; but, when made of velvet, they should be colored by the finger, dipped in the dye.

Cement for Iron and Stone.—A very durable cement has been in use by parties in Saxony for several years, which is composed of oxide of lead, litharge, and concentrated glycerine. It is said to harden rapidly, and to be unaffected by the ordinary acids, and by heat. The inventor claims that it is less easily broken than stone itself.

Cement for Filling Teeth.—Pulverized borax, one part; freshly calcined oxide of zinc, nine parts; finely powdered silex, two parts; mix them well together, and use like amalgam or any plastic filling.

A Dish of Fruit.—After the refined and complicated luxury of a *recherche* dinner, we seem to go back, when the fruit comes on the table, to the primitive simplicity of the earliest ages. We consume our entrements and our fricassees, our soups and our made dishes; and then our host, as if the repertoire of delicacies had been exhausted, steps out into his garden and his orchard, and brings in a simple dish of fruit; a bunch of golden grapes, some apples, painted red and yellow by the soft pencil of the summer sunbeam, a dusty velvet peach, or some honey-fleshed apricots. He is doing what King Alcinous may have done to Ulysses and the storm-beaten Greeks! it is patriarchal, it smacks of the golden age and the old mythological times; yet it is a custom that does not wither, and will never grow unfashionable. How things alter! The salad, once all that the hermit had to live upon, has become a relish for the gourmand; cheese, once the shepherd's only food, is now an entrement after many courses; fruit, once the only food of the early denizens of the world, is now the mere crowning pleasure of the dinner.

Fruit requires no cooking; the great stationary fire has cooked it to a turn. It has been basted with dew; the soft balmy sun has been its sauce. Its flavor has been mixed by the ministering spirits of garden and orchard; its color and shape are of a lasting fashion; it contains essences never discovered, and wines as yet undreamed of; it is older than the cutlet, and anterior to the fricandeau! its seed blew to us from Eden, or fell to us from the amaranthine gardens. Turtle soup is sublime, and there are ragouts which exercise a moral and psychological influence over the world; but they are earthy. Their component parts are known; there is not the mystery about them that appertains to fruit.

Really to enjoy fruit, one should pick one's own and eat it in appropriate scenery under the tree from which it is gathered, or beside the bush whereon it has grown. The pear reached down from the pliant bough, where it has long swung like a golden weight for Mammon's scales, tastes as much better than the same fruit coldly cut by a silver knife at a formal dessert, as a damson does than its humble, rustic cousin, the sloe; the strawberry has its finest fragrance only when discovered under its own triple leaves. When is the raspberry so delicious as when plucked from the straggling canes? The apple should be twisted from its fostering twig; the grape bunch nipped from the ragged brown branch bound to the green-house roof.—*All the Year Round.*

A New Pharaoh's Serpent.—The sulphuric acid employed to rectify petroleum and tar oil becomes very black. If it be treated with fuming nitric acid a resin separates, which, when cold, is dark brown and brittle. This resin has the property, when burning, of yielding a highly voluminous coal, which expands more remarkably than the sulpho-cyanide of mercury, so popular a few years ago. The resin appears to be the nitrogen product of some acid.—*Journal Applied Chemistry.*

A Good Varnish for Furniture.—Dissolve equal parts of gum copal and essence of rosemary in about three parts of 95 per cent alcohol, heated to 150° F. It should be applied while hot, and, when cool, dries quick and becomes hard and durable.

Agriculture.

RECLAIMING MEADOWS.

Unquestionably the most important and profitable labor in which farmers can engage, after the haying season has passed, is in draining and working over wet meadows in order to fit them for producing the rich upland grasses.

It is a kind of labor which returns the most generous profits of any done upon the farm; and a farmer who has low grounds, and permits them to remain covered with bogs and bushes, is certainly indifferent to his true interest. There is a want of knowledge regarding the subject of reclaiming meadow lands, and, although much has been said and written upon the subject, it is still imperfectly understood what *kind* of lowlands can be profitably worked, and how the labor can be most expeditiously and cheaply performed: these are points about which information is greatly needed. There are different kinds of lowlands or meadows, as well as of uplands; and, before entering upon the work of reclaiming, the nature of the soil or deposits should be investigated, and the facilities of drainage carefully considered. Some meadows are clean *peat-bogs*, others are filled with a silicious deposit intermixed with enough humus to give an intense black hue to the whole. One is made up of light, spongy, and (when dry) combustible organic matter; the other is silicious matter washed from hills. Now, the two varieties of meadow lands require very different treatment, in order to obtain from them the most satisfactory results. The first requires to be worked over with the spade, if too soft to plow, and then the surface must be covered with a heavy coating of pure sand. This, with a slight compost dressing, brings in the timothy and red-top. The second needs turning up to the warm sun and air, and the heavy, cold deposits must be thoroughly pulverized and richly manured with stable manure, or some one of the concentrated fertilizers. This form of lowland is often not profitable to reclaim, and much time and expense has been wasted upon such meadows. The outlet or drainage point in meadows must not be placed too low, as lowland suffers more severely from drought than upland when the natural moisture is wholly withdrawn. Peat, for the first three or four years after it is drained, requires considerable moisture, to enable the chemical decompositions to go forward which fit it for the sustentation of plants.

It has been considered impossible to fit a bog to grow upland grasses if the drainage cannot be carried to a point two feet below its surface. This we have proved to be an error. A bog at Lakeside, bordering upon Lake Kenoza, is so low that we have but *eight inches* above the water level during the spring months. This we reclaimed in part three years ago, and from the portion reclaimed have had most abundant crops of the richest grasses. We are now working over the whole surface of the basin. In some places there is a deposit of peat twelve feet in thickness. Silicious coverings and the application of fertilizers will operate to keep out meadow grasses. On this meadow we have never used an ounce of stable manure, and yet we have cut three tons of hay to the acre. It received, the first year, one ton of fish pomace to the acre, after a thin spread of spent ashes. Lime, ashes, fish pomace, and fine-ground bones are excellent fertilizing agents for reclaimed peat-bogs.

Giving Trees a Dose of Calomel.—A paragraph in a scientific journal came under our notice recently, in which the statement was made, that insects upon trees could be destroyed by boring holes in the trunks, and inserting calomel, or some other salt of mercury. This idea of endeavoring to force into the circulation of a tree powerful mineral poisons, to destroy injurious insects upon the leaves or branches, seems to us very vulgar and absurd. We hope no one of our farmer or horticultural friends will engage in experiments of this nature; for, by so doing, we fear they will greatly injure their fruit-trees. The sap in vegetable structures corresponds, in many of its functions and characteristics, with the blood in animal organizations; and it is well understood among physiologists and surgeons that that fluid is exceedingly sensitive to the presence of foreign agents. No more sudden or effective way can be devised to destroy life than to inject into the circulation any extraneous agent, solid or fluid. Blood will abstract from food or medicine what it requires to healthfully perform its appropriate work, and it can obtain it from no other source; and so with sap: it will draw from the soil the constituent particles it needs, and any attempts to force in abnormal substances, in an abnormal way, can but result in irreparable injury to the structure.

Oats Changing to Rye.—We are often asked if there is any truth in the statements of farmers and others, that oats sown in pastures, and which are fed down by animals during the summer, will spring up the subsequent season in the form of rye. We have never made the experiment, and therefore cannot make any statement based upon personal observation; but we are inclined to think the evidence that the singular change occurs is too strong to be gainsayed. The subject has received the attention of careful observers in this country, in England, and in Germany. Dr. Weissenborn, of the latter country, states positively that this change of species occurs under the conditions named; and many other reliable gentlemen corroborate his statements. It is comparatively but a few years since the various coniferæ have been classified and described; and yet, within that time, some species have entirely disappeared, and their places been taken by others not before known. Our knowledge of the metamorphosis which vegetable structures are capable of undergoing is quite imperfect and unsatisfactory. Upon one of our hill-pastures, which three years ago was covered with white clover, and other sweet grasses peculiar to dry or upland soils, there is now a thick growth of rushes, ferns, and grasses which we have heretofore found only in bogs and lowlands. That which is very singular in regard to this change is the fact that it occurred during one of the *dryest* summers we have experienced for many years. The conditions for a change of species in vegetable growths seemed unfavorable; and yet they occurred.

FERTILITY OF THE SALT LAKE BASIN.

Dr. Prime, Editor of the *N. Y. Observer*, is now in California, having gone thus far, in a journey around the world. His letters to the *Observer* are exceedingly interesting. The following description of the fertility of the Salt Lake Basin, Utah, will be read with interest, and we presume with some degree of astonishment, by our readers. Ninety-three bushels of wheat to the acre is certainly a *very* large yield.

"The vast mountain barrier stretching along the eastern portion of the valley is an immense fountain, streams of the purest water issuing from its sides at every point, and furnishing the means by which this once arid desert has been converted into one of the most fertile plains to be found on the face of the continent. When the Mormons entered this valley, it was like the desolate mountains over which we had passed for hundreds of miles, — a perfect waste of sand and sage bush. Where they got their idea of making it a garden, simply by turning the water upon it, I do not know; but within a little more than twenty years from their first emigration, they have extended a line of farms along the eastern shore of the lake, at least sixty miles in extent, — farms that equal in fertility the finest prairies of the East. We traversed some thirty-five miles of these cultivated fields, and every mile only increased our admiration of the results of this system of utilizing pure mountain water. The most beautiful crops of wheat formed the staple production, — beautiful not alone because they were abundant, but because ripened and harvested, so far as they had been gathered, without a drop of rain, the straw and the ear so bright that they shone like silver in the sun. There was nothing that struck me more forcibly in connection with the standing wheat and the stacks which had been harvested, and the straw as it had been cleaned, than this peculiar brightness. The fields of corn and sorghum were standing up more luxuriant and taller than anything we had seen east of the Mississippi, and equal to anything we had seen in Iowa. The orchards were on every farm, and although not extensive, were loaded with fruit, some of it ripening, but the most in about the same stage as at the East in the same latitude. The road-side for the greater part of the way from Uintah to Salt Lake City was a succession of apple and peach orchards; the fruit, especially the apples, of large size, and the trees literally bending to the ground with their burdens.

WONDERFUL CROPS.

At Salt Lake City, I inquired of Mr. Hooper, the delegate to Congress from Utah, in regard to the actual results of this system of farming, and he stated that there had been produced from a single acre ninety-three bushels of wheat; and I learned from another source that nine hundred bushels had been raised from ten acres. These, of course, were exceptional cases, and were the result of manuring, as well as irrigation, and the most careful cultivation. The seed was planted, rather than sown, and every possible care taken in the cultivation. By the same system of irrigation, Salt Lake City, which had not a tree or shrub when it was first settled by the Mormons, is now one great park of locust and cottonwood trees, the former raised entirely from the seed, and the latter transplanted from the canons in the mountains. Every street has its stream of water, and every garden in the town is regularly watered under the direction of commissioners.

This is certainly a wonderful change for a score of years. One cannot but admire the enterprise which has created a garden out of a vast desert, and in entering the valley at this season of fruits, we could not fail to be struck with surprise at the wonderful results which have been reached; but the amount of labor expended in preparing the soil for cultivation has been small compared with the toil of the early pioneers at the East, who had dreary forests to clear away before they could go to work upon the soil itself. Here the settlers had only to turn the water upon the soil, and the work was almost done."

MARL AS A FERTILIZER.

The most valuable properties of marl consist of phosphoric acid, potash and lime, which it contains in nearly equal proportions. Marl supplies a soil with all the essentials for vegetation with the exception of nitrogen, and this is furnished by clover. A poor, sandy soil requires not only marl, but a substance containing nitrogen.

Some sanguine agriculturists believe that marl will become as valuable for plant food as the coal mines are to commerce. While the one was formed from vegetable life by the action of ages, the other was formed of myriads of minute creatures, in shape and size not unlike a tobacco seed, deposited in immense beds by the action of the ocean. These animalculæ were only a step advanced from vegetable life in their development. These mites of old ocean have left a broad, deep and exhaustless bed of material, as valuable in its way as the stratum of coal in the mountain side. These deposits have a deep-green tinge, and are called green sand-marl. There are three distinct layers, separated by clay deposits, which were probably formed at three epochs. The layers are remarkably uniform, varying but slightly at the top and bottom. The strata themselves are from fifteen to thirty feet thick. In some places the marl is within three or four feet of the surface, so that by removing a slight top layer of sandy loam the bed may be reached; but generally a stratum several feet thick of spurious or useless marl covers the green sand. As a general thing, the lower or older the bed the less phosphate of lime it contains and the more carbonate. In some of the beds are found shells which crumble between the thumb and finger, and recently a shark's tooth was found which belonged to a monster of immense proportions. Usually, however, the beds are uniform in color and appearance, the spade cutting it as easily as a knife passes through a green cheese. The lumps as thrown out, cling together until they become dry, when they crumble and become as fine as an ash-heap. At first marl was sought for the potash it contained; but when analysis subsequently disclosed the fact that it contained phosphoric acid, Professor Mapes and other eminent agriculturists hailed it as an important discovery which would add greatly to the wealth of the country. As a rule, the more nutritious a grain or root the more phosphate it takes to grow it. A field without phosphorus is incapable of growing grain, and no plant suitable for food can be properly cultivated without the co-operation of this substance in some form.

A ton of Peruvian guano, containing four hundred and seventy pounds of the phosphates, costs eighty dollars. The same amount of money will buy eighteen hundred pounds of phosphoric acid, beside as much more of potash, of which there is little in guano.

The use of marl as a fertilizer is now attracting the attention of agriculturists in this section, it having been demonstrated by a practical test that it can be made as active and lasting a fertilizer as the best super-phosphates sold in the markets, and at a cost so trifling as to defy competition. Hon. Benj. T. Biggs, member of Congress from Delaware, a careful and practical farmer, made a trial of ammoniated marl, which had been treated and nitrogenized by a new patented and cheap process, with entire satisfaction.

This process can be put into use without expensive works, and ammoniated marl, equal in value to Coe's, Phillips' or Baugh's best phosphate of lime, can be sold at less than one-fourth the cost to the farmer. — *Phila. Pathfinder.*

Cheering Prospects. — In 1869, says the Charleston *News*, the twelve Cotton States will show more true prosperity than any other section of the world. It estimates the crop of cotton for the present year, which it fixes at 3,000,000 bales. The average number of all crops will amount to $64 per head of the population. And then it states a fact which goes far to account for this gratifying state of things, that "there are now no less than 200,000 whites cultivating cotton with their own hands." Now we do earnestly hope that no one of our subscribers will feel constrained to write to us and say that these statements of the *News* are not true news. We want to believe them, and we do believe them, and they bespeak a glorious future for the South, at least in the line of material prosperity. — *N. Y. Observer.*

The Address at the Cattle Show and Fair of the Franklin County Agricultural Society, held at Greenfield, September 30, was given by the Editor of the Journal.

GERMAN VINEYARDS.

We extract the following from one of a series of articles lately contributed to a New York paper, over the signature of Clark Bell:

My first view of the vineyards of Germany was of those along the river Main, in the vicinity of Frankfort, and thence down its banks to the confluence. The surface of the country is simply undulating, or rolling, and the vineyards cluster everywhere, as well on the slopes and hillsides as on the flat and level land. The vines are planted close together, not quite as closely as in Austria, but much closer than with us, and usually four to five feet apart; and while they are generally trained to single stakes, one to each vine, I observed occasionally a trellis of wood about four feet high, with two slats only, supported by posts firmly driven into the earth. While I frequently observed this trellis, it was after all only of exceptional use, the single stake being of almost universal adoption. The vines themselves, though small as contrasted with Italy or our own country, were of splendid color, of vigorous growth (it was in early August), and were very beautiful. Great attention was paid to the culture, and the vineyards were kept scrupulously clean and neat.

Between Frankfort and Mentz, and a little to the eastward of the latter place, is a small vineyard, which I should not estimate at more than eight acres in extent, but it is the world-renowned vineyard of Hockheimer. This vineyard produces a brand of wine which commands now, and has for a long time, fabulous prices. It is worth almost its weight in hard money. Four thousand plants are here set on each acre. The vines are unusually small, and the product of wine relatively very little indeed. The vintage is late, and the grapes are left hanging until dead-ripe, and the bad and decayed berries picked out carefully. Great care is taken with the pressing; the wine is fermented in large casks, and racked repeatedly before using. The village of Hockheim, near it, is completely surrounded with vineyards. All the trees have been scrupulously cut away, as the German idea is that a tree is injurious to the vine. This village is said to have given the name of Hock to the great mass of German wines.

Along the Rhine itself, from the water's edge to the top of the hillsides, on almost every inch of land that is arable, the vine is planted and grown, and thrives.

In some places I observed divisions on steep hillsides, formed by facing the terrace with a stone wall (as in all countries it is a favorite method of facing the better class of vineyards, especially on very steep declines). Still, as a whole, the hillsides of the Rhine would be classed as vineyards without terraces, and I should estimate that ninety per cent of these vines are trained to single stakes.

The soils of the various parts of this river are as different and as various as the different kinds of wines. Decomposed granite and quartz make good vinelands if in favorable locations. The latter mingled with clay slate is observed in successful vineyards. It is claimed as a matter of experience that marls mixed with pebbles produce the very best wines. Generally any soil will support the vine which is light and dry, if it be also stony or sandy. It is fatal if infected with stagnant water. The vineyardists never take offence at stones in the vineyard. Even large ones are frequently left remaining under the belief that they improve the quality and hasten the maturity of the fruit, but good, strong rich soils never produce good wines. There is no idea more firmly fixed in the German mind, than that the smaller and less luxuriant the plant the better the wine. He has no sympathy with that natural pride which the novitiate vine-grower here feels in the extraordinary growth of his vine, in a single season, which is often measured and treasured and boasted of. Mynheer would only shrug his shoulders and say, "Mein Gott! How can you get good wine from such a green pumpkin vine of a plant?" — *Country Gentleman.*

Value of Spare Minutes. — Madame de Genlis composed several of her charming volumes while waiting in the school-room for the tardy princess to whom she gave daily lessons. Daguesseau, one of the Chancellors of France, wrote an able and bulky work in the successive intervals of waiting for dinner. Elihu Burritt, while earning his living as a blacksmith, learned eighteen languages and twenty-two dialects by simply improving his "odd minutes." A celebrated physician of London translated "Lucretius" while riding in his carriage upon his daily rounds. Dr. Darwin composed nearly all of his works in the same way, writing down his thoughts in a memorandum book which he carried for the purpose. Samuel Smiles says, in his late work, that he personally knew a man who learned Latin and French while carrying messages as errand-boy in the streets of Manchester. Burney, the musical composer, learned French and Latin while riding horseback from one pupil to another. Kirke White also learned Greek while walking to and fro from a lawyer's office.

We find here a clew to the immense amount of labor accomplished by some. Such improve their odd minutes. *Change* of labor is rest, and the *waiting* minutes may usually be filled up with some light occupation of the brain or fingers, which will save much of the annoyance experienced from waiting, and accumulate in time a storehouse of gain.

"Who uses minutes, has hours to use;
Who loses minutes, whole years must lose."

Boston Journal of Chemistry.

BOSTON, OCTOBER 1, 1869.

THE STATE ANALYZATION OF LIQUORS.

There is a large amount of distrust manifested by the intelligent physicians of Massachusetts regarding the purity or integrity of the liquors vended under State authority. As guardians of the public health, and the agents through whom these "medicinal" spirits are to be mainly dispensed, if the intentions of the law are faithfully met, they have not only a right, but it is their *duty*, to inquire regarding the time and care used in the analysis, and also of the competency of the chemist who is appointed to do the work. Without expressing any direct or positive opinions upon these points, we desire to call attention to some of the absurd provisions of the law, and leave our medical readers to form their own views of the probable value of these State analyzations Those sections of the act of 1869 relating to the duties of the State chemist, or "inspector," are as follows:

SECT. 25. The duties of said inspector of liquors shall be to inspect and analyze all liquors of the commissioner, as provided in section three of this act, and also all liquors sent to him by the Constable of the Commonwealth or any of his deputies, under the seal of the agent from whom the said liquors were obtained, as hereinafter provided; keeping a record of the result of his analysis, and reporting the result of such inspection and analysis to the officer from whom the said liquors were received.

SECT. 26. It shall be the duty of the Constable of the Commonwealth, either personally or by deputy, to visit each town and city agent as often as once in every three months, take samples of all liquors kept for sale by the said agent (allowing the said agent to seal the said samples with the seal of his agency), and forward the same to the inspector and assayer of liquors, with a certificate setting forth the kinds of liquors sent, from whom they were obtained, and the date when obtained; and upon the receipt of the report of the inspection and analysis of said liquors, if it shall be found that any of the said samples of liquors were adulterated, to immediately proceed in a prosecution against the said offending agent, as provided in the preceding sections of this act.

By these provisions, the State chemist is required to analyze, during the year, all the liquors purchased by the State agent in Boston, and also all those sent to him by the High Constable, or his deputies. The law *requires* the Constable to visit each town in the State "*as often as once in three months*," and take specimens of all the various kinds of liquors sold by each town agent, and forward them to the chemist for analyzation. Now let us look at the amount of labor which the cruel, but "wise legislators," have heaped upon this unfortunate individual. There are in the Commonwealth about three hundred and fifty towns; and each town is *compelled* to have one or more liquor agents. Each agent must vend at least *ten varieties* of liquor, embracing rum, brandy, gin, whiskey, and the various kinds of wines and malt liquors. Specimens of the liquors of all these agents must be analyzed by the chemist *four* times during the year; therefore there *must be*, according to the simple rules of arithmetic, 14,000 *examinations or analyzations* from this source. The purchases of the State agent, which are to be analyzed, cannot be less than 7,000 packages (probably double this estimate), making, in the aggregate, 21,000 analyzations during the year. In a year there are 313 working days, of 1,440 minutes each, making in all 450,720 minutes. This will give 21½ minutes to each analysis, if the assayer labors every moment of his time, day and night. If, however, the gentleman adopts the "eight-hour system of labor," he will be narrowed down to *five minutes* of time in which to make each "assay." In this estimate of the labors of the chemist, which is perfectly fair and legitimate, no account is taken of the examination of liquors *seized* by the State constables, which he is required to analyze. These specimens must certainly amount to many thousands in number. Five minutes (probably not one) allowed to each analysis! The work should be done by machinery propelled by steam-power. The State pays *fifteen cents* for each analysis, according to the above estimate.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The recent meeting of this Association at Salem was, upon the whole, the most interesting and profitable of any one we have attended during our connection with it, a period of sixteen years. It was interesting and pleasant in its social aspects, as well as important in its business and scientific results. The people of Salem seemed to vie with each other in their efforts to render the stay of the *savans* among them agreeable; and, if any one went away dissatisfied, it must be owing to very unreasonable expectations on the part of the individual.

During the war the meetings of the Association were suspended, and those that have occurred since its close have not been attended by so many of the scientific men of the Southern States as formerly. Some of the most learned and genial members were formerly from the Gulf States, and to them the Association was indebted for useful and important papers. Prof. La Conte, of Georgia, is much missed in the meetings, and there are others we might name who, if living, will, we hope, be present at the Troy meeting. A noticeable feature of the late session was the presence of a large number of young men, and the part they took in the proceedings afforded evidence of diligent and original research in the different fields of scientific inquiry.

The special and emphatic praise bestowed by Profs. Agassiz, Pierce, and Henry, upon the papers of Prof. Morse and the other young men connected with the Peabody Academy of Science, was not only most flattering, but just and well deserved. Prof. Agassiz remarked, on the last day of the meetings, that no papers of greater scientific importance had been presented than those read by the gentlemen referred to, and he hoped they would be printed in full in the Proceedings. The address of the President of the Academy, Wm. C. Endicott, Esq., at the dedication of the museum, on the first day of the meeting, was a model one in its way. The chaste and simple eloquence of the speaker, together with the sound, sensible views advanced, completely enchained the brilliant audience; and, at the close of the address, they signified their satisfaction by a spontaneous and general clapping of hands. The whole of the exercises on Wednesday afternoon were of unusual interest. It was cause of very much regret that the founder of the Academy, Mr. George Peabody, was prevented by illness from participating in the exercises; but he was worthily represented by ex-Governor Clifford, who in an eloquent and effective speech, elicited the warm applause of the audience.

The value of these meetings to students in science can hardly be overestimated; and, although many of the papers read and discussed are regarded by the outside world as abstruse, technical and without practical value, yet this is an erroneous view to take of the matter. All genuine researches in physics or natural science, however abstruse they may be, have a direct or remote bearing upon the great practical events of life, and therefore are of benefit to the world. All new discoveries in science are necessarily for a time recondite, and but partly intelligible even to the discoverers themselves; but ultimately the simple is evoked from the complex, and benefits flow out to the world. How little the world knows regarding the life of these toilers in laboratories, dissecting rooms, libraries and museums! The patient, protracted, exhausting labors, in daylight and darkness, the racking of the brain, the draughts upon the ingenuity, the mistakes, the errors, the disappointments, — who can know of these but the toilers themselves? And yet it was only necessary to cast the eye over the members, in session at Salem, to learn that great intellectual labor is not antagonistic to health. Profs. Agassiz, Henry, Silliman, T. Sterry Hunt, O. C. Marsh, Horsford, Wurtz, Joy, Gould, and a score of others, whose rubicund countenances and rotund forms were everywhere present, would seem almost to prove that robust health is an attendant upon severe, exacting scientific labor. Hard brain-work does not necessarily kill people, or impair health. It is care, fret, anxiety, that causes sad inroads upon the system, especially when they come in connection with severe mental exertion.

A VALUABLE LINIMENT. — A liniment which we have found most serviceable in the family and in the stable is prepared as follows:

℞ Alcohol (95 per cent), 1 quart.
Fluid extract of arnica, 4 fluid ounces.
Camphor, 2 fluid ounces.
Stronger aquaammonia, 1 fluid ounce.
Tinct. opium, 1 fluid ounce.
Water, 1 quart.

Add to the alcohol the arnica, camphor, ammonia, and tincture of opium; and, after the camphor is dissolved, the water may be added. This liniment may be applied for the relief of sprains, bruises, rheumatic and neuralgic pains, etc., with decided advantage. For use in the cow and horse stable, it will be found most efficient. It can be furnished by druggists at about one dollar the quart, and is much to be preferred to the expensive liniments which are so freely sold in the shops.

THE INHALATION OF CARBONIC ACID.—The old idea, that carbonic acid is in itself a *poison*, still prevails to a considerable extent, even among well-informed people. Carbonic acid exerts no more corrosive or poisonous influence upon the system than water. Water deprives persons of life, when they are immersed in it, by excluding oxygen from the respiratory organs; and this is why fatal effects are obtained from carbonic acid. Carbonic oxide (CO), when inhaled, is poisonous; it acts upon tissues, produces chemical changes in the blood, and arrests respiration. Not so carbonic acid: we can *drown* in it; but it is in no sense a *poison*. From laboratory experiments in inhaling carbonic acid, we are led to think that possibly it may be found to possess valuable therapeutic properties, when its nature is fully understood. The asphyxia which it produces, although apparently painful and injurious, or attended with fatal consequences, is probably not so. A technical laboratory may be said to be never free from the gas; and the only influence it exerts upon workmen is of a somnolent nature. Breathed in small quantities, mixed with air, it causes a sleepy feeling, unattended with headache. In the manufacture of nitrate of ammonia from the carbonate in a large way, vast quantities of the gas are liberated; and we have seen mice, in attempting to run across the laboratory floor, tumble over, and remain asphyxiated for a long time, and then, upon a subsidence of the flow of gas, recover, and scamper away as if nothing had happened. The dog, which so many of our readers have seen thrust into the celebrated cave, *Grotto del Cane*, near Naples, evidently suffers but very little; and, although made perfectly insensible many times in a day, is not apparently injured in health. These examples, when taken in connection with other significant facts, incline us to think that a series of carefully conducted experiments in the employment of certain quantities of carbonic acid, diluted with air, may lead to the discovery of a peculiar anæsthetic, or sleep-producing agent, of a simple and desirable nature. If the pressure of exacting duties permits, we intend to institute a series of experiments of the nature indicated, at no distant day; and our readers will know of the results.

THE USE OF PHOSPHATES IN BREAD-MAKING.—It is quite amusing to read, in the English scientific and popular journals, accounts of a *very recent* discovery of Prof. Liebig, in which he recommends phosphoric acid as a substitute for bi-tartrate of potassa, and tartaric acid, in bread-making. This application of phosphoric acid is not very *new* in this country, Prof. Horsford, of Cambridge, having suggested it a long while ago. It is as many as *sixteen years* since the professor placed in our hands, for trial in the family, a parcel of granular phosphoric acid, combined with bi-carb. of soda, designed as a bread-raising powder. This parcel was the result of his very first experiment; and we found it to produce most excellent, and, we believed, healthful bread. The chemical changes which result when this mixture is combined with dough, and submitted to the action of moisture and heat, are very easily understood. Carbonic acid is liberated by the decomposition of the soda carbonate; this gas lifts and expands the dough; and, by the union of the acid with the soda, phosphate of soda is formed, and remains in the loaf. This phosphatic salt is a normal constituent of the blood and tissues, and therefore cannot but be healthful in its influence. We have always regarded the idea or discovery as highly creditable to Prof. Horsford; and there is great injustice done him in coupling the name of Liebig with it.

ALUM REMEDY FOR CHRONIC DIARRHŒA.—Dr. Russell, of Grand Rapids, Mich., writes us as follows: "Having suffered from drinking Cochituate water through a lead pipe in my office in Boston, causing partial paralysis of the rectum and diarrhœa for twelve months, I was induced to use the following prescription, given me by Prof. Geo. B. Wood, Philadelphia, with the happiest results:

Pulv. alum, gra. X.
" nutmeg, gra. V.

This powder to be taken three times a day.

Since my recovery, the prescription has been used in cases caused by lead-poison, and others of chronic diarrhœa, with uniformly good results.

THE MECHANICS' FAIR.—This association held its tri-yearly fair in this city in September, and a very satisfactory exhibition was made of the mechanical and industrial products of New England. It may be regarded as one of the largest and most complete exhibitions ever made by the association, and the large halls were thronged with visitors during its continuance. No exhibitions in the country are more worthy of the attention of manufacturers, inventors, etc., than those of the Massachusetts Charitable Mechanic Association.

☞ Very many of our subscribers, residing in the Western and Southern States, will find upon their *Journals* the little yellow slip upon which the name is printed, and the date to which subscription moneys are paid. We desire to have the names and place of residence of all our subscribers perfectly correct; and therefore, if there is any error in spelling or direction, in any case, please inform the office at once, that it may be corrected. It will take our printer another month to get the entire list into type, so many are the names of our patrons.

SPOTS ON THE SUN.—From the first to the third of September, the sun was almost wholly free from spots; but on the fourth they reappeared, and as many as five were distinctly counted. Two of them were of immense size, and appeared in the form of elongated cones, with numerous protuberances. The large and small spots together at one time covered more than one-fifth of the sun's diameter. During the entire summer, there have been but few days when patches of opaque matter have not been observable in the sun's photosphere. There can be no question but what these spots exert a very great influence upon our planet, and produce meteorological and electrical changes of stupendous magnitude.

THE ATLANTIC CABLE OF 1866.—Some two months since a fault was discovered in this cable, which has not yet, we believe, been repaired. It is not of a nature so serious as to interrupt communications, but still it is very troublesome, and must be found and put in order. Four interruptions have occurred in this cable, while in the one of 1865, so many months lost on the bed of the ocean, not a single one has occurred. It is probable that deep-sea cables will continue to improve in insulation as they grow older; and hence, unless some unforeseen casualty occurs, the property will continue to grow more valuable.

☞ WE venture to express the opinion that this journal has, at the present time, the largest circulation of any journal of its class in the world.

HAY CATARRH.—A gentleman in Illinois writes us that he has been a great sufferer from hay catarrh for several years, and that he has found relief in the free use of very finely powdered *catechu*. He snuffs it up the nostrils several times in the day. By the use of catechu, he states that a speedy and permanent cure is effected. This substance is very cheap, and is found in the shops in the form of hard, gummy masses, easily pulverizable. It holds a large amount of tannin, and therefore has very astringent properties. It is worth a trial, as it can do no harm.

☞ THE beautiful new type in which this number of the *Journal* appears gives it an exceeding neat and comely appearance. Every number is stereotyped, and consequently from the plates we can supply copies of the back numbers of this volume to any extent desired.

BOOK NOTICES.

A GENERAL TREATISE ON THE MANUFACTURE OF SOAP; Theoretical and Practical, comprising the Chemistry of the Art, a Description of all the Raw Materials and their uses. By Prof. H. DUSSAUCE, lately of the laboratories of the French Government, etc. Philadelphia: Henry Carey Baird. 1869.

The manufacture of soap is a great industry in this and all other countries. To every class of society, from the highest to the lowest, soap is an absolute necessity. The measure of the civilization of a people is afforded from a knowledge of the amount of soap consumed by any nation. A full, complete and clear treatise upon soap-making has long been needed, and we are glad that its preparation fell into the able hands of the late Professor Dussauce. This treatise may be regarded as an exhaustive one, as all that is known of the arts and chemical processes involved in the manufacture of soap are here placed before the reader. To soap-makers it is an indispensable treatise, and the general reader will find in its pages a vast amount of interesting and valuable information. The compiler, Dr. D., was an indefatigable worker in the various departments of industrial science; and the present volume is the last of many treatises prepared by him, his death having occurred in June last.

A NEW ELEMENTARY COURSE IN THE GERMAN LANGUAGE, for the Use of Schools. By GABRIEL CAMPBELL, M. A., Professor in the State University of Minnesota. Third Edition. Boston: Woolworth, Ainsworth & Co.

The German language does not receive that attention in our schools which its great importance demands. The culture of the age requires an acquaintance with the science and literature of Germany; and better would it be for the youth of our country if a portion of the time which they are required to spend in the study of Latin and Greek were devoted to modern languages, especially the German. This school-book is a very excellent elementary work, and one which in method, arrangement, and clearness of illustration has hardly been surpassed.

Medicine and Pharmacy.

PAU AS A HEALTH-RESORT.

Dr. J. Whipple, of this city, communicates to the *Medical and Surgical Journal* some statements respecting the old French town of Pau as a winter resort for invalids. Dr. W. has resided there for several winters, he being an invalid, and his statements are worthy of entire confidence. He contemplates returning to France, and will act as consulting physician to any American invalids who may need his services. Dr. W. writes with great good-sense, and with that caution and moderation which inspires confidence in what he says.

Pau is in the extreme south of France, and is accessible from all points by rail. It is distant seventeen hours from Paris, and twenty-two from Marseilles. It

has a population of 20,000. The situation of the town is very beautiful, and possesses many attractions, natural and artificial. Dr. Whipple says:

"The place has been for thirty years much frequented by English, and later by our own countrymen, and the Anglo-Saxon race is famous for carrying along with it its customary comforts and for establishing a regular source of supply when it becomes stationary. So in Pau, comfortable, besides well-furnished apartments and hotels, and *maisons garnies* second to none in Europe, are excellent markets and good grocers provided with English and American articles, obtainable almost nowhere else on the continent except in Paris. Good servants and particularly good cooks are to be had for moderate wages, and very fair horses and excellent carriages at extremely moderate rates; though, if any one is ambitious of great excellence or elegance in his mount or equipage, he must import them. The expense of living at Pau need not be great. Viewed after our extravagant American standard, it is a very cheap place. I should say one might live in perfect comfort on two-thirds what it would cost to live in a corresponding style at Paris.

"There are three English and one Scotch Presbyterian churches, all organized within several years. There is a comfortable English club in a commodious club-house (built 1869), with good restaurant, an excellent and quite extensive library, and a large file of newspapers of all nations. This is easy of access to all visitors. There is a very pretty new theatre, where there are through the season dramatic and operatic performances, though it must be confessed that they are less famous than those at the Comedie Françaises and the Grand Opera.

"Pau is freer from the appearance of a place of resort for invalids than any place I know, when there are so many who really seek it for sanitary reasons. The attractions of the place for the general visitor are so numerous that the proportion of invalids is largely reduced, and the place itself is so cheerful in its aspect, and so much that is gay and lively is going on throughout the season, that one soon forgets the pale and sickly look of the poor fellow he has just passed.

. . . .

"Now for what many will regard as the most important point of all, — the climate of Pau. If we take the word of some who have written about it, it is the climate we may expect to find in Paradise. If we listen to some one who has spent a rainy week there only, looking in vain from the Castle Terrace or the Place Royale for the white peaks of the mountains which he is told lie just over the river, and seeing Pau only from its muddy streets or his hotel window, we shall wonder that any one ever left the shadow of the State House to encounter the wretched climate and dull stupidity of Pau. *Medio tutissimus ibis.* One will have to go farther than Pau to find a perfect climate, and one might go very far, too, and find no better. During the season of 1866–7 there were but seven days of what any one could call cold weather. About the middle of January came a fall of snow, perhaps six inches, — very unusual for Pau, — and for nearly a week the ground was slightly frozen every night. That was all the winter we had. The rest of the season, even invalids scarcely had need of a top-coat.

. . . .

"There is always a good deal of rain; but, in spite of it, the place is not damp. The situation of the town and the nature of the soil is such that the water very soon leaves the surface, and there is nowhere about the town any standing water. I used to find that my tobacco, left open in a room where the sun never shone, got so dry at the end of a few days that I could not smoke it. Even when it does rain, it is rare that an invalid, properly protected, cannot keep out of doors; for the air is almost invariably milder during a fall of rain than on the bright days. When the sun does shine, the brightness of the day makes one forget that he has ever seen any other weather. There is an indescribable charm in a sunny winter day at Pau which I have never seen equalled elsewhere.

"About the city there is ordinarily almost no wind, and it is extremely rare — not more than three or four times in a season — that the wind is strong enough to be disagreeable to the most sensitive throat or lungs.

"Those who are forced to seek a warm climate — especially if they have been accustomed to the changes of a New England winter and spring — are apt to expect of the climate to which they are sent all that is wanting in that they have left, and often fail to derive the fullest advantage from the change by refusing to see that in all climates certain precautions are necessary, and that none are without disadvantages. So I have often heard it said, "Pau is subject to as sudden and as great changes of temperature as Boston." Hardly as sudden, and certainly by no means as great. Yet there are sudden changes, which will certainly prove detrimental if ignored. For instance, on a bright day there is a very perceptible difference between the sunny and the shady sides of the street. There is always a great change of temperature just at sunset. For half an hour before and as long after sunset, the strongest peasant will wrap himself in his frieze cloak, which he always has at hand. Later in the evening the peculiar chill of the sunset hour vanishes entirely. But these are changes which can be guarded against, and that most easily. I have been often surprised to find a most singular and unaccountable obstinacy against taking proper precautions, because, as I have heard remarked, "if I have got to take precautions, I might just as well have staid at home." I have never seen a sudden change of temperature in Pau which could not be perfectly easily remedied by buttoning or unbuttoning a moderately thick coat. And here I may mention something worthy to be borne in mind. Such clothing should be worn as can be easily adjusted to suit these changes.

"As I have already said, there is a great deal of rain at Pau; and if one is opposed to carrying an umbrella, or to wearing thick boots, let him keep away from the neighborhood of the Pyrenees. But, fortified with these, there are few days when one cannot keep out very comfortably. There are days when the air seems rather chilly and cold, and one is very apt to complain of this until he remembers that the brightness of the preceding day may make the contrast more striking, and, on consulting the thermometer, he finds to his surprise that it indicates a degree of cold which would not trouble him if he had not expected something more nearly approaching perfection in a place of sanitary resort.

"The season for Pau is from October until May or June. Strangers ought not to go much earlier than October, and it is hardly safe to leave before May. Many lose the whole advantage gained during the winter by going north before the warm season is sufficiently advanced. Not only do they lose the benefit of their winter visit, but they lose the most beautiful season for Pau and its most charming environs.

"I think these recommendations may certainly be claimed for it, viz: accessibility by easy conveyance, a large degree of general comfort, healthy diversion and cheerful surroundings for well or ill, and a climate sufficiently mild to admit of out-of-door life to a great degree. These are not very frequently united in one place. If one has already found a climate which suits well his individual case, I would certainly not advise him to change it for that of Pau; nor to go there at all, if he is prejudiced against the place. In such case he would probably only see the disadvantages of the place — which are not lacking — and would certainly fail to derive the expected advantage from his residence there. I am firmly of the belief that climate, aside from other influences, will prove ineffectual in arresting and curing disease."

Dr. E. B. Shedd, in the *British Medical Journal*, recommends the following treatment for typhoid fever: "As soon as there is abdominal tenderness, give drachm doses of glycerine three times daily." This, he says, acts wonderfully well, causing a speedy abatement of all the symptoms.

Mr. Wilcox, late House-surgeon of King's College Hospital, recommends the use of the sulphates in chronic cystitis, where the urine decomposes before it is eliminated. By the employment of the sulphate of soda, all putridity disappears, and the urine becomes clear and colorless.

Quarrels Among Doctors. — The September number of the *Nashville Medical and Surgical Journal* comes to us freighted with a heavy load of what may be called private griefs. Very nearly the entire number is taken up by Dr. Bell and Dr. Bowling, the editors, in statements and charges relating to matters concerning which they are at variance with Dr. Gaillard, editor of the *Richmond and Louisville Medical Journal.* The public take but little interest in quarrels. What appears, for the time being, a very grave matter to the combatants, is of the least possible consequence to the great outside world. Regarding the merits of the controversy, or quarrel, between these gentlemen of high respectability, in Nashville and Louisville, we profess to have but little knowledge. We seldom or never engage in quarrels; and, although frequently subjected to injustice and wrong, we endeavor to look at the matter from the most charitable standpoint, and, if punishment of our enemy seems necessary, we find it most effectually accomplished by some act of kindness, extended to him when opportunity occurs. The gentlemen have manifestly wrought themselves up into a state of abnormal excitement, and in their statements and rejoinders use epithets, and make personal flings, which do not form pleasant reading to disinterested parties. We hope the matter will now be allowed to drop, and hereafter all will be quiet south and west of the Potomac.

A Simple Remedy for Whooping-Cough. — Dr. Howard Sargent, of this city, writes us a note, saying that for eight or ten years past he has used, as a remedy for whooping-cough, a tea made from red-clover blossoms He remarks: "It is so simple that many would not give it a second thought. I can say with truth that I never knew it fail. I generally expect a cure in ten days. Four years ago I had children in three families sick at the same time: they were all well in ten, twelve, or fourteen days. There is some care and art necessary in making the tea. I select and cure the blossoms myself, and take of the best blossoms about ℥ji to a pint of boiling water, steep for four hours, and give a wineglassful occasionally during the day. Should it operate on the bowels, no harm is done; the dose, in that case, may be diminished. I ask physicians to try it before they reject it. I sometimes add a little honey to make it more palatable."

FOR TOOTHACHE.

EXTRACTUM GALLÆ COMPOSITUM.

℞ Gallæ pulv., No. 40, four troyounces.
Pyrethri rad. pulv., No. 40, three troyounces.
Opii pulveris, half a troyounce.
Glycerinæ, a troyounce.
Alcoholis Diluti, a sufficient quantity.

Mix the powders, moisten the mixture with three fluidounces of the diluted alcohol mixed with the glycerin, and pack in a conical percolator. Then pour on diluted alcohol until a pint of tincture has passed. Evaporate on a water bath to a soft extract and preserve it for use.

This extract has been used for thirty years as an application to painful decaying teeth where the nerve pulp is sufficiently accessible to bring the extract into contact with it. The glycerin has been added more recently to prevent the extract from becoming friable. A solution in which these quantities are present in a pint, odorized with oil of gaultheria, makes a good liquid preparation, applied on cotton. The soft extract is applied by inserting a pellet in the cavity and then a wad of cotton, advising the patient to reject the saliva which freely flows from the action of the pyrethrum on the salivary glands.

Ointment for Hæmorrhoids, by the late Prof. W. R. Fisher.

Take of Sulphate of Morphia,	three grains.
Extract of Stramonium,	thirty "
Olive Oil,	sixty "
Carbonate of Lead,	sixty "
Lard Cerate,	three drachms.

Rub the extract, if not uniformly soft, with a few drops of water; add the powders and olive oil, and rub till perfectly smooth, and then incorporate them with the cerate.— *American Journal of Pharmacy.*

ANCIENT MEDICAL SCIENCE.

The greatest name in medical science, in ancient or in modern times, — the man who did the most to advance it; the greatest medical genius of whom we have record, — is Hippocrates, born on the island of Cos, B. C. 460, of the great Æsculapian family, and was instructed by his father. We know scarcely more of his life than we do of Homer himself, although he lived in the period of the highest splendor of Athens. And his writings, like those of Homer, are thought by some to be the work of different men. They were translated into Arabic, and were no slight means of giving an impulse to the Saracenic schools of the Middle Ages in that science in which the Saracens especially excelled. The Hippocratic collection consists of more than sixty works, which were held in the highest estimation by the ancient physicians. Hippocrates introduced a new era in medicine, which, before his time, had been monopolized by the priests. He carried out a system of severe induction from the observation of facts, and is as truly the creator of the inductive method as Bacon himself. He abhorred theories which could not be established by facts. He was always open to conviction, and candidly confessed his mistakes. He was conscientious in the practice of his profession, and valued the success of his art more than silver and gold. The Athenians revered him for his benevolence as well as genius. The great principle of his practice was trust in nature; hence he was accused of allowing his patients to die. But this principle has many advocates among scientific men in our day; and some suppose the whole philosophy of homœopathy rests on the primal principle which Hippocrates advanced. He had great skill in diagnosis, by which medical genius is most severely tested. His practice was cautious and timid in contrast with that of his contemporaries. He is the author of the celebrated maxim, "Life is short and art is long." He divides the causes of disease into two principal classes; the one comprehending the influence of seasons, climates, and other external forces; the other, from the effects of food and exercise. To the influence of climate he attributes the conformation of the body and the disposition of the mind. He also attributes all sorts of disorders to a vicious system of diet. For more than twenty centuries his pathology was the foundation of all the medical sects. He was well acquainted with the medicinal properties of drugs, and was the first to assign three periods to the course of a malady. He knew, of course, but little of surgery, although he was in the habit of bleeding, and often employed his knife. He was also acquainted with cupping, and used violent purgatives. He was not aware of the importance of the pulse, and confounded the veins with the arteries. He wrote in the Ionic dialect; and some of his works have gone through three hundred editions, so highly have they been valued. His authority passed away, like that of Aristotle, on the revival of European science. Yet who have been greater ornaments and lights than these distinguished Greeks?

The school of Alexandria produced eminent physicians as well as mathematicians, after the glory of Greece had departed. So highly was it esteemed, that Galen went there to study five hundred years after its foundation. It was distinguished for inquiries into scientific anatomy and physiology, for which Aristotle had prepared the way. He was the Humboldt of his day, and gave great attention to physics. In eight books he developed the general principles of natural science known to the Greeks. On the basis of the Aristotelian researches, the Alexandrian physicians carried out extensive inquiries in physiology. Herophilus discovered the fundamental principles of neurology, and advanced the anatomy of the brain and spinal cord.

Although the Romans had but little sympathy for science or philosophy, being essentially political and warlike in their turn of mind, yet, when they had conquered the world, and had turned their attention to arts, medicine received great attention. The first physicians were Greek slaves. Of these was Asclepiades, who enjoyed the friendship of Cicero. It is from him that the popular medical theories as to the "pores" have descended. He was the inventor of the shower-bath. Celsus wrote a work on medicine which takes almost equal rank with the Hippocratic writings. Medical science at Rome culminated in Galen, as it did at Athens in Hippocrates. He was patronized by Marcus Aurelius, and availed himself of all the knowledge of preceding naturalists and physicians. He was born at Pergamus, about the year A. D. 165, where he learned, under able masters, anatomy, pathology, and therapeutics. He finished his studies at Alexandria, and came to Rome at the invitation of the emperor. Like his patron, he was one of the brightest ornaments of the heathen world, and one of the most learned and accomplished men of any age. "*Medicorum dissertissimus atque doctissimus.*"* He left five hundred treatises, most of them relating to some branch of medical science, which give him the merit of being one of the most voluminous of authors. His celebrity is founded chiefly on his anatomical and physiological works. He was familiar with practical anatomy, deriving his knowledge from dissection. His observations about health are practical and useful. He lays great stress on gymnastic exercises, and recommends the pleasure of the chase, the cold bath in hot weather, hot baths to old people, the use of wine, three meals a day, and pork as the best of animal food. The great principles of his practice were, that disease is to be overcome by that which is contrary to the disease itself; and that nature is to be preserved by that which has relation with nature. As disease cannot be overcome so long as its cause exists, that, if possible, was first to be removed, and the strength of the patient is to be considered before the treatment is proceeded with. His "Commentaries on Hippocrates" served as a treasure of medical criticism, from which succeeding annotators borrowed. No one ever set before the medical profession a higher standard than Galen, and few have more nearly approached it. He did not attach himself to any particular school, but studied the doctrines of each — an eclectic in the fullest sense. The works of Galen constituted the last production of ancient Roman medicine; and, from his day, the decline in medical science was rapid, until it was revived among the Arabs. — *Dr. Lord's Old Roman World.*

* St Jerome, *Comment. in Aoms*, c. 5, vol. vi.

Telegraphing Pulse-beats and Heart-throbs. — At the session of the American Association for the Advancement of Science, at Lyceum Hall, Salem, Mass., Friday evening, Dr. Upham announced that a telegraphic wire connecting New York, New Haven, Boston and Salem, had been generously devoted to the use of the Association for the evening, and that arrangements had been made to attempt the experiment of telegraphing from the City Hospital, Boston, the movement in the heart and pulse of a variety of subjects, both in normal and abnormal condition, which should be observed simultaneously in the four cities. The telegraphic instruments were connected with the wire, the physicians in attendance at the City Hospital, Boston, answered "Ready." Mr. Farmer arranged the electro-magnetic recording apparatus, lighted the magnesium lamp, (the gas lights being turned down), throwing a beam of light on the little mirror attached to it, and which was thus reflected as a spot of brilliant light upon the wall, visible to the whole audience. In a moment connection was made with the pulse of a healthy subject in Boston, and sixteen miles away. Presto! the spot of light vibrates up and down, up and down on the wall; we see the motion in Salem; the audience counts sixty to the minute. Next the wire is connected with the wrists of an excitable young disciple of Æsculapius, and we are amused to see the spot of light vibrate up to ninety. The next case was that of the movements of the heart of a patient with chronic pneumonia, followed by one having organic malformation of the heart. In both these cases the irregular action was, of course, accurately indicated.

We were informed from the hospital that the nervous gentleman had consented, for the sake of science, to give an exhibition in his own person of the effects of *veratrum viridi* in reducing the action of the heart.

The drug was taking effect; the connections are made, and the beam of light beats to the slower time of sixty-four instead of ninety. A few minutes later it declined to forty-eight, which, considering the peculiarities of the individual, was startling.

At the close of this interesting session, Dr. Groux telegraphed the motion of his own heart to Boston, New Haven and New York, from which reports will be doubtless made by the accomplished observers stationed at those points. — *Telegrapher.*

For tapeworm, the following method seldom fails, if the child is strong enough to bear the necessary fasting: In the evening a dose of *castor-oil* must be given; the following morning, after the bowels have been relieved by the aperient, the oil of male fern is to be given in the following draught:

℞ Olei felicis mas., ʒ jss.
Syrupi.
Mucilag. acaciæ, aa ℥ ss.
Aq. cinnamoni, ʒ j. M

ft. haustus.

After three hours, this draught must be followed up by a second dose of castor-oil.

Cure for Warts. — Warts may be readily cured by cutting a hole in a piece of sticking plaster, the size of the wart, applying the sticking plaster so that the wart protrudes, and then using —

℞ Caustic potash, ℥ ij.
Gum arabic, ℥ ss.
Flour sufficient.

M. — Make a paste.

S. — To be left on for a few hours.

Dr. W. Marshall recommends, in the *Glasgow Medical Journal*, the union of chloroform and opium for the relief of pain. From ten to twenty drops of chloroform are combined with from ten to forty drops of Batley's Sedative, and given at one dose. This generally gives relief, and induces sleep.

TREATMENT FOR PIN WORMS.

Editor Journal of Chemistry :

Several weeks since, I noticed in your valuable *Journal* the use of lard as a cure for pin-worms. A few days after I saw that notice, an elderly man, whom I had formerly treated for that troublesome difficulty with lime-water injections, etc., called upon me again with the same complaint. The idea occurred to me, that, if fatty matter alone would procure relief, the well-known benefit of mercurial ointment in cases of itch would afford a better probability of success than simple lard. I therefore directed equal parts of mercurial unguent and lard to be used after each evacuation, and at night on going to bed, and also to pass a portion of the ointment within the sphincture. The patient has been completely relieved, or cured, by this application.

Respectfully yours,
Joseph White, M. D.

Canajoharie, N. Y., August 2, 1869.

☞ With all the care exercised in correcting typographical errors, some very provoking ones will occasionally occur. In the formula for Dr. Hill's new myrrh mixture, published in the last *Journal*, the scruple sign (℈) was used for O, pints.

The corrected formula is as follows:

MIXTURE OF MYRRH AND PYROPHOSPHATE OF IRON.

℞. Gum myrrh Turkey,
Pyrophos. iron, āā. ℥ij.
Sugar, ℥v.
Tinct. ol. gaultheria, ʒx.
Brandy, Oss.
Aqua, Oiij ss.
Carb. magnesia, ℥j.

Dr. J. Waring Curran recommends the iodide of ammonium in diseases of the glandular system. The following are his prescriptions in Goitre:

℞ Ammonii iodidi, gr. xv.
Spiritus chloroformi, ʒ ij.
Aquæ camphoræ, ad ℥ viij. M

S.— ℥ j ter in die.

℞ Ammonii iodidi, ʒ ij.
Glycirine, ʒ ij.
Adipis benzoat, ℥ jss. M.

ft. unguent.

Dr. Smith, in "Wasting Diseases of Children," recommends the following vermifuge mixtures:

℞ Santonini, gr. xv.
Pulv. zingib., gr. v.
Pulv. jalapæ, ʒ ss.
Sulphuris loti, ℥ j. M

ft. confect.

S. — A teaspoonful two or three times a day; for the *lumbricus* and the *tricocephalus dispar.*

Dr. Boulou has devised the following plaster for rheumatic and neuralgic pains:

℞. Empl. plumbi, ℥ xvj.
Ext. pini sylvestris.
Ext. Belladonna, aa ℥ jss.

Spread evenly over fine strong linen, so that every square inch should contain two grains of the active ingredient. — *Medical Archives.*

The following plan has been repeatedly used with success in strangulated hernia: Place the patient in most convenient position for taxis, inject hypodermically, immediately over point of obstruction, twelve drops of Magendie's solution of morphia; cover the patient's face with a towel, and pour over the tumor, from a considerable elevation, a bucket of very cold water; push the bowel back before the shock is recovered from. This plan will frequently succeed when all others have failed.

Japanese Dentistry.—They have dentists in Japan, who evidently do not enjoy the benefits of dental associations and journals. The Japanese are a remarkable people ; their jugglers are unsurpassed ; but commend us not to their dentists. Their manner of extracting a tooth must be tempting to their patients, and reminds one of the method of removing a rusty screw. The tooth is tapped with a mallet, until it can be extracted with the fingers ; pleasantly suggestive of an amount of malleting which we should think would not commend Japanese dentistry.—*Medical and Surgical Reporter.*

CASTOR OIL AND GLYCERIN POMATUM.

A correspondent says: "You would oblige the pharmaceutists of Philadelphia by giving a formula for castor oil and glycerin pomade, so that every one can make it, in your next number."

The Editor is disposed to comply with this request, though he thinks there are many of his readers who have recipes as good, or perhaps better than the one he now communicates:

CASTOR OIL AND GLYCERIN POMATUM.

Take of White Wax, an ounce and a half,
Glycerin, pure, two fluidounces,
Castor Oil, twelve ounces,
Oil of Lemon, five drachms,
Oil of Bergamot, two drachms,
Oil of Lavender, one drachm,
Oil of Cloves, ten drops,
Annatto, ten grains,
Alcohol and Water, a sufficient quantity.

By a moderate heat, dissolve the wax in a small portion of the castor oil (one-fourth), and triturate it with the remainder of the oil and the glycerin till it is quite cool; then add volatile oils. Lastly, rub the annatto with a drachm of water till smoothly suspended, add a drachm of alcohol, and stir the coloring into the pomade until it is thoroughly mixed.

It is quite necessary to use the blandest castor oil, and to heat it as little as possible, to avoid the ricinic odor which excessive heat develops in castor oil.—*Prof. Proctor in American Journal of Pharmacy.*

CINCHO-QUININE.

Messrs. J. R. Nichols & Co.

I have used in my practice this summer forty-five ounces of cincho-quinine, and its use has afforded me entire satisfaction. I have found it in intermittents as reliable as the sulphate of quinine; and the advantages which have been claimed for it over that salt are just in every respect. A. C. JACKSON, M. D.

GOSHEN, Ind.

I have used the cincho-quinine in several important cases, and carefully noted its effects. I am satisfied it is fully equal to the sulphate, and, in many respects, superior to any quinine I have ever used in a practice of twenty-two years. J. L. HARRIS, M. D.

CAZENOVIA, N. Y.

I have for some time intended to present to you the results of my trials of cincho-quinine. Circumstances have prevented me from doing so at an earlier date. I take pleasure in saying that the article has been used with much satisfaction by me, and, if I can obtain a supply, shall always use it in place of the sulphate. Its taste being far less bitter and disagreeable is a great point. Unlike sulphate of quinine, when used for a considerable time in full doses, it does not produce headache, perversion of sight and sound, and other disagreeable symptoms. I would recommend the profession everywhere to make trial of cincho-quinine.

P. A. MARK, M. D.

QUINCY, Ill.

COD-LIVER OIL, WITH HYPOPHOSPHITES OF LIME AND SODA.—We have received from George F. Fort, M.D., ex-Governor of New Jersey, and one of the most distinguished physicians in the country, the following statement respecting the effects of the cod-liver oil with hypophosphites of lime and soda. He says:

"I procured of you, last spring, a supply of Cod Liver Oil with hypophosphites of lime and soda, which I desired to use in the case of a young lady troubled with a cough of long standing. I feared serious pulmonary trouble, she having lost a sister, of phthisis. Shortly after commencing with the oil, she began to improve; and she continued taking it ten weeks, at the end of which time she was *perfectly relieved.* It is certainly a valuable remedy or combination, and, if accessible to the medical gentlemen in this section, would be largely employed."

For the convenience of small dealers, we present below prices of our chemical products, in small quantities, such as are often wanted. For prices in packages, or in large quantities, see our regular monthly Price-List.

PRICES OF VIALS AND BOTTLES.—g.s.v., means glass-stoppered vial, the price of which is 10 cents, more or less; c.v., corked vial, 6 cents, more or less; c.b., corked bottle, 12 cents, more or less; g.s.b., glass-stoppered bottle, 18 cents, more or less. The cost of the bottles and vials as given is to be added to the price of the articles in all cases. In remitting cash for goods, remember to include price of package as per list below.

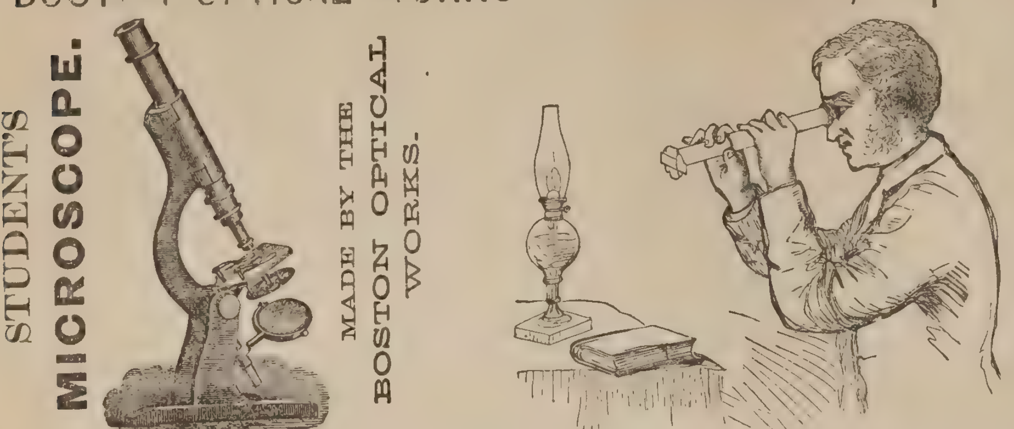
BOSTON OPTICAL WORKS — R. B. TOLLES, Supt.



Offer their Students' MICROSCOPES, 15-in. high, on Trunnions, with one eye-piece, one 1-in. objective, one ¼-in. objective, in Black Walnut Case, for $50 — on receipt of $51 it will be sent, safely packed, to any part of the United States.

Also, STUDENTS' MICROSCOPES for $62, $70, $90 and $102.

The Company are now making Dr. Cutter's **Clinical Microscope**, in two styles, with improvements, by which it is the most compact and convenient instrument to be found for the Physician and Traveller. Price, with one eye-piece and ¼-in. objective, $25 and $30. Gentlemen who have both the above instruments require but one set of the optical parts — making an important saving in the cost.

They also make, to order, **Tolles' first-class Objectives**, either "dry" or "immersion," and **Tolles' Improved Telescopes**. These instruments have a world-wide reputation as being second to no others.

All orders and correspondence must be addressed to

3t. **CHARLES STODDER, 75 Kilby St., Boston, Sole Agent for the Co.**

DR. GARRATT'S

CONSTANT

Electric Disk.

A neat self-acting *alloy electrique*, to be worn on the body or limb, as if a plaster. These simple *disks* are for general use. Any one can apply this *disk*, and the most delicate can wear it with comfort and relief. The electricity produced is primary and chemical; hence is felt only as a pleasant, lively warmth, brings out the sluggish humors, and is perfectly safe in all cases and conditions. They are clean, durable, and the least expense or trouble of all reliable electro-medical appliances for *localized electricity*.

These electric *disks* are a great improvement, for the best of medical electricity is provided without the expense of battery or operator. Constant in action while next the skin, the *disk* is worn days only, or nights only, and so becomes a successful *aid* for many a *lame* or weak back, stomach, side, or limb; for *cold rheumatism*, nervous cough, or dyspepsia, atony of any organ, pain or palsy. Retail price, $3.50.

The diligent electricity from this new magnesium-zinc *alloy* is now well attested and employed by leading physicians and surgeons. We are permitted to refer to the eminent Professor of Materia Medica and Therapeutics at Harvard College; to Professors Storer and Green; Dr. C. T. Jackson, State Assayer to Massachusetts; Drs. Codman & Shurtleff; Leach & Green; Metcalf, Restieaux, Brown, Joseph Burnett; and a large number of general practitioners, and other leading medical men.

P. S. — Dealers will find these Disks a superior article, compact, no way liable to break or injury, no losses, and pay well; a convenient, popular remedy. *For sale* by all first-class *Druggists*; in quantities (in *half-dozen, dozen*, and *gross* boxes), by Geo. L. Rogers, General Agent, 146 Washington Street, Boston, Mass. Orders filled with despatch.

FISH GUANO for sale by J. M. LINCOLN & SON, 140 Commercial Street, Boston.

EVERY PHYSICIAN

SHOULD HAVE

I. "The Medical and Surgical Reporter."

Published WEEKLY. Twenty large octavo pages of reading matter a week; Lectures, Original Communications, Hospital and Medical Society Reports, Periscope, Notes on Books, Editorials, Notes and Comments, Correspondence, News and Miscellany, Queries and Replies, etc. Two volumes a year, of over Five Hundred pages each. Good paper — good print — good reading. The most widely circulated, popular and generally read medical journal in America. Volume XX. began January, 1869.

Subscription price, Five Dollars per annum; and postage prepaid when paid *in advance*. *Send for a specimen*. For address, see below.

II. "The Half-Yearly Compendium of Medical Science."

Published in January and July. Over Three Hundred pages in each number. Good paper — good type. The most complete abstract of the medical journalism of the world published in the English language. None other does justice to American medical literature. It is in its second year, and is the most successful medical enterprise thus far ever started in this country.

Subscription price, Three Dollars per annum, including postage. *Send for a circular.*

III. "The Physician's Daily Pocket Record."

Admitted to be the best Physicians' Visiting List and Pocket Manual published. It contains many new features, among which are: A Patent Spring Clasp, a great improvement on the old-fashioned tuck; A List of New Remedies; Doses of Medicines by Inhalation, Hypodermic Injection, Suppositories, etc.; Classified List of Medicines, with doses and prices; Tables for Examination of Urine, etc.; Fee Bills, etc., etc.

☞ *It is* PERPETUAL, *being good a year from date of purchase.*

PRICE: — 35 patients a week, $1.50; 70 patients, $2.00; including postage, and name stamped on clasp when requested.

☞ All three of the above publications, when paid for *strictly in advance and directly to this office*, will be furnished, postage prepaid, for $8.00. *They cannot be furnished on these low terms through Agents or the Trade.*

☞ Liberal inducements offered to those who will interest themselves in extending the circulation of our publications.

BRADFORD ACADEMY

FOR YOUNG LADIES.

The Trustees of Bradford Academy would announce that the Winter Term of the sixty-seventh year of this institution will commence on the first day of December next, in the new building. This building was erected last year, and finished the present season. The rooms for the pupils are unrivalled. In the construction of this house every attention has been given to the health, comfort and happiness of those who are to occupy it. It will be newly furnished, and particular regard will be had to the health and development of the pupils.

Miss Johnson, who has been at the head of this Academy for twelve years, is assisted in every department by able teachers and the most eminent professors in history and the natural sciences. The course of study has been revised with great care, and it is believed is not excelled by that of any Female College in the country.

Board, including washing, fuel and lights, with tuition, will be $100 for the term.

Application may be made to Miss A. H. JOHNSON, Principal Bradford, Mass.

JOHN D. KINGSBURY, SECRETARY.

BRADFORD, MASS., Sept. 15, 1869.

Hypophosphites of Lime and Soda

COMBINED.

This combination, now so extensively known and understood, is fast becoming a favorite with physicians in the treatment of incipient phthisis. It combines with pure *Cod-Liver Oil* the nerve nutrient principle afforded by phosphorus in saline combination. It is pleasant to the taste, and does not disagree with patients.

Sold by Druggists throughout the United States.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. IV.—No. 5. BOSTON, NOVEMBER 1, 1869. FIFTY CENTS PER ANNUM. SINGLE NUMBERS, SIX CENTS.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.
RECEIPTS.—A receipted bill will be sent by return mail to any subscriber who will enclose with his subscription a three-cent postage stamp, for return postage.
A list of premiums is offered to those who obtain subscribers.

Familiar Science.

THERMO-ELECTRICITY AND ONE OF ITS APPLICATIONS.

It is well known that electricity may be developed or produced in various ways; as by friction, by chemical action, by magnetism, etc. One of the ways in which it may be generated is by *heat*. If one of two pieces of copper wire be heated, and an end of it be pressed against an end of the other piece, a current of electricity will pass from the hot to the cold piece, and may be detected by a delicate galvanometer. If pieces of any *two* metals be brought in contact, and the point of junction be heated or cooled, a flow of electricity takes place from one to the other. For example, when a bar of antimony, *A*, is soldered to a bar of bismuth, *B*, (see Figure 1) and their free ends are connected with a galvanometer, *G*, a current passes from the bismuth to the antimony when the junction is heated. When *S* is cooled by applying ice, or otherwise, a current in the opposite direction is produced. Such a combination of metals is called a *thermo-electric pair*, and the electricity produced is called *thermo-electricity*, that is to say, *heat electricity*.

Figure 1.

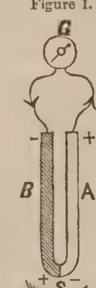

Figure 2.

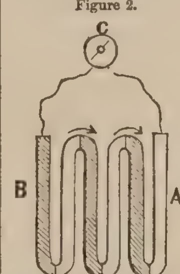

A single pair of this kind has very little power, but when several pairs are united, as shown in Figure 2, a stronger current is obtained. Such a collection of pairs is called a *thermo-electric battery* or *pile*, or, more concisely, a *thermopile*. The upper row of soldered ends forms one *face* of the pile, and the lower row the other face.

If, now, one of these faces be heated more than the other, an electric current passes through the bars; and the greater the difference in temperature between the two faces, the stronger is the current.

We have said that the current may be detected by a *galvanometer*, but perhaps some of our readers may not know what *that* is. It consists essentially of a magnetic needle, arranged so that the current of electricity can be made to pass around it through wires parallel to its position when at rest. When thus at rest, of course it points north and south, but as soon as the current passes through the wires it causes the needle to swing round towards an east and west position. The stronger the current, the farther it turns aside, so that its motion serves not only to detect the electricity, but also to measure it.

When the galvanometer is used with the thermopile, one end of the wire passing round the needle is connected with the free end of the antimony bar, *A*, in the figure above, and the other end with the free end of the bismuth bar, *B*.

Such an apparatus, if delicately constructed, is the most sensitive of all thermometers. If the hand be held several feet from one face of the pile, the heat radiated from it will set the electricity flowing through the soldered bars and deflect the needle of the galvanometer. If a piece of ice be held at considerable distance from the same face of the pile, the needle instantly swings in the opposite direction, showing a current whose course is opposite to that of the former one.

But of what use is this thermometer, except as a scientific plaything? It has been the means of settling a question which had long been matter of dispute among scientific men. Is there any heat in the rays of the stars? Does any warmth come to our world mingled with the light which finds its way across the immense interval which separates them from our solar system? The ordinary thermometer does not indicate the slightest rise of temperature when exposed to the rays of the stars. It is very far from being sensitive enough to measure the small amount of heat in the stellar beams. But the thermopile has caught the warmth radiated from a star, has measured it again and again, and has thus solved the problem which so long baffled the skill of the wise men.

The method of using the pile in this investigation will be understood from the following description:

"It is this instrument which Mr. Huggins has employed in his researches into the heat of the stars. It was attached to his telescope so that the image of a star formed by the eight-inch object-glass might fall upon the surface of the pile. So delicate was the arrangement, and so susceptible to the minutest variations of temperature, that his apparatus often had to be left for hours until it had come to equilibrium and the needle was at perfect rest. When the time arrived for experiment, the shutter of the observatory dome was opened, and the telescope was turned upon a part of the sky near a bright star, but not actually on the star. The needle was then carefully watched, to determine whether the change of position produced any effect. After waiting sufficiently long to be certain that there were no signs of change, the telescope was moved over the small distance necessary to bring the image of the star directly on the face of the pile, when the needle was immediately seen to move. The telescope was then moved slightly away from the star, when the needle returned to its place. The stellar ray was then again made to fall upon the pile, and again the needle was thrown out of its position. These observations were repeated, with great care and patience, on different stars, and at different times, until it has been conclusively established that heat is a constituent of the stellar rays."

The star Regulus, which was one of those selected by Mr. Huggins for his experiments, is so far away from our earth that its light, flying at the rate of 190,000 miles in a second, takes *twenty-six years* to reach our earth. The rays of heat which struck upon the face of the

thermopile, started the electric current through its network of metallic bars, and swerved the needle of the galvanometer, started from their starry home twenty-six years before. The old astrologers taught that the stars had an influence upon the events which take place on this earth of ours; and so indeed they have, in a more wonderful way than Chaldean sage ever conceived. Modern science has shown that all matter, however distributed through the immensities of space, is essentially the same, being made up of the same chemical elements with which we are familiar in this little corner of the universe. It has proved, too, that *force* is everywhere the same in its nature, and everywhere indestructible, though everywhere capable of infinite transformations. The *heat* which we can produce by our lamps and furnaces may be transmuted in the thermopile into that other form of molecular motion which we call *electricity*, and this again into ordinary *mechanical motion* in the needle of the galvanometer; and the heat which has come to us from the most distant star, though too slight in amount to be directly appreciable by our senses, is found to be capable of going through the very same metamorphoses and manifesting its energy in the same varied phenomena.

Verily, truth is stranger than fiction, and the sober realities of science more wonderful than any Arabian tale of magic.

COPPER IN THE COLORING OF A BIRD'S WING.

The *turaco* or *plantain-eater* of the Cape of Good Hope is noted for the beauty of its plumage, and especially for the rich red upon its wings. This red coloring-matter has been analyzed, and found to contain nearly six per cent of copper, which cannot be detected by the ordinary tests, nor removed from the red compound without destroying it. This coloring-matter is, in fact, a natural organic compound, of which copper is an essential constituent. The name *turacine* has been given to this substance. Traces of copper had previously been found in animals, as in oysters, which, living in streams flowing from the neighborhood of copper mines, had assimilated certain salts of that metal. The copper apparently had no effect upon the health of the oyster, though it did upon the health of people who ate the bivalve. But in this case, as in all others of the kind heretofore observed, the presence of the copper was clearly accidental; while in the turaco the metal is a normal part of the coloring-matter of the bird's plumage. Of course it must be obtained in minute quantities with the food, and stored up in this singular way in the system of the animal. In the very same feather, partly red and partly black, the copper is found in the red parts, but not at all, or the merest trace, in the black. If a few fibres from the red part be burned, the spectrum of copper is readily detected in the flame.

It is a curious fact that this red in the wing of the turaco is not a *fast* color. A pair of fine birds which were kept in captivity washed it all out of their plumage in a few days by bathing in the water which was left them to drink, the turacine being soluble in water. Except for the loss of their beauty, the birds did not appear to be any the worse for the change. It would seem, therefore, that we have here an instance of the elaboration of a chemical substance perfectly unique in its nature and containing a metal whose salts are usually regarded as poisonous to animals; and yet the sole purpose which, so far as we know, it serves in the animal economy, is one of pure decoration. How will those who take an exclusively utilitarian view of the plan of creation explain this?

THE WORLDS IN SPACE.

At the late meeting of the British Association for the advancement of science, held at Exeter, England, Professor Miller gave a Saturday evening lecture which was a very attractive popular presentation of some of the great facts in astronomical science, followed by an account of the most recent discoveries in that department of research. The difficulty about astronomical facts is that the mind must make an unwonted effort to grasp them. They transcend our familiar figures and standards so enormously that we listen to them without fully comprehending them. A general and vague notion of void immensity is left in the mind, but nothing more. Professor Miller, however, put the main facts of the science before his hearers, with great clearness; and those who listened to him could not but come away with new views of that majestic creation, of which our own world, vast as it appears to us, forms so minute a part. Abandoning the hard language of figures and the usual formulas, the lecturer invited his hearers to construct an orrery in their imaginations. It was Sir John Herschel's illustration of the solar system, with some modifications, extended to take in the immensely broader domain of the stellar universe.

We are to suppose ourselves on a vast level plain, in the centre of which we place a globe, two feet in diameter, to represent the sun. At the distance of seventy-two yards from this globe, we place a pea, which figures the earth, eight thousand miles in diameter; with the moon under the form of a mustard-seed, seven inches from the pea. Between the earth and the sun, at distances of about twenty-seven and forty-seven yards from it, Mercury and Venus would be placed, the former as a small shot, the latter as a pea, a little smaller than the earth. Mars would be another small shot, one hundred and nine yards from the centre; Jupiter and Saturn, oranges of small size, the former a quarter of a mile, and the latter two-fifths of a mile, from the sun; while Uranus and Neptune would be plums, at distances of three-quarters of a mile and a mile and a quarter respectively. Put in the asteroids and satellites in their proper places on the same scale, and the circular field of two miles and a half diameter would then be an exact map of our solar system, the little celestial family to which the planet on which we live belongs. With regard to the nearest of the kindred systems—the next-door neighbors of our planetary household—even a scale so liberal fails us instantly. The earth's surface, rolled out flat, would not be wide enough to admit into the chart the brightest of the fixed stars. To put down Sirius in his right place, he should be 40,000 miles away from the two-feet globe which represents the sun. And let it be borne in mind that this distance is merely "to scale," *the earth being a pea.* The true interval between that bright star and the earth is so prodigious, that light, which travels seven times round our globe in a second, and reaches us from the sun in eight minutes, takes *twenty-three years* in the journey from Sirius to our eyes.

These facts have long been known; but another fact of more recent discovery invests them with an entirely new interest. Immensely distant as these bodies are, science has compelled them to disclose the secrets of their composition. Some of the telescopic stars are hundreds of times farther off than Sirius; yet, with the aid of the spectroscope, astronomers have catalogued the component substances of those distant suns, and have revealed the momentous fact that the bodies which spangle immeasurable space contain matter identical with that which we know here in our own little world. Even the light of the nebulæ, which are so far away that figures cannot express the bewildering interval, yields its testimony that throughout the whole visible universe the material of creation is the same. A succession of ingenious investigations into the nature of the red flames which shoot from the sun, has shown that vast eruptive conflagrations of hydrogen are blazing there, while many of the metals familiar to us are vaporized in the inconceivable heat of that heaving sea of fire. Doubtless these metals, gases, and other forms of common matter are differently mingled, and under different conditions, in the various planets, and suns, and systems; but the new optical chemistry has demonstrated that the worlds, as far as we can reach them with eye and glass, are all formed of the same primary materials, "aggregated," Professor Miller said, "into masses which, though differing from one another in composition, like the various veins of ore that occur in mines upon the surface of our globe, are yet all evidently of common origin; all obey the same laws, and all possess a chemical nature similar in kind." These intimate relations between bodies so far distant must inspire us with a new sense of the unity of creation; and (again to quote the learned lecturer) "if the measurement of such distances, the estimate of the mass and the magnitude, the calculation of the velocity of these bodies in space, and the determination of their chemical composition at distances the accurate conception of which transcends even the ability of imagination—if these, I say, be not beyond the power of man, it may well be supposed that there is no limit to the discoveries which are within his reach."

This exultation at the rewards of man's patient inquiry into the secrets of nature is a just and proper pride. This joyous hope of discoveries to come, which will surpass even such prodigious results, is no wild dream, but a well-grounded and sober anticipation of the glorious extension of the realm of knowledge. From the height already reached, after long and weary labor, a new landscape of boundless extent is seen outspread before us, and we *know* that its complete exploration can make no demand upon our powers beyond what they have already been able to bear. It is only a question of time and patience, not of strength and skill.

The discovery that all the visible worlds are of like nature to ours, suggests the thought that, as matter is common to this "world of worlds," so *life*, veiled in material forms, is also common. Hydrogen—now known as a metal, even on our own earth, in alloy with palladium—is burning with jets of fierce flame ten thousand miles high upon the sun's photosphere, and perhaps is frozen into blocks of manageable building material in the planet Neptune. In different worlds matter is differently conformed and employed; but, since it is universal, how strong is the presumption that life also, under unimagined conditions and guises, accompanies all its countless transformations! And when we have ascended so far above this poor little speck, the earth, as to conceive the planets peopled; when we have launched on beyond them into the abyss of space, to follow our astronomers to Sirius and the fixed stars, and to imagine the planets which revolve about those distant suns as also the abodes of wonderful and lovely forms of sentient life, is it possible that we should fail to recognize the unity of design and of power embodied in the government of the universe? Astronomy, reënforced by the marvellous aid of chemistry, cannot but develop a wider and bolder idea of the love, the wisdom, and the purposes of Providence. Well might the cathedral preacher at Exeter, on the day after Prof. Miller's lecture, discourse

from the text, "What is man that Thou art mindful of him?" — not in the spirit in which the inquiry is usually discussed, but dwelling rather upon the answer found in the same Psalm, "Thou madest him to have dominion over the works of Thy hands"; and enlarging, with devout thankfulness, upon the exalted heritage of man as little lower than the angels, endowed with the capacity of tracing the thoughts of God in the laws of the natural world, and finding, at every step, fresh proof of that Divine love, of which the written Word, with its messages of grace, is but another revelation.

DEEP SEA SOUNDINGS.

A systematic course of deep-sea dredging was carried on last year by Dr. Carpenter, Prof. Thomson, and other naturalists, under the auspices of the Royal Society, and with the aid of the British government, the vessel having been furnished by the Admiralty. Dredging was successfully done at a depth of 650 fathoms; and a varied and abundant submarine fauna was found at depths where it had been supposed that no animals, or only those of the lowest type, could exist.

This summer, another expedition of the same kind, with a larger vessel, has been organized, and dredging has been carried down to more than 2,400 fathoms — a depth nearly equal to the height of Mt. Blanc. Animal life has been found, even at that depth, in considerable *variety*, though its *amount* and *kind* are limited by the Arctic coldness of the temperature. Careful soundings with thermometers made for the purpose proved that the temperature decreases as the depth increases. The fall of the mercury is at first more rapid, but soon becomes pretty uniform. All the observations confirm the theory that there is a regular flow of warmer water from the equator towards the poles, and of colder water from the poles towards the equator, the former current extending down some 700 or 800 fathoms, and the latter occupying the lowest depths. These deep waters have been analyzed, and are found to contain a large proportion of carbonic acid gas, and also of organic matter.

THE ICEBERG.

"Observe the little bit of ice that clicks in your tumbler at dinner-time. Observe it closely, and you will perceive how very small a part of it floats above the surface of the water — not more than one-eighth, at the farthest — while the remaining seven-eighths float beneath. Now, this little bit of ice is an iceberg in miniature — an iceberg in every essential feature, except that it did not, in all human probability, come from Greenland. In shape, in general transparency, in the play of light upon it, in its prismatic character, in its frequently-cavernous form, in the general shape of the projecting tongues which lie beneath the surface of the water, in the delicate mist which plays around its summit in the warm air, it is the very image of those great, floating monoliths of the Arctic frost which come sailing down Baffin's Bay with the polar current, in all their stately grandeur and magnificence, scorning, as they tread their watery way, the great billows of the ocean with a cold disdain, sending them away, moaning and shattered, in defeat, chilling the air for leagues around, yet gathering to themselves the gorgeous colors of the sky; immovable from their steadfast course, and majestic as the 'silvery moon,' that, like the iceberg, 'bathes its sides in the trembling wave.'

"The iceberg is the largest independent floating body in the universe, except the heavenly orbs. There is nothing approaching it, within the range of our knowledge, on this globe of ours; and yet it is, as we have seen, but a fragment of the ice-stream, which is, in its turn, but an arm of the ice-sea. And yet the iceberg is to the great quantity of Greenland ice as the paring of a finger-nail to the human body; as a small chip to the largest tree; as a shovelful of earth to Manhattan Island. Yet magnify the bit of ice in your tumbler until it becomes, to your imagination, a half a mile in diameter each way, and you have a mass that is far from unusual. Add to this a mile, two miles in length, and you have what may be sometimes seen. I have sailed alongside of an iceberg, two miles and a half, measured with a log-line, before coming to the end of it.

"The name signifies, as we have seen before, ice-mountain; and it is truly mountainous in size. Lift it out of the water, and it becomes a mountain one thousand, two thousand, three thousand feet high. In dimensions, it is as if New York City were turned adrift in the Atlantic, or the Central Park were cut out and launched in the same place. An iceberg of the dimensions of the Central Park is far from unusual. And its surface is not in form unlike it either. It is undulating like the Park, and craggy, and crossed by ravines, and dotted with lakes — the water of the lakes being formed from the melting snows of the late winter, and also of the ice itself after the snows have disappeared before the influence of the summer's sun. I have even bathed in such a lake, although I am glad to say but once, and that was in 'those days of other years,' when the youthful insanity is strong to *say*, 'I have done it' — a disease which I believe to be amenable only to that treatment popularly known as 'sad experience.' Skating on an iceberg lake is far more satisfactory and sensible.

. . . . . .

"We still stood upon the summit of the bluff, overlooking the fiord and the ice-stream.

"The ice-stream had been constantly emitting sounds, sometimes by the breaking off of a small fragment from its front, sometimes by a partial crack opening far up in the body of it, as it strained in its rocky bed; but now a loud report, as of 'deep-mouthed thunder,' broke from its profoundest depths — seemingly, indeed, as if from the very bowels of the earth. It fairly shook the ground on which we stood.

"Philip said, quietly, 'The ice-stream is going to calve.'

"An instant afterward the report was repeated, louder and still more startling. The shock beneath my feet was more sensibly felt: it seemed like the first warning cry of a coming earthquake.

"Philip said again, 'See! it is rising.'

"A portion of the glacier was being lifted by the sea. A great wave was rolling back with this movement of the ice, and was dashed wildly against the ice in front.

"An instant more, the sound, which was before so deep and loud, now broke through the air with a crash that was almost deafening — as when a heavy gun is fired near by.

"I knew that a monstrous crack was opening in the ice-stream.

"The position of the crack was soon seen. A fragment, of enormous proportions, had been disengaged. Its front raised itself aloft as if it were some great leviathan endowed with life, and while it rose the crack opened wide. The unwieldy mass plunged forward, crashing against other ice-masses, scattering the broken fragments to right and left with irresistible force. Then the inner side rose up and the front sank down, while vast volumes of water that had been lifted with it went roaring and hissing over its sides into the foaming and violently agitated sea.

"Thus an iceberg had been born.

"It would be impossible, with mere words alone, to give any adequate idea of the action of this new-born child of the Arctic frosts. Think of a solid mass of ice, a third of a mile deep, and more than half a mile in diameter, hurled like a mere toy into the water, and set to rolling to and fro by the impetus of the act — as if it were Nature's merest football — down one side, until the huge mass was nearly capsized; then back again, and down the other side, with the same unresisting force; and so on, up and down, swashing to and fro, for hours, before it comes finally to rest. The disturbance of the water was inconceivably fine; waves of enormous magnitude were rolled up with great violence against the glacier, covering it with spray; and vast billows came tearing down the fiord, their progress marked by the crackling and crumbling of the ice, which was in a state of wildest agitation throughout a space of several miles. Over the smaller of the icebergs these billows broached completely, breaking as if a tempest were piling up the waters, and heaving them with infuriated might against a rocky shore. Then, to add to the commotion thus made, the great, wallowing iceberg that was the cause of it all was dropping fragments from its sides with each vacillation, the reports reaching the ear above the general din and clamor. Then other bergs, as they were successively set in motion by the waves, also dropped pieces from their sides; and at last, as if it were the grand *finale* of the piece — the clash of the cymbals and the big bass-drum of Nature's grand orchestra — a monstrous berg, near the middle of the fiord, split in two, and, during the noise of moving waters and crumbling ice, filled the air with a peal that rang among the bergs and crags, and, echoing from hill to hill, died away only in the void beyond the mountain-tops; while to the noisy rhythm the huge leviathans of the fiord dance their wild, ungainly dance upon the waters.

"It was many hours before this state of wild unrest was succeeded by a calm; and when at length the iceberg that I had seen born came quietly to rest, and the other icebergs had ceased to dance their dance upon the troubled sea, and the billows had stilled their lashings, it seemed to me that, in beholding this birth of an iceberg, I had beheld one of the most sublime exhibitions of the great forces of Nature. It was indeed a convulsion!" — *Dr. I. I. Hayes, in Appleton's Journal.*

Experiments made at the Botanic Garden, London, showed that a leaf of the *Victoria Regia* would sustain a weight of 426 pounds before sinking. The leaf selected for the trial is said to have been one of the smaller ones of the plant.

Arts.

POTASH FROM A NEW SOURCE.—THE STASSFURT MINES.

The alkaline salt potash is so important in agriculture and the arts, that we think a full explanation of the method of obtaining it in large quantities from a new source will be interesting to the readers of the *Journal.* Potash, as is well known, was formerly the cheapest of the alkalies, but it is now the dearest; and in every possible case its place has been filled by one of the other alkalies, usually soda. The principal, and for a long time the only, source of potash, has been the ashes of plants; but within a short time potash salts have been discovered in vast amounts at the salt mines of Stassfurt, Prussia. Their value was not at first recognized, but did not long escape the notice of the very eminent chemist, Heinrich Rose, who pointed out their importance. At the present time, they are extensively worked. They are found overlying the salt-beds, in layers of various thicknesses, and are associated with salts of lime and magnesia. The principal forms in which they occur, are known as mineral species under the names of polyhalite, sylvite, carnallite and kainite; accompanying them are found rock-salt, anhydrite, kieserite, tachydrite, and boracite. Polyhalite is a hydrated sulphate of potash, lime, and magnesia; sylvite is chloride of potassium; carnallite, a double chloride of magnesium and potassium; and kainite, a compound of hydrated chloride of potassium and sulphate of magnesia. Of the associated minerals, it need hardly be said that anhydrite is the anhydrous form of sulphate of lime; kieserite is a hydrated sulphate of magnesia; tachydrite, a double chloride of calcium and magnesium; and boracite, a borate of magnesia.

Carnallite is the material worked for the extraction of potash. It is found mixed with rock-salt, kieserite, and small quantities of the other species mentioned above. As the mineral comes from the mine, it contains about one-sixth its weight of the potassium salt (the chloride), the rest being rock-salt and the chloride of magnesium, which is combined with the potassium salt as carnallite. In the process used to get the chloride of potassium in a reasonable degree of purity, advantage is taken of the different degrees of solubility of the various substances with which it is associated. The chlorides of potassium and magnesium are much more soluble than the chloride of sodium; so by treating the salt mass with an insufficient quantity of hot water, the two first-named salts are dissolved, while the most of the common salt is left behind undissolved. Chloride of magnesium is very soluble in cold water, and common salt is equally soluble in hot and cold water, so that both these remain in solution, while the potassium salt crystallizes out in a state of tolerable purity, about 80 or 90 per cent. of chloride.

This product is good enough for commercial purposes and is used for making other salts. By further concentration of the mother liquor, the original salt, carnallite, deposits, and can be again worked over, while chloride of magnesium only is left in the solution. From the chloride of potassium the sulphate can be prepared by treatment with sulphuric acid; and from the sulphate the carbonated and caustic alkali, by Leblanc's process. This method, however, requires the use of a material (the acid), which is obtainable at the mines only at a considerable expense. It was therefore desirable to employ, if possible, the natural sulphate of magnesia, which is very plentiful at Stassfurt. After a great

deal of experimenting, this was finally accomplished in a very ingenious manner by the formation of a double sulphate of potash and magnesia. This is done by simply adding sulphate of magnesia to the solution of chloride of potassium, a double decomposition taking place, with the production of sulphate of potash and chloride of magnesium. But the sulphate of magnesia, as mined, is mixed with common salt, from which it must first be freed.

The mixture of rock-salt and sulphate of magnesia is placed in water. The magnesia sulphate is but slightly soluble in the brine which is soon formed and collects at the bottom of the vessel, from which it is removed and used to form the double salt above mentioned. By careful treatment of the double salt, a part of the sulphate of magnesia can be got rid of, and from the residue carbonate of potash produced by Leblanc's process. Another mode of treating this double salt, is by a solution of chloride of potassium, and then, by a series of crystallizations, are obtained pure sulphate of potash, the double sulphate again, and a double chloride of potassium and magnesium (carnallite). The sulphate of potash is of course fit for the market, but the other salts are again worked over in the ways previously described.

As already stated, the deposits at Stassfurt are of enormous extent, and from them potash and its salts are now produced in such great quantities that their cost has been very materially lessened, so that even in agriculture they can be advantageously used. The processes employed for their extraction seem simple, and indeed are not very complex, yet are of a very interesting character, must be carried on with care and judgment, and require skill in manipulation. Separations of the kind we have been describing, are only possible on a large scale. One of the most important points connected with them is the manner in which the various mother liquors are brought into use. For instance, if the raw mass of rock-salt, chloride of potassium, and magnesia salts, instead of being treated with pure water, is acted upon by a mother liquor, already saturated with the two former, it is evident that almost all of the magnesia compounds will be dissolved, leaving the alkaline chlorides behind. Again, in the process given above, by which pure sulphate of potash is obtained, it will be noticed that at the same time other salts are formed, only to be worked over again. The final mother liquors contain very little besides magnesia salts, and are utilized to some extent as a source of magnesia.

TOLLES' NEW METHOD OF ILLUMINATING OPAQUE OBJECTS FOR THE MICROSCOPE.

Microscopic objects may be classed in two groups; those that are transparent, and those that are opaque. The first can be examined by the highest amplifying power that the optician can produce, but until recently it has been impracticable to apply high powers to opaque objects, for the reason that the lens must approach so near to the object (often within one one-hundredth of an inch, and in case of very high powers, of French or English make, one-half of that distance), that the lens itself would prevent any light from reaching the object. In 1865 or 1866, Prof. H. L. Smith, then of Kenyon College, Ohio, devised a plan by which light was admitted through the side of the tube of the microscope, and reflected down through the lenses of the objective to the object, which was thus illuminated and seen by the observer. Prof. Smith described his invention in the *American Journal of Science.* When his description reached England some of the London opticians attempted to accomplish the same result, by using modifications of what they called the "American Contrivance," after plans that Prof. S. had tried and abandoned as unsatisfactory.

None of these plans have come into general use; the great difficulty with them has been that most of the light is reflected to the eye of the observer by the lenses, before reaching the object, thus producing a glare, which renders the object indistinct. By very careful and tedious manipulation, the writer has sometimes obtained a pretty good effect with Prof. Smith's illuminator, but more often, after working a long time, has failed.

Soon after Prof. Smith's instrument was described, Mr. Tolles, then in Canastota, produced an instrument varying materially from the others. In this a prism is inserted in the side of the objective, between the front and middle combinations, of such a shape that a beam of light, received at the side of the objective, is thrown by a totally reflecting surface through one side of the front lens, at such an angle that none of it is reflected, but all passes through and is condensed on the object, and from that reflected back to the eye. Only one of these instruments (now owned by a physician of this city), was then made. Recently Mr. Tolles has made two more of them, and their performance is such as to promise that little, if any, improvement can be expected in this direction. Opaque objects are seen with 4-10ths and 1-4th inch objectives, (from 200 to 500 diameters) brilliantly illuminated on a black background. The appearance of diatoms is similar to that obtained with the parabola, but the details of surface are shown with a distinctness never before seen. Of how much utility this is to prove, and what discoveries are to be made in the works of nature with it, are among the problems that the microscopists are called on to solve. C. S.

GREAT LABORATORIES.

The new chemical laboratory of Berlin University has recently been opened. It contains 21,680 square feet, and has cost nearly $250,000, which has been paid by the Russian government. The celebrated Dr. A. W. P. Hofmann has charge of it.

The magnificent edifice for physiological, chemical, and physical experimentation just finished at Leipzig, is said to have cost $300,000. It surpasses anything of the kind in Europe.

Through the influence of Claude Bernard (who has just been made a Senator and a member of the French Academy), the project of a similar structure in Paris has received a favorable hearing from the Emperor, and will doubtless be carried out at once.

Protection of Wood from Fire. — The *Deutsche Industrie Zeitung* says, that at one of the collieries in Westphalia, woodwork not exposed to the open air is painted with a mixture of 5 parts of alum, 7 parts of rye meal paste, and 3 parts of finely divided clay. For woodwork exposed to the weather a mixture is used, consisting of $2\frac{1}{2}$ parts of sal ammoniac, 1 part of sulphate of zinc, 2 parts of joiners' glue, 20 parts of zinc-white, and 30 parts of water. These mixtures prevent wood from bursting into a flame when ignited, and greatly delay its destruction even when a severe fire is raging.

We see that John H. Weeden, of Waterbury, Conn., has taken out a patent for a "head-rest attachment for church-pews," which is intended "to support the head of the worshipper (or *sleeper?*) when inclined," and which "may be conveniently detached from the pew when not required for use."

A Few Recent Inventions. — A Michigander has invented a whistle for sailing-vessels, to be used for the same purposes as the steam-whistle. It is worked by compressed air, forced into a reservoir by a bellows.

At a late meeting of the Royal Society of London, there was exhibited a pneumatic signal apparatus, which is so arranged as to display a green, red, or white light at the mast-head, according as the helm of the ship is turned to starboard, port, or midships. If generally adopted, it would render collisions at sea well nigh impossible.

There was also shown a self-registering ship's compass, which records all the movements of the vessel on a ribbon of paper kept moving by clock work.

Another curious contrivance was an automatic trigger for firing torpedoes under water. When a ship comes over the place where the torpedo is sunk, the masses of iron in the vessel attract a magnet, which pulls the trigger and ignites the charge.

Much interest was excited by an instrument with the pretty name of *Stethosphygmograph*, which gives simultaneous indications of the movements of the heart, pulse, and lungs.

Simple Preservation of Copal Varnish. — Dissolve one part of camphor in twelve parts of ether. When the camphor is completely dissolved, add four parts of colorless and finely powdered copal. The copal to be carefully selected. Place this mixture in a bottle and shake until the copal is swollen and partly dissolved, then add four parts of proof alcohol and one quarter of a part of rectified spirits of turpentine — shake again sufficiently and the varnish is ready for use. After the bottle has stood several days, however, the varnish divides into two distinct strata; the lower reiher in copal, but the upper finer and perfectly colorless. Prof. Boettger, the author of the formula, claims the superiority in transparency, elasticity, hardness, and durability for this varnish. The lower stratum may be again treated with camphor, etc.

Madder. — The place which madder occupies among dye-stuffs with the calico-printer has been compared to that which iron holds among metals with the machinist. It owes its value as a dye to two organic compounds, *alizarine* and *purpurine*. The former has recently been obtained artificially by German chemists, but it is not yet known whether it can be manufactured cheaply enough to be of commercial importance. Should it come to be used instead of the natural root, hundreds of acres now employed in the raising of madder will be set free for other agricultural purposes. In this way, a single chemical discovery may give a new direction to the industry of thousands, and even of whole nations.

Hallogenin. — Under this name, a mixture is sold in Germany to prevent the forming of incrustations in steam boilers. It is said to answer the purpose very well. It consists of 65 per cent of sal ammoniac, 17 per cent of chloride of barium, and 18 per cent of catechu.

A Chemical Experiment. — When Isaac Hopper, a member of the Society of Friends, met a boy with a dirty face or hands, he would stop him, and inquire if he ever studied chemistry. The boy, with a wondering stare, would answer "No." "Well, then, I will teach thee how to perform a curious chemical experiment," said Friend Hopper. "Go home, take a piece of soap, put it in water, and rub it briskly on thy hands and face. Thou hast no idea what a beautiful froth it will make, and how much whiter thy skin will be. That's a chemical experiment; I advise thee to try it."

AMMONIA AND COALS.

In London over 1,000,000 tons of coal are used annually in making gas. In this coal is contained a small quantity of nitrogen (not over one per cent), from which is derived the ammonia so largely employed in agriculture and the arts. The utilization of this, formerly a waste product, has added millions of dollars to the wealth of England. In London alone, 10,000 tons of sal ammoniac are produced by the gas manufacturers annually, and in the United Kingdom more than 100,000 tons. How insignificant appears this trace of nitrogen in coals, about one pound in the hundred, and yet we see how important it becomes when manipulated by the chemist and compelled to enter into compounds of the highest usefulness in the industrial arts. It is impossible to examine attentively into any of the art processes, without being impressed with the important service which chemistry has performed in facilitating and perfecting the same, and in utilizing waste products.

The most ancient building in Paris, and the only one dating back to Roman times, is the *Palais des Thermes*, the ruins of Baths erected about A. D. 360. They are in the gardens of the Hotel de Cluny, and are carefully preserved.

The next oldest building is the most ancient *hospital* in Europe, and perhaps in the world, — the *Hotel-Dieu*, near the Cathedral of Notre Dame. It was founded about A. D. 660. The ancient pile is soon to be demolished to make way for a new structure of palatial extent and splendor.

Parisian Copying Ink. — Take 30 parts by weight of extract of logwood, and 7½ of crystallized carbonate of soda; boil these with 240 parts of water, and add, while vigorously stirring, 30 parts of glycerine. When the fluid has become cold, dissolve in it 1 part of neutral chromate of potassa, and add lastly 7½ parts of gum arabic, previously made into a thick mucilage with water. It is not necessary to moisten the paper in using this ink.

M. Morren has found that several inorganic substances are decomposed when a ray of sunlight is made to pass through them. Sulphurous acid gas, for example, is broken up into oxygen and vapor of sulphur. He has also found that a solution of sulphate of quinine, even in very thin layers, arrests the chemical rays as completely as a thick plate of yellow glass.

Electric light, produced by magnetic-electrical machines, is to be used for the signal lamps of the Steamers of the Transatlantic French Steam Navigation Company.

Agriculture.

ABOUT GRAPES.

The present season has been quite a favorable one for grapes in Eastern Massachusetts, and we trust it has been generally favorable throughout the grape-growing region of the country. We have fruited this year about *thirty varieties*, embracing all those which have had any special claims to attention among grape growers, in this cold latitude. The growth, quality, and time of maturity and ripening of each have been carefully noted, not only this year, but for several years, and we are now ready to declare our preferences and also give reasons for entertaining those we have. Out of the thirty varieties, there are but *ten* which are worthy of special attention from growers in this locality. They are the Concord, Delaware, Hartford, Prolific, Adirondack, Diana, Rebecca, Allen's Hybrid, Iona, Israella. All but one of these have been perfectly ripened in our vineyard at Lakeside the present autumn, and that is the Iona. This grape will not do for Massachusetts. It is too tender and too late, and besides, it does not ripen evenly. Upon each bunch a few berries have ripened quite well, while the remainder were entirely unfit for eating. It is evidently an excellent grape, beautiful in form, color, and in the grouping of the berries upon the stem. It appears to be a good bearer, and the vine is nearly as hardy as the Rebecca. The fruit when ripe resembles the best foreign varieties. We think this grape, when grown in the Middle and Southern States, will prove to be a great favorite. The best, the most delicious grape that can be grown in the open air in this section, is the Delaware. We do not believe that by any process of hybridising, or by growth from seed, a better grape will ever be produced suited to northern climates. Indeed, do we need or want a better grape? If we can grow this splendid fruit in all its perfection here, let us accept the boon with thankfulness, and not complain that we are unable to do better. The Delaware is a first-class grape; it is sufficiently hardy, it is a generous and constant bearer, it is not liable to mildew, it ripens well eight years out of ten, it is a small grape, and the berries cling firmly to the stem. These are certainly strong recommendations, and before we consign such fruit to neglect or forgetfulness, let us be sure we have a better one.

The Concord must long remain a standard fruit for vineyard culture. It is not as good as the Delaware, but it is perfectly hardy, a good bearer, thrives on weak silicious soils, and does not fall from the stem. We are thankful for the Concord. Bushel after bushel of the fruit has disappeared in our family during the present autumn, while surrounded by an abundance of other and more highly vaunted varieties.

The Adirondacks and Israellas are good and early grapes. They are worthy the attention of cultivators, if the vines are sold at prices no higher than Delawares or Concords. It is high time the deceptions practised by vine-raisers and nurserymen ceased. The *new* varieties recommended and sold at enormously high prices, have not, in most cases, proved as good as the old varieties. We advise our readers to cling to our long-tried good grapes, and pay no attention to the statements of interested parties regarding new kinds, which they offer at high prices. Fortunes are made by speculators in vines, plants, seeds, etc., while there is no improvement found in the growth or quality of the plants or grains.

THE CATTLE SHOW AND FAIR AT GREENFIELD, MASS.

The annual fair of the Franklin County Agricultural Society was held at Greenfield, the last days in September, and after a thorough examination of the stock, fruits and vegetables exhibited, we have no hesitation in saying that it was the most extensive and the *best* which has ever come under our notice. In every particular it surpassed the N. E. Fair at Portland, and also the State, County, and other fairs which have been held this autumn, in N. England. The number of cattle on exhibition, was over 700, and there were *fourteen* herds, which included three hundred and fifty-one heads. The show was mostly made up of thoroughbreds, and all were of extraordinary size, beauty, and general excellence. There were three pairs of yearling steers, whose average weight exceeded 2,500 lbs. each pair. The town of Shelburne exhibited in one team 55 yoke of oxen, no one of which weighed less than 3,700 lbs. One weighed 4,800 lbs. Wm. H. Bardwell, of Greenfield, had four yokes, which weighed in the agregate 17,225 lbs. The heaviest yoke of cattle on exhibition weighed within a fraction of 5,000 lbs. Of the herds exhibited, the finest was owned by D. O. Fisk, of Shelburne, who had 35 noble animals. Geo. E. Taylor had 13 thoroughbred Short Horns, including a heifer that weighed 1,590 lbs.; another that weighed 1,400; and still another 1,290 lbs.

The most beautiful and valuable herd upon the grounds, was that owned by T. M. Stoughton, of Gill, numbering 41 pure blood Jerseys. The first view of this herd, as we came upon the hill overlooking the fair grounds, was exceedingly pleasant. They were feeding in one corner upon a rising ground quite at their leisure, and as a chime of fourteen bells had been distributed among them, the interest and novelty of the show was heightened by the pleasant accompaniment of music. The color and size of the animals varied and gave to the whole a very picturesque effect. Mr. Stoughton's Jersey cows produce upon an average about 15 lbs. of butter per week, which, owing to its great excellence, sells readily at 75 cents per lb.

We have not space in which to present even an outline of the interesting and extraordinary features of this exhibition. The fruits were as remarkable as the animals. It required over 700 plates to contain the specimens of apples, peaches, pears and the different varieties of grapes, which were entered for premium. The hills and rich meadows of Greenfield, Deerfield, Shelburne, Gill, etc., have furnished remarkable products the past season, and the farmers have reason to be proud of their magnificent herds, orchards, and grain fields.

The two days in which the fair was held, were delightful, and the crowds of visitors who thronged in the streets of the pleasant town of Greenfield, afforded evidence of the interest which centred in the show. Of the address, the Greenfield *Gazette and Courier* remarks as follows:

"Dr. Jas. R. Nichols, of Boston, the orator of the day, gave a most learned and interesting address, full of practical information to farmers, and presenting facts which all should learn and cherish. We shall publish the address in full in another week, our crowded columns not permitting it in this issue. A vote of thanks was tendered the Doctor by the Society."

The topic of the address was "*Some of the Relations of Water to Agriculture.*" We believe that at farmers' meetings no subjects of discussion should be introduced outside of those strictly relating to the interests of agriculture. If our noisy politicians and reformers cannot find some more appropriate place than cattle shows, for the utterance of their demagogical speeches, relating to labor reform, politics, women's rights, etc., they had better remain quiet.

THE COMPARATIVE VALUE OF CHEMICAL AND BARN-YARD MANURES.

A recent French writer states that 1,200 kilos, (about 24 cwt.) of chemical manure, costing 360 francs (about 72 dollars), produced on an average 54,222 kilos. of beet; while 72,000 kilos. (about 71 tons) of ordinary farm dung, also costing 360 francs, produced only 48,888 kilos. He gives the average of 160 cases of beet culture, all of the year 1868, as being about 4 tons to the acre in favor of chemical over farmyard manure. A contributor to the *Mark Lane Express*, of London, gives, in confirmation of these French views, the results of experiments made for fourteen years continuously in the raising of wheat and of barley, with the use of farm dung and various chemical

manures, and the advantage in every instance is clearly on the side of the artificial fertilizers. In some cases, the use of barnyard manure shows a loss instead of a profit.

It would be more satisfactory if the writer had explained precisely what the manures are, which in his tables of statistics he indicates only by numbers. In his preliminary remarks, he assumes the cost of barnyard manure as from 8 to 10 shillings a ton, and that of "muriate of ammonia, 16s. per cwt., sulphate of ammonia, 14½s., sulphate of potash, 15s., sulphate of soda, 4s., sulphate of magnesia, 6s., and superphosphate, 5½s. per cwt." These figures will enable the American farmer to compare the *relative* cost of the two kinds of manure in this country with their relative cost in Europe, and thus to judge (at least in a general way,) how the profit from the use of the two here will compare with the results obtained there.

RIPENING GRAPES BY CUTTING AWAY THE LEAVES.

The August number of *Cosmos* contains a paper on this subject by M. J. Comte, which was read at a meeting of the Agricultural Society of Agen. It appears to have been an old custom, and one still kept up in the South of France, to pull off the leaves of the vine so as to let the full sunlight fall on the grapes, which soon get an amber color and appear as if over-ripe. The author strongly condemns the practice. He states that the leaves, as arranged by nature, are absolutely necessary for perfecting the maturity of the grapes; in other words, for converting into grape-sugar a portion of the acids which are present in large quantity in the unripe fruit. This change is brought about by the addition of carbon to the acids, and this *carbonisation* (as Comte calls it) is effected by the leaves. Fully ripe grapes (of course, he is speaking of grapes which have a green color when ripe) should be of a pure green, and not of the yellowish shade exhibited by those which have been exposed to the light by stripping off the leaves. The taste of these yellow grapes is intensely sour, while that of the green-colored ripe grapes is sweet.

It is very short-sighted practice to keep hogs lean during the latter part of summer, and then endeavor to fatten them in cold weather, when it will require a much larger amount of food to produce the same result than would be necessary in warmer weather. Hogs should always be kept in condition, and then they can at any time be readily and cheaply fattened.

Feed for hogs should be ground, and steamed or boiled. In winter, boiling is much better than steaming, for the reason that it takes less fuel to boil a small quantity than to steam it; and further, that you can boil merely what is wanted for a feed at one time, and give it moderately warm. Small quantities of salt should be added to the feed for hogs, as they like it better, and it is more healthy.

Grapes.—Several vines in a cold grapery connected with our premises, present some singular features, which are new to us. Upon the vines, which are of the Black Hamburg variety, there is a large product of perfectly well matured, ripe fruit, and also grapes in large clusters, which are in the various stages of growth, and also blossoms just developing. The vines have been in blossom during nearly each month of the summer, and immature fruit has resulted therefrom. In fact, three or four crops have been progressing upon the vines at the same time. If any of our readers have vines behaving like these, we should like to be informed of it.

Boston Journal of Chemistry.

BOSTON, NOVEMBER 1, 1869.

DRY SEWAGE.

At the recent meeting of the British Association for the Advancement of Science, the subject of sewage was very fully discussed. The relative merits of water and dry sewage were the theme of a paper by Mr. E. C. Stanford, which embodied the results of considerable practical experiment. He contended earnestly for the dry system, and disposed of the objections raised as to the earth system, namely: the large quantity of earth required (three and a half times the weight of the excreta), and the difficulty of obtaining the requisite quantity, and drying it. He urged that both these difficulties were removed by the use of charcoal, and seaweed charcoal in preference, as the most porous, the most absorbent, and the cheapest. This charcoal, after being used, can be stored for any length of time, can be used several times, and requires only one-fourth of the weight compared with earth. It soon dries; and when convenient, it can be re-burned, by which means the whole of the ammonia is collected. The weight of the charcoal is increased about five per cent with each using; and if dried and re-used five times, is increased about twenty-per cent with each re-burning.

THE PHILOSOPHERS MADE FUN OF.

A very lively burlesque upon the late meeting of the British Association, at Exeter, has been published in London, with the title of "*Exeter Change*." Among the articles which it contains is one headed, "On the Alcoholic Compound termed Punch, by John T—nd—ll, L.L. D., F. R. S.," which is a capital imitation of the style of a certain eminent physicist. The closing paragraphs are as follows:—

"Experiment has proved that the juice of three or four lemons and three-quarters of a pound of loaf sugar, dissolved in about three pints of boiling water, give saporous waves which strike the palate at such intervals that the thrilling acidity of the lemon and the cloying sweetness of the sugar are no longer distinguishable. We have in fact a harmony of saporific notes. The pitch, however, is too low, and to heighten it, we infuse in the boiling water the fragrant yellow rind of one lemon. Here we might pause if the soul of man craved no higher result than lemonade. But to obtain the culminating saporosity of punch, we must dash into the bowl at least a pint of rum and nearly the same volume of brandy. The molecules of alcohol, sugar, and citric acid collide, and an entirely new set of vibrations are produced—tremors to which the dullest palate is attuned.

"In punch, then, we have rhythm within rhythm, and all that philosophy can do is to take kindly to its subtle harmonies. It will depend in some measure upon previous habits, whether the punch when mixed will be taken in excess or in moderation. It may become a dangerous ally of gravity, and bring a sentient being to the gutter. But, on the other hand, it may become the potent inner stimulus of a noble outward life."

Baron Liebig on Bread Making.—In our remarks regarding the use of phosphoric acid in bread making, in the last number of the *Journal*, we omitted to say that while many of the English papers and magazines give the credit of the discovery to Liebig, the great chemist himself distinctly bestows it upon Horsford, to whom it rightfully belongs. More than six months since, he published an article upon bread making in the *Annalen der Chemie und Pharmacie*, in which he makes most flattering allusions to the latter named gentleman. He says, "the phosphoric baking powder of Prof. Horsford in *North America*, I hold to be one of the weightiest and most beneficent inventions which has been made in recent times." This is important praise, coming, as it does, from the greatest living chemist.

We are sorry to see, however, that Liebig like so many foreigners (especially the English) is apparently very loose in his ideas concerning trans-atlantic geography. "*North America*" is a great continent, and it contains a nationality called the "United States," the citizens of which have supplied to the world more important inventions, and made more wonderful discoveries in science and art, than all other nations in the same period of time. The United States is hardly put down on English maps, and when anything remarkable is announced as having occurred here, the English people do not seem to understand it, and proceed to blunder and misstate, until they get others as deep in the fog as themselves. We are willing to pay the expenses of a Yankee schoolmaster to go over to the little islands constituting the "United Kingdom," and teach the English people *geography*.

Patents.—The activity of the Patent Office mill has never been greater than at the present time, as may be inferred from an examination of the grists of patents which are weekly ground out. We entertain the highest respect for inventors, and deeply sympathize with them in the weighty anxieties and labors which rest upon them. We mean by inventors, those who are really such,—those who invent original machines and processes, or improve upon those which are known and understood. All "patent-seekers" are not inventors; neither are all "patent-getters" inventors. The largest part of the patents secured are entirely valueless, and had better never been asked for, or granted. By adroit management, many worthless patents are sold, and tens of thousands of dollars have been lost in patent investments, by unsuspecting, confiding mechanics, farmers, merchants, etc. On the other hand, some that are really valuable, are never brought out to benefit the world, owing to the

poverty or modesty of the inventor. The great patented improvements and inventions, — those which have a high money value,—seldom benefit the discoverer or patentee. The sharpers, moneyed men, or speculators, turn the poor inventor out of court, steal the product of his brain, and seize the wealth which flows from the sale of the improvement. The world is full of "hard cases" of this character, and there is but little hope that justice will overtake the offenders. The patent business, as conducted in this country, has a history, thrilling and instructive, and a large volume would be required to narrate all the "joys and sorrows" that have been experienced by patentees.

THE STUDY OF PRACTICAL SCIENCE. — We have in this country a considerable number of institutions for teaching practical science and art, and also a few which profess to afford assistance and encouragement in prosecuting experiments in science and invention. They are, however, as a class, very far from meeting the great want of the times. Our young men place themselves under instruction in these institutions, and after years of what is called "study" they go out into the world but little better qualified to advance the boundaries of knowledge than before commencing study. The institutions alluded to, some of them at least, need a thorough renovation; a new element must be infused into them. There must be less of the abstract, and more attention given to the practical and useful. Instructors appear to think more of advancing their own interests, and creating a reputation, than of the welfare of their pupils. One half of the professors and instructors are not qualified for the posts they occupy. The chemistry taught in many of the colleges is simply a kind of entertaining pyrotechny, and the gassy lecturer not only fills the lungs of his auditors with gas, but he drowns or suffocates the activities of the brain also, with the agent. If some competent writer or investigator will take hold of this matter and hold up to public gaze the imbecility or incompetency of many of our schools of science, socalled, he will do a good service to the community.

MASS. AGRICULTURAL COLLEGE. — We visited this new institution at Amherst in October, and under the guidance of Prof. Stockbridge, examined the grounds, farm buildings and arrangements for instruction in agricultural science. There are at present one hundred and two students connected with the institution, good, hale, hearty, intelligent looking young men, who, we hope, if they learn how to use the plow and hoe at Amherst, will never relinquish them for pen or sword.

The situation of the farm is indeed beautiful, and the variety of soil, with upland and lowland, is favorable to the growth of all the cereal, root, and grass crops. So far as situation is concerned we doubt if a more favorable place for the location of the college could be found in the Commonwealth. We have some views to express regarding our State institution, and Agricultural Colleges in general, which must be deferred to the next number of the *Journal*.

Seven out of sixty-four fires in New York during the month of August, were caused by *kerosene*. Out of 100 samples of oil tested by the Board of Health, only *one* came up to the legal standard. Manufacturers and dealers are reckless in their violation of the law, and will continue to be so until public sentiment demands its rigid enforcement. The crime ought to be punished as severely as arson.

Hon. S. S. Fisher, U. S. Commissioner of Patents, in a recent address before the American Institute, gives some comical examples of the "Yankee notions" for which patents are sometimes sought. "One man lately wished to patent the application of the Lord's Prayer, repeated in a loud voice, to prevent stammering; another claimed the new and useful attachment of a weight, or other article possessing gravity, to a cow's tail, to prevent her from switching it while milking; another proposed to cure worms by extracting them with a delicate line and a tiny hook baited with a seductive pill; while a lady patented a crimping pin, which she declared might also be used as a paper-cutter, as a skirt supporter, as a paper-file, as a child's pin, as a bouquet-holder, as a shawl fastener, or as a bookmark."

The English Chemical Society has instituted a gold medal in honor of Faraday, to be given to such foreign chemists as shall distinguish themselves in the science.

BOOK NOTICES.

A MANUAL OF ELEMENTARY CHEMISTRY, Theoretical and Practical. By George Fownes, F. R. S., late Professor of Practical Chemistry in University College, London. From the tenth revised and corrected English edition. Edited by Robert Bridges, M. D., Prof. of Chemistry in the Philadelphia College of Pharmacy. Philadelphia: Henry C. Lea.

This is a thoroughly revised and much enlarged edition of a manual which has been very popular as a textbook in our colleges and medical schools. The work of revision, since the death of the author, has been done by Bence Jones and Henry Watts, whose names ought not to have been omitted from the title-page of the American edition. The work has now become quite too large for use as a text-book, but as a compendious work of reference on chemistry it is unquestionably the best now before the public.

A COURSE OF PRACTICAL CHEMISTRY, for the use of Medical Students. By William Odling, M. B., F. R. S. From the Fourth and Revised London Edition. Philadelphia: Henry C. Lea.

This edition of Odling's excellent little manual is considerably improved, especially in the analytical portion; and the new atomic weights and formulæ have been substituted for the old. While making these changes, we are surprised that the author did not likewise adopt the new nomenclature, which is rapidly coming into general use among scientific men.

THE POLYTECHNIC is a new semi-monthly paper, "devoted to the interests of polytechnic and scientific schools and a record and review of civil, mechanical, and mining engineering, and general college news"; published by M. L. Marks, Troy, N. Y. The first two numbers are handsomely printed, and on the whole, are quite promising.

The "Address Commemorative of Reuben D. Mussey, M. D., L. L. D.," delivered by Prof. A. B. Crosby, as an Introductory to the annual session of the Dartmouth Medical College, has been published in a neat pamphlet. It is a just tribute to the memory of a remarkable man.

Messrs. Lindsay and Blakiston's "*Physician's Visiting List,*" for 1870 has been received. This is almost an indispensable annual among physicians, and its merits are well understood.

Dr. S. W. Butler, editor of the Medical and Surgical Reporter, Philadelphia, has ready the *Half Yearly Compendium of the Medical Sciences*, for the half year ending July 1869. It is a very valuable publication, in many respects more desirable and useful than Braithwaite's Retrospect. Both of these semi-annual visitors should be found upon the table of every physician.

☞ *The New York Medical Journal*, a notice of which will be found in our advertising columns, is a journal of high merit and excellence. The editor and the contributors rank among our most distinguished medical men, and each number contains matter which does honor to American medical literature. It is published by D. Appleton & Co., New York.

Medicine and Pharmacy.

RECREATION FOR PHYSICIANS.

No class of men work harder, or bear about from day to day a heavier load of responsibility than physicians. If any laboring or professional man needs recreation, the restless, care-worn physician certainly does, and it is his duty often to break away from his arduous labors and engage in some pursuit or pleasant recreation which will afford rest to mind and body. The mind needs to be switched off from the strictly professional track, in order that its normal, healthy tone may be maintained. Studying disease constantly, and thinking about, and prescribing for ills of every conceivable form and type, tends not only to dwarf the mind, confining it to a single line of thought, but it produces morbid reactions, and sometimes serious mental disturbance. It is almost impossible for the physician to take a "vacation." He can hardly leave home for a longer period than a single day, without provoking the displeasure of some patient or friend, needing his services. If it is deemed impossible to take long seasons of rest, let him take short ones, and take them often. A half day spent in pleasant, social intercourse, or a yacht excursion, or in joining what is known at the North as a "chowder party," will work wonders in the way of recuperating the exhausted energies, and relieving the mind from abnormal tension.

The old Essex North Medical Society of Massachusetts have taken the initiative in introducing the element of recreation into their meetings. A pleasant harbor excursion at Newburyport was enjoyed by the Society in August, and in September they accepted our invitation to meet at "Lakeside Farm," an account of which meeting may be found below, taken from the *Newburyport Herald.* At neither of these meetings was there a "case" described, or any mention made of pills or boluses. Every topic of that kind was ignored, and the hours were devoted to social enjoyment. We believe other medical societies will do well to follow the example of the Essex, and as often as convenient let the members meet together to promote good cheer, to drown selfishness and professional animosities, and above all, to relieve the over-burdened mind of anxiety and care. The physician is not necessarily doomed to an eternal round of professional labor, to a tread-mill the creaking of which must never cease. Let us have a little wholesome recreation, we say.

At the meeting at Lakeside, Dr. Perkins, of Newburyport, made a few sensible remarks regarding the importance of physicians devoting a portion of their time to the investigation of the physical and natural sciences. In this way, a change in the direction of the thoughts is secured, and a healthful reaction results. Besides, it is important that medical men should be familiar with the different departments of science, as they are intimately connected with, or illustrate and throw light upon many of the dark problems in medical science. The physician should be a man of culture, of much general information, in order that he may influence and mould society for its good. It is certain that chemistry is too much neglected by physicians. Experimentally studied, it would prove a kind of healthful recreation, of much benefit to mind and body, and it will be well for physicians when they are led to regard it in this light.

THE DOCTORS AT LAKESIDE.

THE ESSEX NORTH DISTRICT MEDICAL ASSOCIATION held its semi-annual meeting at Haverhill, where the members were entertained by Dr. Nichols. It was the largest meeting the Society has ever had, the presump-

tion being that the fraternity anticipated a good time, from the Dr.'s well known genius in that direction. The host had carriages in waiting at the bridge, which conveyed the party to his residence in the city, where they proceeded to view his garden and grapery. This is alone worth a visit, as illustrating the perfect success of Dr. Nichols' system of special fertilizers, as more vigorous vines and more magnificent clusters of grapes cannot be found in the country. The party then drove to "Lakeside"—the doctor's estate on Lake Kenoza. This embraces a hundred acres of hill and dale, valley and grove, of every variety of soil that is needed on an experimental farm, though it is no longer experimental, for the Dr. has completely established the theory of mineral manures by such success with every variety of crop for a series of years as no farm in these parts ever boasted before. He has this year raised over thirty bushels of wheat to the acre; his corn is acknowledged to be the finest in the country; his beets can't be beat; while his grass land reminds one of the rank growth of the prairies. His reclaimed meadow and his system of drainage are models of scientific farming. But the most interesting feature of the place is the vineyard, which contains seven hundred vines, four years old, which under the Dr.'s skilful manipulation yield their luscious fruit by tons. There are twenty-four varieties in all, fifteen of which were ripe and graced the dinner table.

Old Ike Walton says, "that God could have made a better berry than the strawberry, but doubtless he never did;" so we might say that doubtless he could have made a more beautiful place than Lakeside, but doubtless he never did. Kenoza is a lake of the purest crystal, five miles in circumference, in an emerald setting of hills and groves. The Doctor has civilized the groves, trimming them up and laying out tasteful walks, building seats and tables and all the conveniences for picnic life. He has a picturesque stone house on the beach and a wooden cottage, at some little distance in the grove. These are within a quarter of a mile of the farm house, and ten minutes' drive of his town house. Fine yachts and row-boats, which are duly provided with boat houses and wharves, leave nothing to be desired in the way of rustication.

About two o'clock the company returned from their strolls and farm inspection with appetites to do justice to a dinner that was in perfect keeping with everything else about "Lakeside." Our former experience at one of these doctors' meetings taught us that the profession loved good living themselves, whatever they may allow their patients, and Dr. Nichols was evidently aware of the tastes of his visitors. From the savory chowder, through all the courses of salads, meats, sweets and ices, to the great piles of pears, peaches, and grapes, beautifully set off with flowers, that constituted the dessert, everything was simply perfection. As to the coffee, cigars, etc., they were pluperfect.

Dinner over, the Society was called to order by Dr. Lamb, of Lawrence, President. Dr. Root, of Byfield, Secretary and Treasurer, read the report of the last meeting, which our readers will recollect was out in our harbor. Speeches were then made by Dr. Perkins, of this city; Surgeon-General Dale; Dr. Nichols; Dr. Jeremiah Spofford, of Groveland, the veteran of the Society; Dr. Sargent, of Andover; Dr. E. G. Kelley, of this city, and others. A vote of thanks was passed to Dr. Nichols for his kind reception and bounteous hospitality. An invitation was then given the Society by Dr. Kittredge and Surgeon-General Dale, to become their guests at Andover at the next meeting in January, which was duly accepted. The meeting then adjourned, and the rest of the afternoon was devoted to sailing, fishing, and rambling round, *ad libitum*. A better company and a better time we never want to see. —*Newburyport Herald, October 1st.*

SOPHISTICATIONS IN DRUGS.

In a former issue of the *Journal*, we had something to say regarding adulterations in articles of food, and promised to consider at another time the subject of adulterations in drugs and medicines.

As regards medicines, it is not unreasonable to assume that there are some physicians, who have been in practice ten, perhaps twenty years, who have never employed but few, if any, remedial substances of perfect purity, or those of the highest integrity. The doubt or suspicion with which many physicians regard all medicinal agents, arises from disappointments met with in their employment, and these provoking failures are due, in a great measure, to the bad character of the substances employed. It is impossible for medical men to realize the extent of the falsifications practiced in drugs. The shops are crowded with inert and factitious substances. In medicinal effect, the difference is immense between pure and commercial glycerine, between pure and commercial essential oils, copaiva balsam, olive oil, senna, gums,—in fact all unmanufactured and manufactured substances. The *cheap*, *commercial* articles are what go into the saddlebags of country physicians, and oftener than is suspected into the prescriptions of those in the city. The close competition in trade existing between jobbers and importers of drugs in cities, leads to extraordinary and persistent falsification. This deplorable competition extends into the shops of dispensing druggists and the prominent end is to secure *cheap* drugs, *quality* being too often a secondary consideration. A country druggist going to the city to purchase medicines, is naturally desirous of procuring them at the lowest rates possible. He has a list of wants, which he submits to the "pricing process" among the jobbers, and the party who names the lowest prices secures the order. At all points in the United States *competition* among wholesale druggists and jobbers was never greater than at the present time, and the stream of evils which flows from it was never so mischievous in its influence.

In an interview with a wholesale drug dealer of high respectability, who failed in business several years since, he attributed the failure to the attempt, on his part, to supply or sell only such drugs as were of known purity and excellence. He was confident the demand on the part of the trade for that class of goods was not sufficient, in a city of a quarter of a million inhabitants, to sustain a single dealer.

The falsification of drugs is not alone confined to the more costly substances, but extends to those which are common and low priced. Our medical readers will be astonished to learn that a drug so cheap as the sulphate of magnesia (Epsom salts) is *cheapened* and extended by the admixture of common salt, sulphate of lime, sulphate of soda, etc., to a large extent. We recently saw in the warehouse of a dealer, in one of our large cities, a huge pile of barrels filled with "salts" of this character, which were being sold rapidly to the trade, at *half a cent* less per pound than the true article. In physical appearance they would be satisfactory to physicians and consumers. But it is unnecessary to dwell upon the fact that drugs are largely sophisticated. This is a matter generally admitted and understood by dealers and prescribers. The inquiry arises "What is the remedy?" The remedy for the evil is in the hands of those most directly interested in its abatement. It is clear to us that physicians alone can so far remove the evil as to be able to protect themselves, and do much towards preventing the general sale of spurious or attenuated medicinal substances in the community.

To reach this end, two requisites on their part are necessary; first, a competent knowledge of the true character of medicines. Every physician should be able to know from physical appearances or chemical tests, what substances are pure and what are spurious; and, second, with this knowledge, he should possess the independence and courage to inspect rigidly the stocks of those through whom he is supplied with remedies and reject all that are impure, or that are of a suspicious character. Chemistry and Pharmacy do not receive that attention in our medical colleges which their importance demands.

The trouble is, physicians are oftentimes not competent judges of the quality of medicinal agents; they are compelled to trust to the statements of dealers and dispensers; and the venders, in turn, are as much in need of therapeutical knowledge as prescribers. It would be well for every medical association in the country to have specimens of all important therapeutical agents, which are of known integrity and purity, and retain them for the inspection and study of the members of the society at their meetings. This would familiarize the members with the appearance of pure drugs, and do much towards enabling them to detect factitious substances in the market.

BROWN-SÉQUARD ON EPILEPSY.

Brown-Séquard, for whom a Professorship of Experimental Medicine has just been created at Paris, has been lecturing upon epilepsy. He hopes that his experiments may bring to light the means of a cure for this disease, —in some of its forms, at least. It is certain that he can produce epilepsy in some animals, not only by a lesion of the nervous centres, which have been generally considered the exclusive seat of the malady, but also by peripheric irritations.

He showed to his class a dozen or more Guinea pigs which had suffered a section of a lateral half of the spinal cord from one to six months ago. These animals were not merely spontaneously epileptic, in consequence of this mutilation, but the epileptic attacks, which lasted from thirty to sixty seconds, could also be provoked at the will of the experimenter. In order to produce them, it is necessary to irritate a certain portion of the body, to which Brown-Séquard has given the name of *zone épileptogène*. This zone includes the skin of the lateral part of the face and neck, animated by the third and fourth pairs of cervical and the fifth pair of cranial nerves. The irritation of no other part of the body is attended by the same results. If the spinal cord has been cut on the left side, the epileptic zone of the opposite side must be pinched. It is a remarkable fact that the irritation of the nervous centres themselves which supply this zone, does not disturb the animal in the least. The same phenomena show themselves, if, instead of the hemisection of the spinal cord, a section of the great sciatic of the thigh is made. Indeed, the epileptic attack is even more violent.

Another remarkable fact is the loss of sensibility in the epileptic zone after hemisection of the spinal cord and if, by means of a caustic or the hot iron, the skin of this region be destroyed, so as to form an eschar, the animal is cured of the epilepsy, and both the spontaneous and the provoked attacks cease at once.

The cervical ganglia of the sympathetic nerve play an important part in epilepsy. The pallor of the face, which is almost a constant initiatory symptom of the attack, is produced by the contractions of the vessels of the face which are under the control of nerves emanating from these ganglia.

The dilatation of the pupil of the eye, which is the second most frequent symptom, is produced by a contraction of the vessels at the base of the brain, also under the control of these ganglia. These phenomena can be demonstrated upon the epileptic animals used in the experiments.

Further investigations in this new direction will be awaited with great interest by all medical men. Some of Brown-Séquard's epileptic rabbits have already been taken to England, where they have attracted a good deal of attention.

THE SPECTROSCOPE IN PHARMACY.

English chemists have been experimenting with the spectroscope upon the solutions of substances used in pharmacy. When light is allowed to pass through a solution, it is partly absorbed, giving rise to shadow-like bands, called *absorption bands*. These bands are constant and give a *spectrum peculiar to each preparation.*

Many substances which form merely colorless solutions (as the salts of manganese, for example) afford, nevertheless, very strong absorption bands.

The strength of the solution under examination must be carefully graduated. If it is too strong, too much light will be absorbed, and the bands will be large, cloudy, and obscure. The liquid may be diluted by degrees until the spectrum is most advantageously seen. As the dilution proceeds, the finest and faintest lines disappear, and afterwards the darkest. A few trials will soon enable one to decide upon the degree of strength best for the purpose.

Some of the spectra of medicinal preparations (as Tinct. Hyoscyami, Tinct. Cannab. Ind., etc.) are extremely beautiful, vying with those of any of the mineral salts commonly used as objects for exhibition.

This spectroscopic examination promises to be an effective means of detecting adulterations and substitutions; for hardly ever do the spectra of any two articles appear exactly the same. The smallest discrepancy is immediately seen when the spectra are placed side by side, by means of an additional prism.

The process will also be an aid in many analytical researches, since the several constituents of a mixture may often be detected by the peculiarities of their spectra. Thus, cochineal may be at once detected in Tinct. Cardam. Co. and Tinct. Cinchon. Co. The coloring matter of blood will show its own bands when mixed with cochineal. The spectrum of a tincture made with the leaves of the biennial henbane differs entirely from that of the annual.

The geologist often has occasion to determine whether a clay contains the protoxide or the peroxide of iron, or both. Spectral analysis will settle the question at once, and point out the protoxide, peroxide, or magnetic oxide.

On the whole, this new field of spectral analysis is likely to prove very interesting, and one of great importance from its practical applications.

PRUSSIC ACID.

We learn from the *Journal des Connaissances Medicales* that, at the last sitting of the French Academy of Medicine, Dr. Scoutettenn communicated the substance of an essay which created quite a sensation. It was a posthumous disquisition on hydrocyanic acid, found among the papers of the late celebrated Professor Schönbein, of Basle. The question discussed was, whether there was a test for the above mentioned liquid besides those of M. Liebig and M. Buignet, which, within certain limits, may reveal the presence of prussic acid, but are insufficient to fix its quantity and detect a crime with certainty. Professor Schönbein then proceeds to describe a reagent discovered by himself, and delicate enough to bring out to view even the millionth part of a drop, whether diluted with water, or vaporized in the air; a circumstance affording new proof of the incalculable divisibility of matter. Dr. Scoutettenn, who lives at Metz, announced, in his communication, that he had repeated the late Professor Schönbein's experiments, with the aid of two chemists, MM. Guebin and Pont, and that he begged to submit some of the test-paper prepared by himself to the Academy for further trial. The specimen forwarded was of the kind called filtering paper, and had been soaked in a solution of three gms. of guaiacum resin in 100 gms. of alcohol. To use it, a solution of ten decigr. of sulphate of copper in fifty gms. of distilled water, should be made, and the paper, which is white, cut into narrow slips. One of the latter being wetted with the solution, it is then exposed to the action of the minute quantity of hydrocyanic acid dissolved in water, and suspended in the air; the paper will then instantly turn blue. Dr. Scoutettenn remarks that these slips of paper will be useful in examining the quality of the medicinal waters or syrups containing a very small quantity of the acid. The paper need only be placed on the unstoppered neck of the phial containing the medicine, and the blue color will at once become visible. Various other experiments are described, all tending to the same result.

NEW TESTS FOR BLOOD-STAINS.

Prof. Bloxam has found that a mixture of tincture of guaiacum and ozonized ether (that is, a solution of peroxide of hydrogen in ether) instantly produces, with blood or blood-stains, a beautiful blue tint. Prof. B., in the case of a stain twenty years old, extracted a single linen fibre with an almost inappreciable amount of the stain upon it; and on subjecting it to this test, the blue color was readily distinguished through the microscope.

The spectroscope may also be employed as an extremely delicate test for blood-stains. Mr. Sorby has shown that the one-thousandth part of a grain of the red coloring matter of the blood may be thus detected with the greatest certainty.

APOMORPHIA.

Dr. Matthiessen, the celebrated chemist, in his investigation of the opium alkaloids, has found that by the action of muriatic acid on morphia, a new base is produced, which, in its composition, differs from morphia by the removal of one equivalent of water. Its physiological action, however, is wholly different from that of morphia. It is free from narcotic properties, but acts as a powerful emetic, the action of which is not followed by injurious effects. It seems likely to become a valuable medicinal agent.

Recipe for Burns.—Make a saturated solution of alum (4 oz. in a quart of hot water). Dip a cotton cloth in this solution and apply immediately on the burn. As soon as it becomes hot or dry, replace it by another and continue doing so as often as the cloth dries, which at first will be every few minutes. The pain will immediately cease, and after twenty-four hours of this treatment the burn will be healed, especially if commenced before blisters are formed. The astringent and drying qualities of the alum will entirely prevent their formation. The deepest burns, such as those caused by boiling water, drops of melted metal, phosphorus, gunpowder, fulminating powder, etc., all have been cured by this specific.

Dr. Cameron, a Dublin chemist, has been experimenting on the milk of the sow, and has shown that it contains 18 per cent of nutritious matter, while human milk contains but 11 per cent. The relative nutritive values of different kinds of milk may be thus arranged in an increasing order: human milk, cow's, goat's, ewe's, mare's, ass's, and sow's. This accounts for the rapid growth of young pigs compared with other animals.

Dr. Demarquay, of Paris, has recently performed the difficult operation of removing the greater part of the tongue. The patient had suffered from a disease in this organ for more than twenty years. The operation was perfectly successful, and the patient is now able to articulate quite easily and correctly, notwithstanding the loss he has sustained.

French chemists have proved that fruits,—as apples, cherries, currants, etc.,—after being gathered, begin to absorb oxygen and give off carbonic acid. They give many details of their experiments; as, for instance, that 5 apples, weighing together 348 grammes, yielded, between the 19th of January and the 15th of July, 6,648 cubic centimetres of carbonic acid.

Dr. Magni, Professor of Ophthalmology in the University of Bologna, has gone to Lima, Peru, to operate on a merchant for cataract. His fee is to be 100,000 francs (about 20,000 dollars in gold), besides the expenses of himself and assistant.

DETECTION OF BLOOD STAINS.

Dr. Richardson, in the *American Journal of Medical Science*, speaking of this subject, says:

Through the courtesy of Dr. Linderman, Director, and Mr. J. R. Eckfelt, Chief Assayer of the United States Mint, I was enabled to estimate the delicacy of the microscopic test for blood, as follows: Upon a square of waxed paper determined by Mr. Eckfelt, on the accurate balance used for the National Assays, to weigh exactly 48 milligrammes, I made twenty dots of fresh blood from my finger, which, when dry, added .4 of a milligramme to the original weight, and consequently were each on an average equivalent to about .02 of a milligramme, or 1-3200 of a troy grain nearly. The fourth part of one of these spots, weighing of course in round numbers 1-12000 of a grain, was detached with the point of a cataract needle, and when moistened under the 1-25 showed many hundred well-defined red blood corpuscles; ten circular ones among them, measured with the micrometer, averaged 1-3494 of an inch in diameter, and could, therefore, by this criterion of superior size alone, be diagnosticated from the corpuscles of an ox, sheep, or pig, with the same feeling of certainty with which any surgeon could testify that a perforation of the skull only half an inch across could not possibly have been made by any bullet measuring an inch in diameter.

The Race.—The Harvard and Oxford boat race is the subject of an editorial in the London *Lancet*. That journal states that if the diet-scale of the Harvard crew had been really such as was reported, the physical powers and the health of the Americans would have been seriously affected. On inquiry it appears that the Harvard men, while training, were allowed plenty of meat, with milk, rice, vegetables, and fruit, and that their dietary differed from that of their opponents in the matter of beer. The Americans used no beer, wine, or spirits. The *Lancet* says that it cannot express an opinion on the influence of the rowing or steering of the two boats, or on the effect of the want of experience in the Harvard men of the currents of the Thames, but that the difference in diet had clearly no effect on the result, and concludes as follows: "The crews were well matched, the race was most severely contested, and it is evident that the Oxonians had to put forth their full powers to make the victory theirs."

Medical Education.—The following authentic copy of an official document has been sent to the *Medical and Surgical Reporter*, from one of the counties of Pennsylvania. We recommend it as a model form:

Post Mortem. —— day of July, 1869.
Alexander Montgomery, deceased; found upper portion of Oss Frontalis lacerated and entirely Anti-Anastimose, also the Ossa Parietals, for half way back toward the Oss Occipital Anti-Anastimose, the entire wound being immediately along the coronal suture; from internal examination found buried deep in the Cerebrum two pieces of Stone which I removed therefrom.

—— ——, M. D.

The whole of the above I certify to being true and correct.

Paste.—The following is a recipe for making common paste which will keep for a long time without fermentation:

Dissolve an ounce of alum in a quart of water warmed; when cold add as much flour as will give it the consistence of cream; then strew into it as much powdered rosin as will lie on a shilling, and two or three cloves, ground. It will keep for a year, and when dry may be softened with water.

Various stories of fatal cases of poisoning by wearing stockings and other articles dyed with *coralline red*, have appeared in foreign papers, and have been reprinted here. M. Guyot, in the *Comptes Rendus* of Aug. 6, 1869, gives the results of an exhaustive series of experiments, which prove that coralline is not a poison, whether taken internally even in large doses, or infused directly into the blood.

DEPOT IN NEW YORK, 71 WILLIAM STREET, ... NICHOLS & HOADLEY, Agents.

PRICE-CURRENT.

JAMES R. NICHOLS & COMPANY,

Manufacturers of Standard and Special Chemicals,

No. 150 Congress Street, BOSTON.

JAMES R. NICHOLS.
CHARLES E. BILLINGS.
ALBION R. CLAPP.

[LABORATORY ESTABLISHED 1857.]

NOV. 1, 1869.

TERMS, NET CASH. Bank Draft or P. O. Money-Order to accompany the order.

For the convenience of small dealers, we present below prices of our chemical products, in small quantities, such as are often wanted. For prices in packages, or in large quantities, see our regular monthly Price-List.

PRICES OF VIALS AND BOTTLES.—g.s.v., means glass-stoppered vial, the price of which is 10 cents, more or less; c.v., corked vial, 6 cents, more or less; c.b., corked bottle, 12 cents, more or less; g.s.b., glass-stoppered bottle, 18 cents, more or less. The cost of the bottles and vials as given is to be added to the price of the articles in all cases. In remitting cash for goods, remember to include price of package as per list below.

OF
CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. IV.—No. 6. BOSTON, DECEMBER 1, 1869. FIFTY CENTS PER ANNUM. SINGLE NUMBERS, SIX CENTS.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.
RECEIPTS.—A receipted bill will be sent by return mail to any subscriber who will enclose with his subscription a three-cent postage stamp, for return postage.
A list of premiums is offered to those who obtain subscribers.

Contents.

Familiar Science.

EVAPORATING WATER IN CONNECTION WITH STOVES AND FURNACES.

THE readers of the JOURNAL are cognizant of the fact, that we have uniformly opposed the practice of evaporating large quantities of water upon stoves and in furnaces, on the ground that it was not conducive to health or comfort. The views expressed have not met with the approval of some writers, whose opinions we are accustomed to regard with deference and respect. We do not, however, upon a careful consideration of the whole subject, and from a repetition of experiments undertaken many years since, see any reason for changing or modifying the views expressed. There is a popular impression, hard to be eradicated, that stoves and furnaces *dry the air* which comes in contact with them. Air furnaces are constantly spoken against, because they *dry* or "burn up" the air and render it unhealthy to the occupants of dwellings. This is an error. Atmospheric air cannot be "dried up or burned up" by any heating apparatus in use at the present time. Heated air has a larger capacity to hold vapor than cold air, but none of its natural moisture is expelled from it by heat. A cubic foot of air at 10° Fahrenheit above zero, in winter, retains 1.11 grains of water; if it is allowed to flow through the air-box leading to a furnace, and thereby becomes heated, it still holds 1.11 grains of water, after reaching the interior of dwellings. If the temperature is raised to 70° Fahrenheit, it is capable of holding 8 grains to the foot. By heating air, no moisture is driven out, but the capacity to hold it is simply increased, and if we supply vapor, it will seize and hold it so long as the temperature is maintained. Air is said to be *saturated*, when it holds all the water it is capable of, and this capability of holding water depends upon the amount of heat that is combined with it. The hotter air is, the drier it appears. The reason why a furnace injudiciously managed appears to dry the air more than one well managed, is that the temperature is higher, and the air is thus rendered capable of retaining more vapor. Undue heat, then, proceeding from stoves and furnaces, gives rise to certain impressions which are best expressed by the word *dry*, and in order to remove or mitigate the evil, we place pans of water in connection with the source of heat and allow it to evaporate. Is this practice a good one?

To answer this question affirmatively we are required to believe that air admitted to our rooms in winter, heated to a point capable of affording comfort, say 70° Fahrenheit, is abnormal and needs to be interfered with, or saturated with moisture. This we do not believe. For fifteen years we have maintained in our dwelling in cold weather a uniform temperature, ranging between 65 and 70° Fahrenheit, and during that time not a drop of water has been evaporated, and scarcely an instance of illness has occurred. No *sensation of dryness* has been complained of by members of the family or by visitors. On the other hand, a delightful feeling of *comfort* is participated in by every one; there is no lassitude, no nervous uneasiness, no parched condition of the skin, or other unpleasant symptoms. The heat proceeds from coils of iron pipe heated by steam. The steam in the pipes never exceeds a temperature of 212°, as the boiler pressure cannot go higher than two pounds to the inch. The air that impinges upon these pipes, while in immediate contact, is heated to at least 100° Fahrenheit, but as soon as diffused, falls to the general temperature of about 70° Fahrenheit.

Now, it matters not what the source of heat is, the air is rendered no drier by passing around the fire pot of a furnace than by passing over steam pipes. Indeed, a room heated to 70° Fahrenheit by air which has passed over red-hot iron plates contains as much moisture as one of that temperature warmed by hot water or steam pipes. A temperature of 65 or 70° is a normal, healthful temperature, and contains all the moisture needed to secure the highest health.

The trouble is, most housekeepers maintain too high temperature in their rooms; the air is unduly heated, and hence arises the intolerable sensation of dryness. This sensation can be, and often is, produced in dwellings by high pressure steam. Air heated to 80 or 85° produces very different physiological effects from that of 70°. A rise of 2 or 3° in a room is noticed by those who are accustomed to a uniform temperature of 70° or a few degrees below, and a sensation of uneasiness is produced. The great advantage of low pressure steam is, that by its employment we are able to *avoid high temperatures*. With a boiler pressure just sufficient to drive the vapor through the coils, a perfectly uniform heat is maintained. Once regulated, it needs but little interference or care. The use of steam or hot water imparts no *moisture* to the air of dwellings; not an atom is allowed to escape from a well arranged apparatus.

Many times every winter, neighbors and friends on coming into our dwelling remark, "how delightfully *moist* and pure the air is, so different from *furnace* heat!" The erroneous idea is entertained that *steam* heat supplies *moisture* to the rooms.

If the heat of dwellings is kept at a normal standard, the warm air contains all the moisture needed for health or comfort. If the temperature is abnormally high, we do not believe the train of evils which follow are avoided by vaporizing large quantities of water. We have known of several pailfuls of water being evaporated every day in furnaces, and upon going into rooms have heard the peculiar noise occasioned by the ebullition of water in the furnace below. In such families there have been uniformly more catarrhal difficulties, more rheumatism, more headache, than in other houses where no evaporation is allowed. This subject is so important, that we shall continue the discussion in a future issue of the JOURNAL.

HOW TO DO FOR SICK PEOPLE.

The following directions for preparing articles of food etc., for the sick, are distributed through the Hospital for Incurables, Philadelphia. The methods given are so excellent and reliable, that we are led to present them to the readers of the Journal. It will be well for the reader to preserve the paper for reference in time of sickness.

BOILED RICE.

Most readers think this is something easily prepared. So it is perhaps, but few nurses have an idea of the necessity of having it properly done; that is, cooking it until every grain becomes perfectly *softened.* If the grains are not reduced to this soft state, rice is almost certain, when swallowed, to irritate the digestive organs, and instead of soothing the parts and sustaining strength, will actually produce a diarrhœa, etc. This has been frequently noticed in hospitals.

When properly boiled until each particle becomes so softened that the *grain* cannot be detected when eaten, there are few articles of diet for the sick which can be made more acceptable to the taste of invalids than boiled rice.

CORN STARCH.

To one tablespoonful of corn starch add enough cold water or cold milk to make a perfectly smooth paste. Then pour this into half a pint of boiling milk and carefully boil a few minutes, stirring it all the time, and putting in a little salt. Sweeten to the taste, and add any essence or spice liked by the person who is sick. Then set aside to cool.

This, like everything else which contains milk, requires great care to prevent it from scorching, and the least of it can be observed by the person for whom prepared. For this reason a sauce-pan with thick sides is usually preferred, and the heat should always be applied to the bottom of the vessel. In stirring be cautious not to splash against the sides of the utensil more than can be helped.

ARROW-ROOT.

Take a tablespoonful of arrow-root, and mix it with enough cold water to make a paste free from lumps. Pour this slowly into half a pint of boiling water, and let it simmer awhile until it becomes thick and jelly-like; sweeten to the taste, and add a little nutmeg or cinnamon. Instead of the half pint of boiling water, the same quantity of boiling milk, or half milk and half water, may be used. This will make it more nutritious.

OATMEAL GRUEL.

Mix a tablespoonful of oatmeal with a little cold water until it makes a smooth paste; pour this gradually into a pint of boiling water, and boil slowly for twentyor thirty minutes, stirring it all the time, and being very careful not to let it scorch in the least. Salt, spice, and wine or brandy should be added to it, unless there is some good reason for not doing so.

PANADO.

Take a slice of wheat bread, break into fragments, and sprinkle over it a teaspoonful of ground cinnamon; put into a cup, pour on it a pint of boiling water, and boil a few minutes until well mixed, when some sugar with a little grated nutmeg must be added. If desirable, a piece of butter may be put in, and also some wine or brandy.

BARLEY WATER.

Take nearly an ounce of pearl barley and wash it well. Then pour on it a pint of boiling water, and carefully boil to one-half. Strain the liquid through a towel, then add some sugar and lemon juice. A small piece of orange or lemon-peel, dropped in while boiling, makes it more acceptable to many persons.

CURRANT JELLY WATER.

A tablespoonful of currant jelly thoroughly mixed through half a pint of cold water.

A sick person may drink as much as wished of this acid water. As with all other drinks for the sick, a little at a time and often repeated is the way it should be given.

TOAST-WATER.

Carefully remove the crust from a slice of stale bread, and toast the slice through on both sides, but do not burn it. Break the slice into three or four pieces, and put them into a pitcher with a small piece of orange or lemon-peel. Pour on a pint of boiling water, cover up with a napkin, and, when cold, strain off the water for use.

It should be freshly made, especially in warm weather.

TOAST SOUP.

Take a thin slice of stale wheat bread, and toast until it is brown through and through; but be careful that you do not burn it. While it is still hot, spread some butter over it, but no more than will strike into the bread without leaving any on the surface. Now break it into fragments; put the pieces into a pitcher, and pour on rather more than half a pint of boiling water. A little pepper and salt improves the taste; so they may be added.

This drink is usually found very acceptable to sick or delicate persons, and, at the same time, quite nutritious. It was much recommended under the name of "toast soup," by the late Dr. William Darrach, of this city, and gave satisfaction wherever used.

WINE-WHEY.

Put half a pint of sweet milk over the fire, and, as soon as it begins to boil, slowly pour into it a wineglass of sherry wine mixed with a teaspoonful of sugar. Grate into it a little nutmeg, and, as soon as it comes to a boil again, remove it from the fire. When cool, strain for use.

BRANDY.

When brandy is ordered for a sick child, it is meant that a few drops, according to the age, should be given in water or some sweet milk, as often as the condition of the patient requires it. Unless told to do otherwise, keep it in reserve for the time of the day when the sufferer appears to exhibit signs of being weaker than usual, and then give enough to restore it to its average condition in health, trying not to get *above* that. Usually it is more frequently needed in the latter part of the day, or quite early in the morning, than at other times.

MILK PUNCH.

Pour two tablespoonfuls of good brandy into six tablespoonfuls of sweet milk and add two teaspoonfuls of ground loaf sugar. Grate some nutmeg into it, and the punch is ready for use.

An adult person can take a tablespoonful of this every two or three hours, but for infants or children you must remember that *one-fourth* of it is brandy. Milk punch is much ordered by physicians for people who have low fevers and for those who are debilitated.

BRANDY, EGG, AND MILK.

Take a fresh egg; break it; separate the yolk from the white, and whip each with a fork until it becomes a froth. Then thoroughly mix them together, and add enough good milk or ordinary cream, well sweetened with finely ground loaf sugar, to make a tumblerful. Next, pour in a tablespoonful of good brandy; if this is not convenient, a proportional quantity of the best whiskey may be used instead. See again that it is well mixed with a fork, when it will be ready for the sick person. A little grated nutmeg added improves the taste for some people.

ESSENCE OF BEEF.

Take a pound of fresh beef, as free as possible from fat; cut it up into very small pieces, or, what is better, shred it with a fork. Sprinkle over it a little salt, and put the meat into a stout stone bottle, such as mead or Scotch ale comes in; cork tightly and tie the cork down with a string. The cork is usually not put in until steam begins to escape from the bottle. Stand the bottle in a vessel of cold water, which should slowly be brought up to the boiling point, and kept at it for at least four hours. To prevent the bottle from breaking against the side of the vessel, by the movement of the boiling water, it should be secured by a piece of cord. Strain through a piece of coarse linen; then let the liquid stand awhile in a cup, and, with a spoon, carefully skim off any fat which may have arisen to the surface. It may be seasoned to the taste with pepper and salt.

The liquid obtained in this manner is one of the most agreeable and highly nutritious articles of diet which can be prepared for the sick.

THE STUDY OF NATURE WITHIN CITY WALLS.

We associate the study of nature with the country rather than the city. The brick walls and stone pavements, the dusty, smoky atmosphere, the noise and confusion of a great metropolis, appear anything but favorable to the pursuits of the naturalist. But even amid such unpromising surroundings he may carry on for years his investigations in the animal and the vegetable worlds, and may add largely to our knowledge of bird and insect, of herb and flower. We cannot better illustrate this study of nature under seemingly insuperable difficulties, than by translating from a lively French writer, the following account of what has been done in this way, even within the walls of Paris:

"One need not go far to study natural history. Even in Paris one may have all nature in a little corner. Did Méry leave the city to write his *Comédie des Animaux?* He wrote it in his lodgings in Paris, and his observations were made in his own rooms. The rat, which plays one of the principal parts, was one of his neighbors in the vacant lots of the *rue St. Georges*, about 1840. . . . Théophile Gautier, in his last fascinating book in which he describes his *Ménagerie*, was at no greater expense in travelling. With his dogs and his cats, his aviary and his monkeys, he wrote at home a volume of humor and experience, which long-winded lecturers on natural history may now look down upon with contempt, but which they will not disdain one of these days. Bernardin de St. Pierre needed only the strawberry vine which grew on his window-sill, to discover a whole world. L'Héritier de Brutéle, one of the botanists whom Cuvier most esteemed and praised, did not go beyond the *Place Vendôme*, to make some of his most curious observations. He was a clerk in the Ministry of Justice during the Directory — a period when many people were away from the city, and still fewer carriages were to be seen, so that wild weeds were at full liberty to grow between the stones of the square. He studied these weeds with the minutest, most microscopic attention. The mansions of the Place Vendôme were almost untenanted, and utterly out of repair. Their fronts were cracked and mouldy, but on these mouldy places mosses grew, and in the crevices were lichens and byssus, a rich harvest for the quill-driving botanist. He studied even the blackening color on the walls, and made the discovery that it was

due to a microscopic lichen. After a year of study, he had a complete herbal, in which surprises were not wanting. He had found in the heart of Paris, between two paving-stones of his dear square, herbs known only in the desert, whose seeds had been tossed hither by some wild African wind. Proud of this herbal, gathered where least likely to be found, he made it the subject of a little treatise, prepared with the greatest care, to which he gave the title of "The Flora of the Place Vendôme." Unfortunately it was not published, and I believe it has been lost since his death.

Another learned man, Dureau de la Malle, without leaving Paris, made the song of birds his especial study. That he might lose nothing of it amid the city noises, he made his observations in the early morning, when the town was asleep. He did not merely consider the music of the song, and how it varied in different species, but he attempted to discover and note with the greatest precision the time of year when it is first heard, and the hour of the day when the first note is uttered. He succeeded in doing this, and made himself a sort of alarm-clock of bird music, which no work of man's hands could equal in regularity and sweetness. He literally found, as Victor Hugo has said, that "the grave voice of the hours was changed into joyous song." The house where he lived in the *rue de la Rochefoucauld*, had a garden with trees enough to lodge all the families of its songsters, and with a soil moist enough for the quail to lay and hatch in it. . . . He went to bed regularly at seven o'clock, P. M., and rose at midnight. His study looked out on the garden, and in mild weather he opened all his windows that he might catch the first murmurs from the nests, the first trills which warbled in the bushes. Bending over his archæological studies, he was better on the watch for this awakening of song than poet or morning shepherd. I never open his excellent work on "The Political Economy of the Romans," without thinking of these concerts amid the leaves, of this music of the dawn, which his learning had for accompaniment as it delved in antiquity."

ACID RIVERS.—The *Rio Vinaigre*, in South America, has its source nearly two miles above the level of the sea on the volcano named the *Purace*. Humboldt was the first to ascertain that its waters contain free sulphuric and muriatic acids. According to Boussingault, this river empties into the Rio Cauca, into which it falls from a height of about 400 feet, discharging daily 34,784 cubic metres of water, containing 37,611 kilogrammes (more than 40 *tons*) of strong sulphuric acid and 31,654 kilogrammes (nearly 35 tons) of strong muriatic acid. No fish are found in the Rio Cauca for more than 10 miles below the point where it receives these acid waters.

In the island of Java there are several small streams and lakes which contain free sulphuric and muriatic acids; and on the island of Sumatra there is a lake which contains free nitric acid. All these phenomena are the result of volcanic action.

THE WONDERS OF AN ATOM.—All things visible around us are aggregations of atoms. From particles of dust, which under the microscope could scarcely be distinguished one from the other, are all the varied forms of nature created. This grain of dust, this particle of sand, has strange properties and powers. Science has discovered some, but still more truths are hidden within this irregular molecule of matter which we now survey than even philosophy dares dream of. How strangely it obeys the impulses of heat—mysterious are the influences of light upon it—electricity wonderfully excites it—and still more curious is the manner in which it obeys the magic of chemical force. These are phenomena which we have seen; we know them, and we can reproduce them at our pleasure. We have advanced a little way into the secrets of nature, and from the spot we have gained we look forward with a vision somewhat brightened by our task; but we discover so much to be yet unknown, that we learn another truth,—our vast ignorance of many things relating to this grain of dust.

It gathers around it other particles; they cling together, and each acting upon every other one, and all of them arranging themselves around the little centre, according to some law, a beautiful crystal results, the geometric perfection of its form being a source of admiration.

It exerts some other powers, and atom adhering to atom, obeying the influence of many external radiant forces, undergoes inexplicable changes; and the same dust which we find forming the diamond aggregates into the lordly tree, blends to produce the graceful, scented, and richly-painted flower, and combines to yield the luxury of fruit.

It quickens with yet undiscovered energies; it moves with life; dust and vital force combine; blood and bone, nerve and muscle, result from the combination. Forces which we cannot, by the utmost refinements of our philosophy, detect, direct the whole, and from the same dust which formed the rock, and grew in the tree, is produced a living and a breathing thing, capable of receiving a divine illumination, of bearing in its new state the gladness and the glory of a soul.—*Hunt's Poetry of Science*. .

COUNTRY AIR AND CITY AIR.—M. Houzeau has demonstrated that the air of the country differs remarkably from that of a great city. The former is strongly disinfectant, has a far greater bleaching power, and, especially after the fall of rain, has a decidedly more marked effect upon bright and oxidizable colors. All kinds of woven fabrics—linen, cotton, or woollen—are much more rapidly bleached in the country than in the city, even when the exposure to air and sunlight is precisely the same. It is likewise true that under the influence of country air many dyed tissues fade sooner; and that iron, steel, and even copper, become more quickly rusted.

TO SHOW THAT AIR HAS WEIGHT.—Teachers, and others who may wish to show the weight of air without the air-pump, can do it by the following simple experiment:—

Boil a little water in a flask to expel the air, then cork the flask tightly, let it cool, and weigh it carefully. Then remove the cork to admit air, and weigh it again, including the cork. The difference in weight will be perceptible with a good balance of the ordinary construction.

THE LEVEL OF THE MEDITERRANEAN AND RED SEAS.—During the celebrated Egyptian campaign of 1798, the difference of level between these two seas was calculated by the French engineers, and found to be .85 of a metre. The result obtained in making the survey for the construction of the Suez Canal, in 1866, was .86 of a metre. The accuracy of the earlier survey is very strikingly confirmed by the close coincidence of these results. They differ by less than 1-25 of an inch.

IS THERE ANY HEAT IN MOOONLIGHT?—The *Comptes Rendus* of September 20, gives a paper on this subject from the pen of M. Marié-Davy. According to the very accurate researches and experimental observations of this author, the heating power of the lunar rays is incapable of affecting by the one-millionth part of a degree, a very sensitive air-thermometer coated with lampblack. This result disagrees with that obtained by Lord Rosse.

ARTIFICIAL LIGHT.—The German chemist, Landsberg, says that artificial light contains 90 per cent of calorific rays, while sunlight contains only 50. To this difference he ascribes the disagreeable effect of artificial light upon the eyes. By passing the light through alum or mica, the calorific rays are intercepted, and this unpleasant effect is obviated.

Arts.

NEW THINGS IN PHOTOGRAPHY.

THE *Photographic News* (London) gives a specimen of a new style of photographic picture to which the name *Albertype* has been given. The process is described as follows:—

"A plate of glass is covered with a solution of albumen, gelatine, and bichromate of potash, dried and exposed to light until hardened. It is then again covered with a solution of gelatine and bichromate of potash, and when dry exposed under the negative, and the film is then found to possess qualities analogous to a drawing made with fatty ink upon lithograph stone. All those portions of the film that were acted upon by the light will refuse water and take printing ink, while those portions which were protected from light by the negative will take water and refuse ink. The ink and water will be absorbed by the film just in accordance with the gradations of light and shade in the negative. To produce a picture, wet the surface of the film, then apply ink, lay on paper and pass through a press; the operation being substantially the same as lithography. The process is said to be rapid, and excellent pictures of all sizes may be printed in admirable style."

A photographer in Germany has invented a method of producing stamps and seals from photographs. A thin layer of gelatine made sensitive with bichromate of potash is exposed to light under a photographic positive, and the parts acted upon by the light become insoluble in water. The gelatine is then immersed in water, and the parts which have not been rendered insoluble, swell up, producing a picture in relief, from which a plaster cast is taken. From this an electrotype copy can be made which can be used as a seal. The process may also be employed for obtaining electrotypes for the use of the printer.

The *Athenæum* (London) states that copies of photographic pictures are now made in England by printing on ordinary paper with printer's ink, and that they can be done at the rate of 12,000 a day. The editor has seen some of these "mechanical photographs," as they are called, and pronounces them excellent.

The important problem of measuring distances and constructing plans and maps by means of photography has at length been solved by a Berlin photographer. He has surveyed a Prussian fortification for the government with complete success, and has constructed a photogrammetric instrument of such simplicity that a workman quite unacquainted with the art was able to draw up a special plan of a fortress on the scale of 1 to 2,500 after a few short instructions.

MINERAL DISCOVERIES.—M. Palm states in a recent number of *Cosmos* that he has been on a long journey through a portion of Turkestan which is little known to Europeans, and that, on his way, he studied the saline deposits of the country. Some of these deposits are very rich in sulphate of soda. Millions of tons of this important salt exist in this distant region, inhabited only by a few wandering tribes and by the Cossacks who do duty along the great roads as a military police.

On the eastern shores of the Caspian sea, abundant seams of coal have been found. The steam-ships navigating that sea have hitherto used wood for fuel, which had to be transported from the Ural mountains, at great cost. The coal is of very good quality. More than forty years ago, the late A. von Humboldt stated his belief that coal would be found in this region

at no great depth under the surface of the ground, since this entire locality abounds in naphtha.

On an estate belonging to M. Carnac, near Balhannah, South Australia, a very valuable lode of bismuth has been found, while some miners were seeking for copper ore. Since bismuth has very much increased in price, and is increasingly in demand, this discovery is a highly welcome one.

FUSIBLE ALLOYS. — An alloy of $7\frac{1}{2}$ parts of bismuth, 4 of lead, $1\frac{1}{2}$ of tin, and 2 of cadmium, melts at a temperature of 66° Centigrade, or 151° Fahrenheit. There are several alloys of bismuth, lead, and tin, which melt below the boiling point of water. The one which is simplest in composition, and most easily made, consists of 2 parts of bismuth, 1 of lead, and 1 of tin. A bit of it dropped into boiling water becomes at once a melted globule. The experiment is a good one for school use.

Bismuth melts at about 500° Fahrenheit, lead at 600° or more, and tin at 440°. The fact that the melting point of the alloy is lower than that of any one of the ingredients goes to show that alloys are, in some cases, to be regarded as chemical compounds, and not as mechanical mixtures. Other phenomena confirm this view; as the evolution of heat, when certain metals are melted together, and the fact that the density of an alloy is not what it should be if the metals were merely mixed.

STEAM BOILER INCRUSTATIONS. — We learn from *Cosmos* that a series of experiments, made on purpose, and continued for a sufficient length of time to yield a reliable result, has fully proved that the addition to the feed-water of the steam-boilers of fatty clays, especially the kind known as fuller's earth, entirely prevents boiler incrustations, even where, of necessity, very hard water has to be used as feed-water. A loose, soft mud is deposited as soon as the motion of the water, due to the boiling, ceases on cooling. This mud readily runs off on opening the sludge-valve of the boiler.

The *Annales de Génie Civil* informs us that these incrustations may be prevented by the use of raw potatoes, which cause all solid matters to be precipitated at the bottom of the boiler in a fine powder, leaving the sides perfectly free. The experiment was tried with an engine of 8-horse power, into the boiler of which ten kilogrammes of potatoes per week were introduced through the safety-valve. Every week, when the fires were extinguished, the deposit was removed previous to the introduction of a fresh supply of potatoes. On examining the boiler after fourteen consecutive months of work, no traces of incrustation were perceptible; the appearance of the plates was blackish and slightly greasy, and the corners of the joints were in the same state as when first made. Refuse leather-cuttings from the tanneries will answer the purpose equally well.

PROTECTION AGAINST FIRE. — Prof. Reinsch, having been requested by an insurance company to report upon the best means of protecting timber against fire, experimented with various salts, and at last came to the conclusion that common salt answers the purpose as well as anything that can be found. Timber impregnated with a concentrated solution of rock salt will not burst into a flame, any more than if coated with silicate of soda. The salt is of course much cheaper than the silicate, besides being also a preservative against dry rot and noxious insects. Reinsch suggests that salt water would be far more effective than fresh for use in fire-engines; but it would be likely to injure the machinery.

COLLODION FOR PROTECTING SILVER WARE. — The loss of silver from the action of sulphur compounds in the air, especially where gas is burned, is very great. It has been said that many thousands of dollars' worth of the precious metal go down our sewers annually in the form of dirt from the cleaning of plate. A silversmith named Strollberger, in Munich, has been trying various plans to save his silver, if possible. He covered his goods with a clear white varnish, but found that it soon turned yellow and spoiled the appearance of the ware. Then he tried a solution of silicate of potash, but this did not answer. After various experiments, it occurred to him to use a thin coating of collodion, which he finds to be just the thing. He first warms the articles to be coated, and then applies carefully a thinnish collodion, diluted with alcohol, using a wide soft brush for the purpose. Silver ware, protected in this way, has been exposed in his window for more than a year, and is as bright as ever, while articles left uncoated have become perfectly black in a few months.

ANTI-RUST VARNISH FOR IRON AND STEEL. — Such a varnish, according to the *Manufacturer and Builder*, may be made of

Resin	120 parts.
Sandarac	180 "
Gum lac	60 "
Essence of turpentine	120 "
Rectified alcohol	180 "

Pound the first three ingredients, digest them by a regular heat until they are melted, and add the turpentine very gradually. After complete solution has taken place, add the alcohol, and filter through fine cloth or thick filtering-paper. The varnish should be kept in well-stoppered bottles.

NEW METHOD OF CONCENTRATING SULPHURIC ACID. — The concentration of sulphuric acid in platinum vessels is very expensive, owing to the great cost of the apparatus and of any repairs which it may require from time to time. On the other hand, if glass retorts are used, there is a great loss of acid from the frequent breakage during the process of boiling down. The *Journal de Pharmacie et Chimie* describes a new method devised by M. Cotelle. He has had made a column, lined inside with fire-bricks, and made outside of good ordinary bricks; it rests on a large pedestal. This column is open at both top and bottom; but in these openings are fitted fire-clay stoppers. The inside of this apparatus is fitted with previously-calcined pumice-stone; inside the lower portion of this column, openings are made between the bricks, through which a current of highly heated air is forced. From the top, the acid which has to be concentrated is made to trickle on the pumice-stone, and, meeting with a current of highly-heated air, the superfluous water is driven off, and the acid, on arriving at the bottom, is in a concentrated state, and runs off in properly-arranged vessels.

ELECTRO-PLATING OF PAPER AND OTHER FIBROUS MATERIAL. — A method has been devised for depositing copper, silver, or gold, by the electric process, upon paper or any other fibrous material. This is effected by first rendering the paper a good conductor of electricity without coating it with any substance which will peel off. One of the best methods is to take a solution of nitrate of silver, pour in liquid ammonia till the precipitate formed at first is dissolved again; then to place the paper, silk, or muslin, for one or two hours, in this solution. After taking it out and drying it well, it is exposed to a current of hydrogen gas, which reduces the silver to a metallic state. The material thus becomes so good a conductor, that it can be electroplated in the usual manner.

A NEW WHITEWASH FOR WALLS. — Soak one-fourth of a pound of glue over night in tepid water. The next day put it into a tin vessel with a quart of water, set the vessel in a kettle of water over the fire, keep it there till it boils, and then stir until the glue is dissolved. Next put from six to eight pounds of Paris white into another vessel, add hot water and stir until it has the appearance of milk of lime. Add the sizing, stir well, and apply in the ordinary way while still warm.

"Paris white" is *sulphate of baryta*, and may be found at any drug or paint store.

VARNISH FOR IRON. — The following is M. Weiszkopf's method of coating iron with a durable black and lustrous varnish:

Take oil of turpentine, add to it, drop by drop, and while stirring, strong sulphuric acid, until a syrupy precipitate is quite formed, and no more of it is produced on further addition of a drop of acid. The liquid is now repeatedly washed with water, every time refreshed after a good stirring, until the water does not exhibit any more acid reaction on being tested with blue litmus paper. The precipitate is next brought upon a cloth filter, and after all the water has run off, the syrupy mass is fit for use. This thickish magma is painted over the iron with a brush; if it happens to be too stiff, it is previously diluted with some oil of turpentine. Immediately after the iron has been so painted, the paint is burnt in by a gentle heat, and, after cooling, the black surface is rubbed over with a piece of woollen stuff dipped in and moistened with linseed oil. According to the author, this varnish is not a simple covering of the surface, but it is chemically combined with the metal, and does not, therefore, wear off or peel off as other paints and varnishes do from iron.

A DEEP WELL. — We learn from the French periodical, *Les Mondes*, that the deepest Artesian well in the world is in this country, at Saint Louis. As long ago as 1854, this well had been bored to a depth of 2,199 feet, without reaching water-bearing strata. In 1865, the previously suspended borings were resumed, and are yet pushed forward; but though a depth of 2,852 feet has been reached, no water-bearing strata have been found. The borings now proceed only about three inches depth every day, in compact solid granite, and the cost per month amounts to $1,600.

TO CLEAN PAINT. — There is a very simple method to clean almost any kind of paint that has become dirty, and if our housewives should adopt it, it would save them a great deal of trouble. Provide a plate, with some of the best whiting to be had, and have ready some clean warm water, and a piece of flannel which dip into the water, and squeeze nearly dry; then take as much whiting as will adhere to it; apply it to the painted surface, when a little rubbing will instantly remove any dirt or grease. After which, wash the part well with clean water, rubbing it dry with a soft chamois. Paint thus cleaned looks as well as when first laid on, without any injury to the most delicate colors. It is far better than using soap, and does not require more than half the time and labor. — *Coachmakers' Journal.*

MELTING POINTS OF METALS. — The melting points of several metals have been very carefully determined in a recent series of experiments by A. von Riemsdyk, of the Royal Mint at Utrecht. The results are as follows: tin, 228.5° *centigrade;* bismuth, 268.3°; cadmium, 320°; lead, 326°; zinc, 420°; silver, 1040°; gold, 1240°; and copper, 1330°.

Agriculture.

THE MASSACHUSETTS AGRICULTURAL COLLEGE.

A CONSIDERABLE portion of the farm at Amherst is in a rough, unreclaimed condition, and not suited to the growth of crops. The grounds immediately around the college buildings have been underdrained, plowed, and brought into good tilth. There is evidently impatience on the part of some to have the whole farm put in fine condition so as to be pleasing to visitors, but we do not share in this feeling. It is not necessary or desirable to have a "fine show farm" maintained at the expense of the Commonwealth. In hastening to accomplish this end, the designs of the institution must necessarily be frustrated. When all the land is underdrained, what facilities for practical instruction of the pupils in this most important work will remain? When there are no more ditches to dig, or swamp lands to subdue, how can the young men be drilled in this department of labor? Manifestly it will be better to drain and work over small patches of land each year, so as to give each class an opportunity to observe, and participate in the work. If it requires fifty years to transform the magnificent farm into a garden, so much the better for the young farmers who are expected to graduate at the college. The buildings, for the most part, are elegant and convenient, and when those now in process of completion are finished, the wants of the institution will be quite satisfactorily met, so far as structures are concerned. The new "model barn" is, however, certainly open to criticism. If this embodies all the barn-building wisdom and genius of the State, there is less of it than we supposed. A barn furnishes a poor "model," if it is wanting in a special effective method for ventilating its cattle stalls. The root department of the State barn, we fear, is not out of the reach of frost, and there is no receptacle for saving the liquid excrement of the animals. However, the structure was reported as not completely finished, and perhaps it will be less objectionable when the last nail is driven.

The conservatory is very fine, and notwithstanding the fault that has been found with its establishment in connection with the college, it seems to us not a useless appendage. If young men can be taught to love and cultivate flowers, it will be a point gained. The country needs a corps of well instructed floriculturists and gardeners, and there is plenty of employment for such, with good wages.

Of the interior workings of the college we are hardly prepared to express opinions, as owing to want of time, no careful observations were made in that direction. Enough, however, was noticed to show that the arrangement of classes, and methods of instruction are excellent. The lecture system is adopted in the various branches of instruction; a system to be commended, provided the text-book and class recitations are not neglected. The professor of military tactics is also teacher of mathematics, and is regarded as a highly accomplished gentleman. In respect to discipline, we judge a plan bordering upon the "free and easy" is in vogue, and that the students, in the observance of rules, and in personal conduct, are thrown upon their honor and self-respect in a large measure. Perhaps this is best, as the institution is presumed to have connected with it a class of young men, differing in age and character from the usual run of college boys. If in authority at the college, we should venture to suggest that "pipes," if smoked at all, had better be smoked in the rooms or in some dark corner, rather than outside the building, on the piazzas, and about the grounds.

With a corps of enthusiastic competent instructors, and with every convenience and appliance for teaching the sciences, the college, as an *educational institution*, bids fair to prove a success. How decided will be its influence upon our agricultural interests remains to be seen. Undoubtedly a class of worthy young men will be graduated, and they will make themselves useful and influential members of society, as do the graduates of other colleges. But that many of them will become practical farmers, following the plow, and engaging in the active labors of the farm, is hardly probable. It remains to be proved whether any such institution as an "Agricultural College" is *possible*. It is easy to establish and endow an institution called by that name, but that does not prove that the idea, as popularly or generally understood, is a practicable one. It is extremely difficult to define what is meant by an agricultural college. However, it is certain that the experiment which the State is making at Amherst, is a magnificent one; and if the ends desired are not met, if it proves a failure in its direct and positive influence upon our husbandry, no other attempt must be made upon a similar basis. The experiment will be conclusive in its results, whatever they may be. With a considerable number of years' experience in conducting an experimental farm and endeavoring to bring the facts of science to the aid of agriculture, we are satisfied that a plan of instruction can be devised which would prove highly serviceable to the farming interests. The plan we would suggest is much less comprehensive and grand than is embraced in our State college. It is economical of time, inexpensive, and would have a direct bearing upon the soil cultivator himself, without regard to age or condition. At a future time we may venture to present the outlines of this plan.

A HEAVY CROP OF CORN. — Notwithstanding the unpromising appearance of our corn-fields at Lakeside in June, we have just harvested a crop, which must be regarded as extraordinary, even by those who most successfully cultivate the cereal. The field and crop have been carefully measured, and the result shows that *two hundred and nine bushels of ears* have been produced to the acre. This gives at least *one hundred and five bushels* of shelled corn to the acre. We have never heard of a larger yield in this section. If any of our farmer friends have done better, we shall be happy to record their success.

The corn in the bin is a splendid sight. The magnificent ears are of a brilliant yellow, and many of them 14 and 15 inches in length. In size and fulness of kernel, they could not be more satisfactory. Two and three ears grew upon a stalk, and so thick and luxuriant were the plants, it was difficult to penetrate into the field. Owing to this luxuriance, it was not touched with the hoe or cultivator *but once* from the time of planting. The field was a green sward turned over in the autumn of 1868, occupying a position midway between hills and lowland. In the spring, upon the furrows, were spread four cords of barnyard manure to the acre, and this was harrowed in and the soil finely pulverized with a Geddes harrow. The hills were three feet apart, and into them at planting was placed a handful of "bone and ashes" mixture; this was covered with a film of earth, and upon it five kernels of corn were dropped.

We attribute the success of the crop to *fall plowing, manure which held the liquid excrement of the animals, thorough spring pulverization of the soil, applying the manure to the surface, and to the use of the bone and ash mixture in the hills.* We believe the influence of this fertilizer was very essential in the production of the crop. The cost of the corn per bushel, including in the estimate one-half the cost of the fertilizers, is forty-five cents. This does not take into account the fodder, which, in our view, has a high value. The market price of corn of this quality is now one dollar and twenty-five cents per bushel.

MILK AND MILCH COWS.

THE following extract relating to milk and milch cows is taken from the address delivered before the Franklin County Agricultural Society by the editor of this JOURNAL. In response to the many requests made for copies of the address, we would say that it will appear in full in the Transactions of the Society, to be published in December. A few copies will be furnished us, printed separate from the volume; these we shall be happy to distribute among our friends who may apply for them. We shall make such extracts from the address, as we think will be of interest to our readers, and they will appear in future issues of the JOURNAL.

Among all the products of the farm there is nothing so interesting or wonderful as milk. Notwithstanding all that has been written regarding its chemical and physical properties, it is but imperfectly understood by those most directly interested in its production. That there is a want of knowledge of its properties even among intelligent men, is shown in the fact that a party of impudent adventurers can establish themselves in our cities, and by advertising, find plenty of customers ready to purchase a so-called invention, whereby a pound of good butter is alleged to be made from a pint of milk. If this were accomplished, it would of course be a miracle, equally wonderful with that of our Saviour who turned water into wine. It is certainly as much a supernatural act to change water into butter as to change that liquid into wine. Farmers, clergymen, lawyers have been made the victims of this audacious fraud. A pint of good milk weighs about sixteen ounces. If this were placed in a retort and gently distilled, we should obtain about fourteen and a half ounces of pure water; the solid matter remaining in the retort, weighing one and a half ounces, holds all the constituents in a pint of milk from which butter can be formed. Milk upon a fair average contains eighty-eight per cent of water; and consequently the farmer who carries to market one hundred gallons of honest milk has in his wagon eighty-eight gallons of honest water, which he honestly sells to his customers, at fair rates per gallon. It seems hardly necessary to carry the attenuation further, by resorting to the pump for more water. There is a popular impression that the water naturally existing in milk, vegetables, fruits, and grasses, in some way differs from that drawn from our wells and springs, but it is essentially the same. The water obtained from the sources named is pure water; that drawn from springs, etc., usually contains a few grains in the gallon of organic and inorganic matter, derived from the soil through which it percolates. This is all the difference. From whence comes the water found in milk? Manifestly it is derived from the grasses of the pasture, the hay from the mow, and the water drank by the animal. This all passes into the economy, and serves to dilute the various active principles upon which its value as food depends. Without calling your attention to those interesting points which relate to the chemistry of milk, I will remark upon the various forms of food best calculated to promote a copious secretion of the fluid in the animal.

During the past two years I have been led to make some careful and interesting experiments upon a herd of ten cows, which are kept upon my farm. The results of these experiments go to show what a vast difference exists in the value of the feed of pastures apparently similar in soil and situation, and also the difference in the green or succulent plants which are grown as food for cows, to be used in the late summer

and early autumn months. By changing my herd of animals, in the month of June, from one hill pasture to another, only a half mile apart, where the grasses were equally abundant, I found that the falling off of milk amounted in four days to fifteen quarts per day in the aggregrate. Upon changing them to the first field, the flow gradually increased until in about four days it was back again to its original quantity. The experiment of changing the animals was repeated three or four times with corresponding results. The explanation is afforded in the difference which existed in the grasses, in the amount of sweet nutriment which the water held in solution in the circulatory vessels of the plants. The quantity of food was abundant in both fields, and also the clover and the June grasses were produced in both; but in the one the juices were thin and watery, in the other they were richly laden with saccharine and nitrogenous products. The field giving the best results had been under the plow five years ago, the sod of the other had not been broken for a period of twenty years. We do not give sufficient attention to our pastures in Massachusetts, and by withholding fertilizing agents, and allowing the sod to become compact and cold, the growths are sadly deficient in milk-forming and flesh-forming constituents. I believe that it pays well to cultivate and give attention to pastures in all the thickly settled parts of the Commonwealth. One acre maintained in good tilth, so that nutritious and healthy grasses are produced, is worth to the farmer more than three which are suffering from neglect and exhaustion. This matter of securing or providing rich, healthy green food for milch cows, is certainly one of much importance, and should be fully understood by dairy farmers everywhere. We should learn that all edible plants which are green and juicy, and which animals consume with apparent relish, are not necessarily nutritious or profitable as food. We should learn that the richest variety of grasses and stalks of the cereal grains, are dwarfed and even become diseased under imperfect cultivation. The product of a field of clover or timothy grown in deficient sunlight, or under circumstances where there is an excess of soil moisture, or where the plants are crowded, has really a very low money value, compared with that of another produced under different conditions of light, moisture, and space. It is a common practice in Eastern Massachusetts, and perhaps in this section, to grow the corn plant in drills, or in a mass from broadcast sowing, to feed to milch cows late in summer when the pasture grasses fail. This is a kind of food for animals not profitable to raise. It is not so because the maize plant is not rich and succulent, but because the conditions under which it is grown are unfavorable to its perfect and healthy development. The natural juices of the plant are richly saccharine at maturity, when grown in hills in open space, with plenty of air and light; but grown in mass, in close contiguity, this principle is almost wholly wanting. To test its comparative value with the green stalks taken from the cornfield, I fed to my herd of cows in August a weighed quantity of the "corn fodder," so-called, night and morning for one week; they were then changed to the field cornstalks, and the gain in the milk product at the end of the week was a little more than eight per cent, and there was also a manifest improvement in quality. As a rule, all vegetable productions, grown under conditions where the chlorophyl, the green coloring principle of plants, cannot be produced in all its richness of tint, are abnormal, immature, worthless. The absence of this principle in the whole of the lower portion of the corn plant grown in drills, or from broadcast sowing, indicates its watery, half developed character.

As fodder for milch cows in summer, the sweet millet, green oats, and clover are much to be preferred to corn, and one or more of them should take its place upon all dairy farms. The water supplied to milch cows has an important bearing upon the lacteal secretion, and a few considerations demand our attention. With a knowledge of the large percentage normally present in milk, it is natural to conclude that a full supply should be always accessible both in pastures and in yards, and that the quality should be unexceptionable. Muddy, stagnant pools in pastures do not furnish the liquid in proper condition; and as milch cows are generally very fastidious regarding the sweetness and purity of water, they will remain for hours parched with thirst, before drinking at such sources of supply. This protracted thirst is fatal to the formation of milk, inasmuch as the animal is rendered nervous and fretful, and water is actually needed to enter into the secretion.

It is a curious fact that cows are often too lazy to go far from feeding grounds to drink, even when the water is pure and fresh. My pasture borders for a half mile upon the beautiful Kenosa Lake, a body of water of unsurpassed purity and excellence; and notwithstanding this, my herd will frequently come to the yard at night in mid-summer, actually suffering from thirst. To reach the lake it is necessary to go a few rods through a wooded portion of the pasture, and rather than travel that distance, they are willing to suffer the inconvenience of thirst. The annoyance is so serious, that I have determined to open a spring directly in the path leading to the yard.

The location of farmers' wells upon their premises is an important point. How often do you see them located within or upon the margin of the barn-yard, near huge manure heaps, reeking with ammoniacal and other gases, the prolific source of soluble salts which find access to the water, and render it unfit as a beverage for man or beast? It is well known that in the gradual decomposition of animal and vegetable substances at or near the surface of the earth, under certain conditions, nitrogenous compounds are formed. The nitre earths found under old buildings result from these changes. It is, however, quite difficult to understand the precise nature of the chemical transformations which produce them. In the waters of a large number of wells in towns and cities, and also in the country, the nitrates are found in considerable quantities. The salts form at the surface in warm weather, and being quite soluble, are carried with the percolating rain-water into the wells. Hence it will be understood how important it is to locate wells away from all contaminating influences.

It has long been a matter of surprise to me that instances of impure water are so often found in the rural districts, among those who are not confined to the narrow limits of city lots. In an experience of many years as consulting physician, I have had a larger percentage of examinations to make of water brought from country homes, than from any other source. The result of these examinations has proved that great carelessness is manifested in allowing sink drains, cesspools, and excrementitious deposits to exist in close proximity to the water supply, and serious illnesses have been caused thereby. I beg of you, gentlemen, to look carefully after your wells and springs, and permit no possible source of contamination to exist within a broad circle around the spot where they are located.

Management of Hyacinth and Tulip Bulbs. — The flower or flower-spike is wrapped up within the bulb, and only needs to be enticed from its prison-house in such a manner that it shall not appear in dishabille. Now, to do this cleverly, the free formation of roots must be induced before the growth of the leaves or flower-stem is excited.

The following rules will be useful to parlor florists:

In choosing bulbs, look for weight as well as size, and be sure that the base of the bulb is sound. Use single kinds only; they are earlier and hardier. Set the bulb in the glass so that the lower end is almost, but not quite, in contact with the water. Use rain or pond water. Do not change the water, but keep a small lump of charcoal at the bottom of the glass. Fill the glass up from time to time. When the bulb is placed, put the glass in a cool dark cupboard or other place where light is excluded. When the roots are fully developed, and the flower-spike is pushing into life (which will be in about six weeks,) remove by degrees to full light and air. The more light given from the time the flowers show color, the shorter will be the leaves and spike, and the brighter the color.

Boston Journal of Chemistry.

BOSTON, DECEMBER 1, 1869.

SPONTANEOUS COMBUSTION OF THE HUMAN BODY.

In a former number of the Journal we spoke of the belief in the spontaneous combustion of the human body as "a vulgar superstition." A correspondent calls our attention to articles in cyclopædias, which refer to "well authenticated instances" of such combustion. Let us examine this matter in the light of what is actually known.

We must, in the first place, carefully distinguish between the notion of "a *preternatural combustibility*" of the body under certain abnormal conditions, and that of its *spontaneous combustion*. The former is not impossible; indeed, there are tolerably "well authenticated instances" of the kind. The latter, if not absolutely inconceivable, is in the highest degree improbable, and eminent physiologists who have carefully investigated all the cases in which it is alleged to have occurred, do not find a single one established beyond a doubt.

The earliest case of the kind which has a semblance of authority to sustain it, is said to have happened in 1725, and from that time down to the year 1847, when the last alleged case occurred, some fifty instances are recorded. Liebig made an analysis of all these cases in 1851, and found that they nearly all agree in the following points:

1. They took place in winter. 2. The victims were hard drinkers, and were drunk at the time. 3. They happened where the rooms were heated with fires in open fire-places or pans of glowing charcoal. Cases where rooms are heated by means of closed stoves are exceedingly rare. 4. It is admitted that no one has ever been present during the combustion. 5. No one of the physicians who collected the cases, or attempted to explain them, has ever observed the process, or ascertained what preceded the combustion. 6. No one has known how much time had elapsed from the beginning of the combustion to the moment when the consumed body was found.

Out of forty-five cases collected by Frank, of Berlin, in 1843, there are only three in which it is assumed that the combustion occurred when there was no fire in the neighborhood; and Liebig clearly shows that these three

cases are totally unworthy of belief. The conclusion to which he comes is that "spontaneous combustion in a living body is *absolutely impossible.*" Flesh which has been saturated with alcohol for a great length of time, as anatomical preparations, is not combustible; if ignited, the alcohol burns off, scarcely charring the flesh. The corpses of drunkards have never been found to be combustible.

M. Duvergie has opposed Liebig's views, and has expressed the opinion that molecular changes may take place in the living body by which it becomes more combustible from the absorption of alcohol, or from its conversion into more inflammable compounds; but he admits that the combustion is probably never spontaneous. Dr. Marc has suggested that inflammable gases, and possibly even phosphoretted hydrogen, which, under certain circumstances, inflames on contact with the air, may be generated in the living body, and may thus give rise to its spontaneous combustion; but this is merely a theory to account for such cases of combustion, *if* they *have* occurred.

On the whole, this idea of spontaneous combustion appears to be one of those old medical delusions which, having once gained a sort of credence, are not readily given up. It is easy to see, as Liebig observes, that it arose at a time when men entertained entirely false views on the subject of combustion, its essence, and its cause. It is only since the time of Davy, or for about half a century, that combustion has come to be thoroughly understood. After people had once got it into their heads that the body might take fire of itself, it is not singular that when a man happened to be burned up, the case was explained in that way if it could not readily be accounted for in any other way; just as hundreds of fires caused by carelessness, not easily detected, are charged to the mysterious "incendiary." Then again, other things being equal, the more marvellous explanation of strange phenomena is usually the more popular one. The Latin proverb *omni ignotum pro magnifico est* might be read *omni ignotum pro mirifico est*, with everybody whatever is unknown passes for a marvel. We need not be surprised, therefore, that this idea of human combustibility, which was not inconsistent with the scientific knowledge of the age in which it had its origin and which consequently came to be accepted by the scientific men of the time, should still live as a popular superstition and even find an occasional defender among the *savants* of this more enlightened day.

MARY SOMERVILLE.

A notice of this eminent woman in the *Scientific American* states that she was born in Scotland about the year 1796, and that her first husband was Samuel Gray, Esq. According to *Chambers' Cyclopædia*, which is excellent authority, she was born "about the year 1780," and married Capt. Samuel *Greig* in 1804. Capt. Greig died in 1806, and in 1812 his widow married Dr. William Somerville, of Edinboro', who died in 1860, at the advanced age of 91. The *Edinburgh Review* for July, speaks of Mrs. Somerville as being *in her eightieth year* when her work on "Molecular and Microscopic Science," was published, in 1868. It will be seen that this is inconsistent with both the dates of her birth just mentioned.

The following extract from the article in the *Edinburgh* will interest our readers:

"The world is not unfrequently called upon to admire the keen interest and powerful grasp which veterans foremost in the ranks of science retain in their various pursuits up to the latest moments of an advanced age. It is, however, we believe, a case without a parallel in the annals of science, that a lady in her eightieth year should publish a work containing a complete review of some of the most recent and abstruse researches of modern science, describing not only the discoveries in physics and chemistry, but especially the revelations of the microscope in the vegetable and animal worlds. Before many distinguished cultivators of the sciences she loves so well were born, Mrs. Somerville had taken a place among original investigators of nature, as in 1826 she presented to the Royal Society a paper on the magnetizing power of the more refrangible solar rays. This communication is printed in the 'Philosophical Transactions,' and led to much discussion on a difficult point of experimental inquiry, which was only set at rest some years later by the researches of Riess and Moser, two distinguished German electricians, in which the action upon the magnetic needle was shown not to have been caused by the violet rays. In 1832 she published her 'Mechanism of the Heavens,' and in 1834 she became still more widely known by the appearance of her 'Connection of the Physical Sciences,' and the 'Physical Geography.' These works have passed through many editions, and have been translated into several foreign languages; whilst in this country her services to geographical science have been recognized by the award of the Victoria medal for 1869 of the Royal Geographical Society. In her work on 'Molecular and Microscopic Science,' the gift of lucid description, so characteristic of the distinguished authoress of the 'Connection of the Physical Sciences,' is as conspicuous as ever; but that which most forcibly strikes the reader of these pages is the extraordinary power of mental assimilation of scientific facts and theories which Mrs. Somerville displays."

FOREIGN NOTES.

At the annual meeting of the French Institute this year, M. Charles Blanc read an "Essay on the Æsthetics of Lines," in which he protested against English landscape gardening, which has so properly dethroned the French gardening all over the world. He said: "When one wishes to make the plan of an English garden, one has but to make his gardener drunk and to follow his reelings."

The French government sends annually a man-of-war with the graduating pupils of the Naval School on a long voyage, to perfect them in the practical part of their studies. It has been decided to send hereafter on board this ship several scientific men, amply equipped with the necessary books and instruments. The Academy of Sciences will give them instructions upon the researches to be made. A committee, including Faye, Becquerel, Boussingault, and Milne-Edwards, has been appointed to prepare these instructions. The leading subjects of investigation will be the marine fauna at great depths; the conditions in which endemic diseases are developed; the temperature of the sea at its surface and at different depths, in mid-ocean, near land, at the centre and edges of currents; the nature of the zodiacal light, etc.

Prof. Boehm, one of the most eminent medical men of Berlin, died a few days since under fearful circumstances. While dissecting before a class of students, he pricked a finger. He thought it a mere abrasion of the skin, and failed to cauterize it. Two days afterwards his hand began to swell, and became enormous. The poison pervaded his whole system and killed him. He retained his consciousness nearly to the last, and saw his end approach with undisturbed firmness.

It is said that the Swedish government requires that every passenger train on railways shall be furnished with a competent medical officer, with all the medical and surgical appliances necessary. It would be well if some of our railways were similarly equipped.

Twenty-five years ago, Claude Bernard, the eminent physiologist, who has lately been made a Senator and Academician, was an apothecary's assistant in a country town in France.

A New Asteroid.—On the 9th of October a new minor planet was discovered by Dr. C. H. F. Peters, at the observatory of Hamilton College, N. Y. It is the 109th member of the group, and has just passed its opposition. It shines as a star of the tenth magnitude. This is the ninth planetoid discovered by Dr. Peters. Nine have been detected by another American astronomer—Prof. Watson, of Ann Arbor, Michigan. Among European observers, Hind has discovered ten, and Luther no less than seventeen. It is but fair to state, however, that Luther has been engaged in the search for the last twenty years, while Peters began his discoveries in 1861, and Watson in 1863. Last year, Watson was lucky enough to pick up *three planets within ten days*, namely, on September 7th, 13th and 16th. In 1867 he found one on the 24th of August, and another on the 6th of September. In one instance, Goldschmidt, a European observer, caught a couple of them on the same day, September 19, 1857.

Morphine.—*The Boston Medical and Surgical Journal* of November 11, copies from a New York Druggist's Price Current, a most slanderous article in which "parties in Boston" are charged with the *crime* of smuggling *morphine* into this city and selling it to the trade.

We do not believe there is, or ever has been a single ounce of "Scotch smuggled morphine" in this city, and we have no hesitation in pronouncing the statements false and malicious.

To "smuggle morphine" or any other dutiable commodity into the United States, is a *high crime*, and every good citizen is, or should be, interested in bringing parties thus offending to punishment. The very respectable *Boston Medical and Surgical Journal*, by copying the statements of an *irresponsible* New York Price Current, has indorsed them, and has thus become a party to the assault on "some parties in Boston." Therefore, there is a *responsible* party introduced into the arena. We fear that the editor and publisher of the *Boston Medical and Surgical Journal* may suffer from publishing statements of a libellous character

The yellow slip upon the margin of each Journal gives the date to which payments have been made. Those who are not credited as having paid to July, 1870, will please inclose to us the amount due without delay.

Buds and Blossoms out of Season.—A correspondent calls attention to the fact, that many of the fruit and ornamental trees along the New England coast are in blossom this autumn, and suggests that this may be due to the great gale of September 8th. It is well-known that, during the last of August and the first of September, trees and shrubs are making their second growth, and there is a large flow of sap to support this growth, and that the elaboration of this sap takes place in the leaves. The gale removed the leaves, and this vigorous flow of sap, turned from its natural course,

forced the dormant buds to burst and put forth leaves and flowers. The fruit buds of deciduous trees, as well as the leaf buds, are *formed* in August and *matured* in September; and although their covering is sufficient to withstand the winter's cold and storms, the powerful wrenching they received before they were ripe may have broken the envelope, so that these buds also were forced into premature development by the active circulation. If this explanation is correct, it is not unreasonable to suppose, as our correspondent does, that the fruit crop of 1870 will be lessened.

MAKING A NEW SEA. — The *Italie*, of Florence, says that M. de Lesseps, after having connected two seas, is now proposing to create a new one. It has been suggested that the Sahara is the bed of an old sea displaced by some natural convulsion. This has led M. de Lesseps to send engineers to examine the region, and their report has satisfied him that the Sahara at the point nearest to the Red Sea is twenty-seven metres below the level of that sea, and that the depression increases towards the interior. He believes, therefore, that a canal seventy-five miles long would suffice to flood the Sahara from the Red Sea, and thus restore the desert to its primeval destination.

It would be rash to assert that this project is impracticable; but it is not likely to be entered upon without a careful consideration of the influence it might have upon the climate of neighboring regions, and especially upon that of the Mediterranean and Southern Europe. We will not venture to say precisely how the substitution of a great sea for a great desert would affect the meteorology of large portions of both Africa and Europe, but we doubt whether the parties interested will decide to risk the tremendous experiment.

WHAT BECOMES OF OLD SHOES? — *Cosmos* answers this question by stating that they are cut up in small pieces, and these are put for a couple of days in chloride of sulphur, which makes the leather very hard and brittle. After this is effected, the material is washed with water, dried, ground to powder, and mixed with some substance which makes the particles adhere together, as shellac, good glue, or thick solution of gum. It is then pressed into moulds, and shaped into combs, buttons, knife-handles, and many other articles.

OXYGEN FOR ILLUMINATION. — We have explained to the readers of the JOURNAL the new and cheap method invented in France for preparing oxygen on a large scale by the *de*oxidizing and *re*oxidizing of the manganate of soda. The New York Oxygen Gas Company has been incorporated for the manufacture of oxygen by this process, with a view to its use for purposes of illumination. Their works cover eight lots of ground, and consist of extensive buildings of brick and corrugated iron, powerful blowing and compressing engines, an ample gas-holder, and a large French furnace, with twelve retorts, each large enough to contain eight hundred pounds of the manganate. These retorts are now producing oxygen at the rate of 25,000 cubic feet per day.

In Paris, oxygen has already been used as an aid to lighting, in the Court of the Tuileries, the Hotel de Ville, and in the Gaiété and Alcazar Theatres. The whiteness and brilliancy of the light are far superior to that of ordinary gas-burners, and it is no slight additional merit of the system that it does not rob the air of its oxygen.

MERCATOR THE MAP-MAKER. — In most atlases is a map of "The World after Mercator's projection." Very few know who Gerard Mercator was. This geographer was born at Ruremonde, in Holland, in 1512, and died at Doesburg in 1594. He obtained the favor of the Emperor Charles V. by presenting him with some well-executed terrestrial globes. In 1559, he settled at Doesburg, as cosmographist to the Grand Duke of Cleves. He was the best map-maker of his time, and is said to have invented the plan of laying down maps and charts by a projection of the earth *in plano*. It is incorrectly believed by many persons that Mercator did not acknowledge that the earth was globular. After having been neglected for a long time, honor to Mercator has just been rendered by laying, with great solemnity, the first stone of a monument to him at Doesburg.

QUESTIONS AND ANSWERS. — A year or two ago when the circulation of the JOURNAL was comparatively small, we gave each month a series of answers to questions propounded. As the circulation increased, the questions poured in upon us so freely, it was found impossible to reply to a fiftieth part of those asked, and therefore, not to be partial, we discontinued answering any of those received. This feature of the paper was popular, and many requests have been made to have it resumed. It is probable that it will be in the next volume, if not before. We can, however, pay no attention to questions asked to promote private interests, or if the answers will not prove useful and instructive to our readers.

ERRATA. — On page 52, for "*Preservation* of Copal Varnish," read "Preparation." On the same page, in the article on "Great Laboratories," the P from "Prussian" got shifted to the other end of the line, where it appears in Dr. A. W. Hofmann's name. The printer then changed "russian" to "Russian," improving the orthography at the expense of the geography. All this happened after the proofs had passed out of our hands.

LITERARY NOTES.

MESSRS. Macmillan & Co., of London, have established a branch house in New York, at 63 Bleecker street, where they furnish their large list of scientific and other works at prices considerably below those which an importer of English books would have to charge. Among their latest issues is a revised and enlarged edition of Roscoe's "Chemistry." In its present form it is much to be preferred to the American reprint of the earlier edition, while its cost is no higher. The most important additions are in the chapter on spectrum analysis, a subject on which Prof. Roscoe has published an elaborate work, already noticed in our columns.

Another book of great interest to the chemist is Wurtz's "History of Chemical Theory," translated by Watts. It gives a concise sketch of the development of chemical philosophy from the day of Lavoisier down to our own. We shall refer to it again, and may have occasion to draw some material from its pages.

Macmillan & Co. have published several elementary books of natural science which belong to the same series with Roscoe's "Chemistry"; as Huxley's "Elementary Physiology," which has also been revised and enlarged in the third edition, Lockyer's "Elementary Astronomy," and Oliver's "Elementary Botany."

We are ashamed to say that, with very rare exceptions, (some of which have been made the subject of notices in the JOURNAL) our American text-books on science, for school use, are greatly inferior to these English manuals. In England, the natural sciences are either not taught at all — and this is too frequently the case, even in schools of the same grade as our high-schools — or they are taught better than is done in this country.

Of the books just mentioned, the most elementary one is the "Botany," which is partly based upon material, left in manuscript by the late Professor Henslow, whose method of teaching botany in village schools attracted great attention in England several years ago. It is essentially an "object lesson" method, with some novel features, which cannot well be described in a brief notice like this.

What we have said of foreign text-books as compared with our own is equally true of popular books on science. We have very few really good things of the kind published here, which are not reprints or translations. Two or three of our publishers are now reproducing volumes from the "Library of Wonders," which has been so popular in France and England. Messrs. Scribner & Co. have issued five of these books: "The Wonders of Optics," "The Wonders of Heat," "Thunder and Lightning," "Intelligence of Animals," and "Great Hunts." The first two of the series are model books of their class, giving all the recent discoveries in Light and Heat in a clear and attractive style. They are hardly books for children, unless it be as collateral reading for children studying these subjects at school. The other three may be ranked as "juveniles," though many children of larger growth will read them with interest. We should be glad to see such books taking the place of the sensational stories — juvenile *novels*, for they are nothing else — with which the press is flooding the country.

The Appletons have also begun a "Library of Wonders." The first volumes are "Meteors and Atmospheric Phenomena," a well-written and well-illustrated manual of meteorology for popular reading; and "Arms and Armour," which describes, with the aid of many excellent cuts, all the arms and weapons of all the ages from the antediluvian down to the present. Both these books are from the French, the latter with additions made by the English editor.

A copy of the *seventh edition* of the "Elements of Chemistry," by W. J. Rolfe and J. A. Gillet, of Cambridge, Mass., has been sent us by the publishers, Woolworth, Ainsworth & Co., of Boston. The speedy call for a seventh edition of this most valuable and accurate elementary treatise upon chemistry, affords gratifying evidence of the just appreciation of the work by school committees, teachers, and others. In this edition the authors have gone over the entire book, and have made important additions, together with such changes as progress in the science demanded. It is a work worthy the confidence of all interested in the education of the youth of our country.

We find on our table "Medical Education: an Oration delivered before the New Hampshire Medical Society, at the annual Meeting at Concord, June 15, 1869, by W. D. Buck, A. M., M. D." It is lively and readable, giving a good deal of "sound doctrine" in a pleasant, free-and-easy way.

"The Reconstructed Farmer" is a monthly magazine, devoted to the farm, the garden, and the household, which comes to us from Tarboro, North Carolina. We hope it is properly appreciated by the farmers of that region, for it well deserves their patronage.

☞ We cannot undertake to preserve or return communications not published in the JOURNAL.

Medicine and Pharmacy.

M. VELPEAU.

We find in the August number of the *Nineteenth Century*, an able literary magazine, published at Charleston, S. C., a most interesting sketch of the great French surgeon, *M. Velpeau.* A very large number of our medical readers, who have often followed the distinguished savant through the wards of *La Charité*, and listened to his brilliant lectures, will attest the faithfulness of the portrait drawn by the writer. Probably no man ever lived who *caused* or *relieved* more human misery than Velpeau. His operations were always performed with great celerity, and apparently with entire forgetfulness of the fact that his knife or probe was incising or perforating living tissues. He was a kind man, and yet seemingly insensible to suffering. No one who has ever seen Velpeau will forget the spare, modest, *busy* man, whose fame as a surgeon can never die. When ether was brought to his notice as an anæsthetic twenty years ago, he condemned its use, and would have nothing to do with it, until others had proved its usefulness and safety. His comparatively recent death has left a void in the ranks of surgeons not easily filled. The writer of the sketch which we present below, after describing the scenes in the hospital, continues as follows:

Far from where you enter, stand a throng of men, some crowding around a particular bed, some with hats on, others uncovered. From out their number moves an individual whom you did not, at first, observe, but whom every one seems to follow, as he passes rapidly from one bed to another, squeezing his way in among those encircling him. He is a person with a sharp, greyish eye, of middle height, more tall than short, inclined to be thin, and moves unobservingly by, unless when he stops, occasionally, as the inclination seizes him, to ask some question of a favorite chef-de-clinique, or of a sister. He will sometimes not speak or smile for a half hour, unless on the subject of medicine, or the case before him; at other times he smiles and even makes a little dry fun with the sick man, though he never laughs; often, if induced to relax at something particularly ludicrous, he soon recovers himself, becomes grave, or rather I should say earnest, and his eye looks as piercing as before. Neither his voice nor manner is soft or winning, although they show, when he speaks to a boy, or when the gravity of the case is imminent, that his heart is full of feeling, and that even habit, time, and the knife have not made him entirely callous to the sufferings of the unfortunate. I have heard him quiz a little *Interne* with white hair, upon the color of his moustache; but it was not done in a genial way; it was as a surgeon would quiz, and you only laughed because the great man laughed. He also wears a white apron with pockets, from which dangles a pin-cushion, and on his head is a purple velvet skull-cap, with tassel. Thin grey hair escapes from beneath, and you are quite surprised when, upon inquiry, you are told that is the great surgical Amphitryon of La Charité and of France, M. Velpeau.

Here is a true veteran for you; here is a surgeon with the three requisites — a lady's hand, an eagle's eye and a lion's heart; here is the man who enjoys the "*digitis monstror prætereuntium*"; you see, at last, one that you have been hearing of all your life, and before you ever thought of medicine; you have, perhaps, heard your cousin or your friend, who was in Paris years before you, speak of seeing Velpeau cut off an arm, or a hand, on such and such a morning, and you yourself also watch him do the same thing, on the same spot, fifty times; in fact, you may see him perform two or three operations almost every morning if you will take the trouble to be at his amphitheatre at La Charité. He will cut for stone, operate two or three times for cross-eye, take out tumors from the breasts of two or three women, amputate a finger, a thumb, or a leg, almost any morning you choose to name, after he has visited these long lines of beds up stairs and down stairs, in male and female wards, and after he has lectured an hour, and all before breakfast. Heaven knows at what hour he has risen, or what he has not written in one of the works he is publishing, the "*Nouveaux Eléments de Médécine Opératoire*," or some other. But I do know that he has not yet finished, because, before his carriage and pair leave the Rue Jacob, in front of La Charité, and when you have gone to the Café de Paris, to Madam Dijon's, to 66 Rue de Seine, or with me to my rooms on the garden of the Luxembourg, *he* has remained to prescribe for a score of what are called out-door patients, whom he examines as fast as they can be marshalled in the room on the ground floor. Then M. Velpeau's private consultations at his own residence, and his visits, have not yet commenced. But notwithstanding, you will sometimes meet him on the *Pont Neuf*, or the *Pont du Carrousel*, with a young lady on his arm, as like as father and daughter can be, while they walk to the Louvre or the garden of the Tuileries. And you ask again, is this man, strolling quietly by, the hero of a hundred bloody operations, the creator of bold systems, and originator of new modes of practice — the bold generalizer, who has laid a master hand on almost every department of medicine; who has written a hundred volumes; whom everybody quotes, even men who study specialties, and who recognize that, during a life of ceaseless toil and exertion, *he* has made a specialty of every department of his profession, and has rendered himself as competent to pronounce upon their respective merits as any enthusiast of a single one — whether it be in surgery, materia medica, obstetrics, physiology, diseases of the eye, or anything you please to name? M. Velpeau is a bold, successful innovator in each and every one, and he has stamped his name in every text-book that the student uses. He has written, and now writes, tomes filled with costly illustrations, which the medical world reads and consults, and swears at sometimes, but always quotes or follows. There are none so dauntless as not to do him reverence; none so bold but do not ask what Velpeau said this morning at a clinique. Does he discover anything, he seeks to have Velpeau test it. With Velpeau's sanction, he is confident against the world in arms, and goes forth with redoubled zeal. Does Velpeau damn the new project, it is like a dash of cold water, and the thermometer of his ardor falls instantly. I think that, generally, M. Velpeau, after his very large and most enlightened experience and observation, has a right to pronounce, and that he does so cautiously and with discrimination. He has, at times, been quick, and, perhaps, wrong, and I think now the microscopists will make him rue the day that he decided too dogmatically against their true and false cancers; for, already MM. Lebert and Robin will show him that the glass is surer and more unerring than the unaided experience of even *his* eye and finger, and he will confess, or what is worse, posterity will do it for him, that true cancer and the unmalignant fibro-plastic growths reveal themselves by signs, more certain than those gained by observation and sight simply. Perhaps, too, M. Ricord, or his successors, will demonstrate, that in proclaiming his doctrine of syphilization, a true advance has been made which time will sanction and enforce, and that its cardinal points are *real*, which M. Velpeau utterly repudiates and rejects *ab ovo*, root and branch. Velpeau must recollect that Ricord, though young and vigorous, resembles him in one respect — *he* does not take vacation either.* An old man, however great, is apt to remember triumphs won in youth from giants, and he grows too confident thereby. He is apt to forget that the tables turn, as age advances and years roll by, and when the conflict lies between the old and the youthful, but, at the same time, the vigorous, the cautious, and the observant.

[TO BE CONTINUED.]

* M. Ricord informed me that, with the exception of the last, he had not indulged in the ordinary *vacance* of the Paris doctor for twenty years. He was at the *Hopital du Midi* the year round.

FOR RINGWORM.

℞. Washed Sulphur, 22 grains.
Carbonate of Potash, 8 grains.
Lard, 1 ounce.

Mix. Continue the application some time after the apparent cure, in order to prevent a return. — *L'Union Medicale.*

MEDICAL MEMORANDA.

The Insurance Times urges that companies should guarantee medical attendance to all whose lives they insure. It would accomplish this by having one or more physicians, with fixed salary, attached to each company and charged with the duty of attending the sick among the policy-holders. The plan might be feasible in communities where the number of the insured is large, but it strikes us that it would be inconvenient and costly to extend it to the more scattered patrons of the company. There are other practical difficulties which will readily suggest themselves to one who gives the subject a little consideration, but we will not say that they are insurmountable. The plan is at least worthy of attention and discussion.

A solution of common salt has been recommended as an antidote in cases of strychnia poisoning. It is said that it has been tried repeatedly with dogs, and that it has invariably proved successful.

Sulphuretted hydrogen is found to be a direct antidote to the poisonous effects produced by inhaling chlorine.

It is said that delirium tremens is unknown among negroes. Dr. Autry, in a communication to the Medical and Surgical Reporter, adds the fact that he has never seen a case of the disease in the Indian race, in twelve years' practice of medicine in Mexico, where three-fourths of the inhabitants are Indians, and addicted to excessive use of the very worst kinds of liquor.

In a later number of the Reporter, Dr. Chittenden, of Binghamton, N. Y., states that he has had one negro under treatment for delirium tremens, and that the diagnosis was unmistakable.

A Noble List of Names. — Our printer, after three months' labor, has just completed the task of putting the names of all our subscribers in type, the printed names to be used in the mailing department of the Journal. Some idea of the magnitude of the work may be obtained from the statement, that it has taken *over one ton of type*, or as much as one horse could draw in a cart through the streets of the city.

The names printed as close together as possible, upon a ribbon of paper, would require a length nearly twice the height of Bunker Hill Monument.

Upon looking over this list of names, we find those of men and women distinguished in every department of art, science, and literature — Professors in Colleges, Schools, etc., Teachers, Physicians, Druggists, Chemists, Artisans, Farmers, etc. These are scattered all over the country, in every State and Territory of the Union. Of physicians we have nearly *ten thousand* subscribers. We have reason to be proud of the patrons of our little Journal. There is among these a very large number of enthusiastic friends, who send us often the kindest words of encouragement. Success to them in all their undertakings.

Test for Adulterations of Chloroform. — Chloroform is not unfrequently adulterated with alcohol and ether. To test it for these substances, treat it first with fused chloride of calcium to eliminate any water which it may contain, and then add iodine. If no alcohol or ether is present, the color produced is *bright red;* if either alcohol or ether is present, it will be *brown.* To distinguish alcohol and ether, add a small piece of crystal of fuchsine. The slightest trace of alcohol gives a deep red. Pure chloroform yields with fuchsine a solution of slightly pinkish tinge.

TREATMENT OF DANDRUFF. — HARDY. — Nitric acid 12 minims; Distilled water 3 ounces. Mix and apply once a day. — *L'Union Medicale.*

RAT POISON. — Recent experiments have shown that squills is an excellent poison for rats. The powder should be mixed with some fatty substance, and spread upon slices of bread. The pulp of onions is also good. Rats are very fond of either. — *Journal de Chimie.*

HAIR-OIL FOR HORSES. — The following recipe for making hair-oil for horses is "going the rounds." Of its efficacy we entertain the highest opinion, and, as it is perfectly safe, take pleasure in recommending it.

R. (take.) Brushus et curricombus — ad libitum; elbow grasus — quantum sufficius; blanketisus — first ratus; stablus (in winter) — warmus; fodderus — never say dietus, but mealus et oatus; exercisus — non compromisus. The effect will be: coatus shinus; appetitus wolfitus; muscularitus, two-forty-itus. — *Horse's Friend.*

Messrs. Besson and Kneider, professors in the Lyceums at Strasburg and Mulhausen, have invented an "electric warmer" to aid in regulating the temperature of hot-houses and other buildings in which it is desirable to maintain a nearly uniform heat. Whenever the temperature rises to a certain maximum or falls to a certain minimum, a set of electric bells ring and attract the attention of the guardians or workmen.

Sir Robert Peel once presented a farmers' club in England with two iron plows of the best build. On his next visit, he found the old plows with wooden mould-boards again at work. "Sir," said a member of the club, "we tried the iron, and we be all of one mind that they do make the weeds grow."

A Chicago physician, much devoted to real estate speculations, and rather absent-minded, replied to the question of a lady how his prescription was to be taken: "One-quarter down; balance in one, two and three years."

JET BLACK VARNISH FOR SHOES. — Dissolve 10 parts by weight of shellac and 5 of turpentine in 40 of strong alcohol, in which fluid should be previously dissolved 1 part of extract of logwood, with some neutral chromate of potassa and sulphate of indigo. The varnish is to be kept in well-stoppered bottles.

VARNISH IN BURNS. — Paris is much interested in a remedy discovered by a workman, who, to relieve the pain from a severe burn, thrust his hand into a pot of varnish which happened to be at his side. The relief was so sudden, and the healing of the wound so rapid, that the news spread, with the result of bringing to him every one in the neighborhood who had a burn. Many wonderful cures are said to have been performed at the time of the great explosion in Metz, last September, and the discoverer has been summoned to Paris, to make some public experiments. — *Journal de Chimie.*

TO ARREST THE DECAY OF TEETH. — Mix nitric ether and the phosphate of aluminum in proportions such as to make a paste. Fill the cavity of the decayed tooth with this, which is perfectly harmless, and the toothache, however violent, is generally relieved at once. By repeating it each time that the pain returns, the tooth is rendered insensible. — *Journal de Chimie.*

A MODEL DOCUMENT. — The following is a literal transcript of a document written by a practising physician in this city and offered as evidence in a case in the Police Court recently. If the writer's knowledge of medicine is as extended as his orthographical acquirements, the profession would do well to hunt him out.

"I was called on to go and see Samel snapinsca on the 11 september i found him in bead and was brused vary bad his ribs on the left side varey badly brused and the left lung apeers to be ingered from the bruses and there was severil bruses on his body besides." — *Detroit Free Press.*

CINCHO QUININE.

Hundreds of letters have been received from physicians in every State and territory of the United States, in which most favorable statements are made regarding the cincho quinine. Extracts from a few are here presented.

From William Cooper, M. D., New Albany, Indiana.

I am happy to state that the results of the use of cincho quinine have been eminently satisfactory; not a single instance of its failure to produce the expected effects has come to my knowledge.

Many of my patients, after using it, have specially requested that the cincho quinine be given them instead of the sulphate. No complaint has been made of nervous disturbance. I have used it in all cases where the sulphate of quinine was indicated, and with equally good results. I think when physicians have given it a fair and impartial trial, they will use it in preference to all other preparations of the barks, in our autumnal fevers.

From James Lamb, M. D., Aurora, Indiana.

I have been using the cincho quinine considerably of late, and I prefer it to the sulphate of quinine, in most cases. I think it affects the head less; but it requires a somewhat larger dose. I think it a better tonic than the sulphate, but do not regard its anti-periodical powers as equal to it. It is a very valuable addition to our list of tonics; and as it is cheaper and more readily taken than quinine, I shall continue to use it, and recommend it to my medical brethren.

From H. H. Beebe, M. D., Marshall, Wisconsin.

I have not fully tested the anti-periodic powers of the cincho quinine, but have prescribed it as a tonic with uniformly good effects. The stomach seems to tolerate it well, and it is pleasant to take; and as far as I have observed, it produces no cerebral distress.

From Ira R. Wells, M. D., Genesee, Illinois.

I have used nine ounces of cincho quinine; and in cases of intermittent fever, I find it fully as efficacious as sulphate of quinine. A favorite prescription of mine is as follows:

Cincho Quinine, xii. gra.
Leptandrin, xxv. "

Mix and divide into vi. doses, one of these to be taken every three hours. This in all cases has promptly arrested intermittents, and my patients do not complain of the unpleasant head effects which follow from the use of the sulphate of quinine. The cincho quinine will frequently be borne by the stomach when the sulphate will not, and I regard it as a better tonic. In some cases of congestive fever, I prefer the action of the sulphate to the cincho quinine.

From E. W. Knepper, M. D., Ligouier, Indiana.

I am happy to say that the cincho quinine is all that you claim for it, and indeed it is more. I have used it largely in my practice this season, in intermittents, and it has not failed to accomplish all that I expected of it in a single instance. I have used the cincho with success in several cases where I could not the sulphate, on account of the stomach rejecting it. I find it produces much less constitutional disturbance; and in the same doses, the therapeutical effects are fully equal to the sulphate.

From J. J. H. Love, M. D., Montclair, New Jersey.

I have used this summer three ounces of the cincho quinine, and while I will say that it does not fulfil all my expectations, I must regard it as a valuable addition to our list of remedial agents. It will break up intermittent fever just as quickly as sulphate of quinine, and produces no headache or ringing in the ears. It is a splendid tonic in building up debilitated constitutions.

From McKisson & Robbins, Importers and Wholesale Druggists, New York, Oct. 2, 1869.

Messrs. J. R. NICHOLS & Co.:

Gents, — We have just received an order from one of our customers in Texas, for fifty ounces of your cincho quinine. We are requested by the parties ordering it to state to you, that the cincho quinine has proved its superiority over the sulphate in all febrile diseases, and that the physicians of their neighborhood are now prescribing it to the exclusion of the sulphate. We beg leave to add that this comes from parties whom we know to be first-class physicians and druggists.

From G. B. Bishop, M. D., Sheridan, New York.

I have used the cincho quinine and regard it as a valuable tonic, preferable to the sulphate of quinine. I think it to be a good agent in malarial diseases. Patients do not complain of the taste as they do of quinine, which is an important point.

From J. M. Aldrich, M. D., Fall River, Mass.

I have used one and a half ounces of the cincho quinine, and I think very favorably of its effects. In a case of intermittent fever (the patient from Tennessee), I found it to operate as well and as promptly as sulphate of quinine, without any unpleasant head symptoms. In no case have I discovered any unpleasant cerebral disturbance, as is often found in the use of the quinine.

From J. H. Frey, M. D., Perry, Iowa.

I have used several ounces of cincho quinine with the most complete success. I prefer it to the sulphate of quinine in intermittents, especially with children. I can strongly recommend it to the profession generally.

From Samuel W. Coons, M. D., Madison, Alabama.

The cincho quinine which I have used gave entire satisfaction. It has all the advantages you claim for it, and doubtless it will in time supersede the use of sulphate of quinine entirely.

From J. C. Ross, M. D., Lincoln, Illinois.

I have been using the cincho quinine in my practice in intermittents and remittents, and I think well of it. I believe it to be quite equal to the sulphate, with all the advantages which you claim for it.

From D. Shelby, M. D., Huntsville, Alabama.

I am delighted with the specimen of cincho quinine you sent me. I have used it successfully in cases of remittent fever, and shall soon order a good supply.

From J. C. Downing, M. D., Wapping Falls, New York.

I have used cincho quinine in eight or ten cases, and have reason to think well of the results. I give it as I do the sulphate, ten grains in five doses during the intermission, and five grains one or two hours before a paroxysm is due, and continue to give five grains once a week for three weeks. I shall continue to use it, and wish you to send me one ounce by mail.

From S. A. Butterfield, M. D., Indianapolis, Ind.

I have tried cincho quinine pretty thoroughly, and, for children especially, I think it of the greatest value as an anti-periodic and tonic. It has a comparatively pleasant taste when mixed with sugar, which is a point of much importance. I am not prepared to speak positively regarding its anti-periodic power when compared with sulph. quinine, but will do so at a future time.

From J. H. Beech, M. D., Coldwater, Mich.

I have used an ounce of cincho quinine in some obstinate cases of intermittent neuralgias and ague, and am happy to state that it has thus far sustained in full the anticipations raised by what you have claimed for it. Dr. S. S. Cutter, of this city, has an extensive general practice, and he informed me a few days ago that the cincho quinine was giving satisfaction.

From I. E. Swan, M. D., Mount Vernon, Ohio.

I find the cincho quinine a success. Children much prefer it to the sulphate. Inclosed is an order for a supply to be sent by mail.

☞ Druggists and physicians should remember that the salts of morphia are sold by *avoirdupois* weight in this country and England. The vials in which sulphate of morphia is usually sold, hold one eighth *of an ounce*, or a fraction less than fifty-five grains, *not a drachm*, or *sixty grains.* All drugs and chemicals, in commerce, are bought and sold by avoirdupois weight. Many druggists make a mistake in this regard, and hence we call attention to the matter.

BOSTON JOURNAL

OF

CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. IV.—No. 7. BOSTON, JANUARY 1, 1870. [FIFTY CENTS PER ANNUM. SINGLE NUMBERS, SIX CENTS.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, FIFTY CENTS PER ANNUM, IN ADVANCE.

All subscriptions begin and end with the current volume.

RECEIPTS.—A receipted bill will be sent by return mail to any subscriber who will enclose with his subscription a three-cent postage stamp, for return postage.

A list of premiums is offered to those who obtain subscribers.

Contents.

☞ Subscribers will remember that the volumes of the *Journal* commence and end upon the 1st of *July*, not January.

☞ Mr. GEORGE W. HEWES is Travelling Agent for the *Journal*.

Familiar Science.

THE DISTANCE OF THE DOG-STAR.

IN the November JOURNAL, under the head of "The Worlds in Space," we spoke of the distance of the Dog-star as so immense that its light takes twenty-three years to reach our earth. A correspondent finds a statement in a school manual of astronomy, that the time is "three years and eighty-two days," instead of twenty-three years, and he wishes to know "how the two authorities can be reconciled, or if there are typographical errors in either case."

The book which our correspondent quotes is often inaccurate in its statements, and entirely behind the times.

It is a fact, however, that even the best of recent authorities are sometimes found to disagree concerning the distances of the fixed stars. We have nowhere seen the distance of Sirius put so low as our correspondent states it, but Loomis ("Treatise on Astronomy," 1865) gives it as 896,803 times the sun's distance, equivalent to a "light interval" of 14.16 years; while Chambers ("Descriptive Astronomy," 1867) and Lockyer ("Elementary Astronomy," 1868) and several other recent writers give it as 1,375,000 times the sun's distance, equivalent to a "light interval" of 21.56 years. Now, the discrepancy between these two measurements is enormous, being more than 478,000 times the distance of the sun from the earth, or, in round numbers, more than forty-three *millions of millions* of miles — an interval that light, which can fly eight times round the earth in a *second*, must take more than *seven years* to traverse. Our first thought is, that if astronomers cannot make their measurements agree better than *that*, they must be either very careless or very stupid fellows. But let us look into the problem a little, before we pass judgment upon their solution of it.

How is the distance of a star measured? We shall not give a detailed account of the process, but simply attempt to show its general nature, and thus to convey some idea of the difficulties attending it. The distance of the star is found by *trigonometry:* in other words, astronomers use the same methods employed by land surveyors, and these methods are based on the measurement of angles. In any triangle, if we have two angles and one side given, we can, by means of trigonometry, find the other sides of the triangle. If, then, we wish to find the distance of a tower or a mountain-top which we cannot reach, we can do it by measuring accurately a line as a "base line," and then measuring the angles which lines drawn from its ends in the direction of the object make with the base line, or with each other. Knowing then one side of the triangle made by these three lines, as well as the angles of the triangle, we can calculate the length of the other sides, or the distance of the object from the ends of the base line. Beginning in this way, astronomers measured from point to point on the earth, until the shape and size of the earth had been determined; then, taking the diameter of the earth as a base line, the distance of the planet Mars was determined, and then that of the sun. Having obtained the distance of the sun (91,500,000 miles), we are in possession of a base line of enormous length, since the positions of the earth in opposite points of its orbit will be 183,000,000 miles apart. This is the base line used in measuring the distance of the stars, but their distance is so inconceivably great when compared with the base line, that the measurement of the angles of the triangle is a task of extreme delicacy and difficulty. The largest angle made at any fixed star, by lines drawn from the ends of this base line of 183,000,000 miles, is *less than two seconds*. If you wish to get an idea how small an angle of two seconds is, draw a triangle, one of whose sides is *one-tenth of an inch* long, and each of the others 860 feet long: the longer sides will make with each other an angle of two seconds. Or, if you wish to know what such an angle is upon the circle of the starry heavens, take the distance between the two "Pointers" in "the Dipper" (about five degrees), divide it into *nine thousand* parts, and one of those parts is equal to two seconds.

The angle formed in this way by lines drawn to the star from the ends of this base line of 183,000,000 miles, is called the *parallax* of the star. For certain reasons, however, the *half* of this angle (or that made by using the *radius*, instead of the *diameter*, of the earth's orbit as the base of the triangle), is usually taken as the parallax; and it is in this latter sense that we shall hereafter use the term.

Now, such is the nicety of astronomical measurements, that if a star has a parallax of *one second*, it can be accurately determined. By a somewhat different method a parallax of even the tenth of a second may be measured with tolerable precision; but it is only after a comparison of the results of repeated measurements that these infinitesimal angles can be determined beyond a doubt.

After thirty years or more of labor in this field of investigation, astronomers have found the distances of two stars pretty accurately, and have approximated to the distances of eight or ten others. The two whose distances we may say we *know*, are *Alpha Centauri* (a bright star in the southern heavens, which does not rise in the latitude of Boston), whose parallax is about .9 of a second, its distance 224,000 times the sun's, and its "light interval" 3.52 years; and 61 *Cygni* (a very small star in the constellation of the Swan), with a parallax of about .56 of a second, a distance 366,000 times the sun's, and a "light interval" of 5.77 years.

Among the stars whose distance is approximately known, is Sirius; and now let us recur to the enormous difference between the distances obtained by different observers, and see upon how minute an *angular* difference it depends. If the parallax is .23 of a second, as one authority makes it, the star is 896,803 times as far off as the sun, and its light takes only 14.16 years to

reach us; but if its parallax is .15 of a second, it is 1,375,000 times as distant as the sun, and its light must travel 21.56 years before it arrives at our earth. The inconceivably great difference in the results is due, as will be seen, to a difference of .08 of a second in the measurement of an angle! How small this difference actually *is*, the reader can figure out for himself, taking as a basis of his calculation what we have told him of the size of an angle of *two seconds*. It is an angular difference which would be represented by *the breadth of a human hair viewed at the distance of about 625 feet!*

We may add another illustration of the effect of a small error in the measurement of an angle upon the solution of an astronomical problem. It is well known to most of our readers, we presume, that the distance of the sun used to be reckoned as 95,000,000 of miles; but within a few years astronomers have quite generally agreed that this number is about 3,500,000 miles too large. This correction is based upon a correction of the value of the solar parallax, amounting to only about .4 of a second.

These things show that the astronomer deals with microscopic as well as with telescopic distances, and that the measurement of the latter is accomplished only by the most careful observation of the former. The subdivisions of the graduated scales which he uses are so minute that he actually has to read them by the aid of a microscope; while with his telescope he penetrates to regions of space so remote that the rays of light which he gathers up with his lenses must have left their source thousands of years ago. And so, also, in his measurement of *time*, he divides a second into a hundred parts, and, on the other hand, he computes cycles so vast that the completion of a single one exceeds sevenfold the entire period that man has lived on the earth.

THE CHEMISTRY OF LUMINOUS FLAMES.

Flame is burning gas. If a solid body appears to burn with flame, it can be proved that it has been first converted into a gas, and that it is the latter which produces the flame. If a solid substance, like anthracite coal, cannot be volatilized, it may become white hot in burning, but there will be no flame.

But some flames are pale and dim, yielding scarcely any light, while others are more or less brilliant. Why is this? Does it depend on the *heat* of the flame, as we might infer from the analogy of solid bodies; does the flame become brighter and brighter as it grows hotter — just as a piece of iron when heated up to a certain point begins to give out a dim red light, which grows whiter and more brilliant with the increase of temperature, until it almost dazzles the eye? On the contrary, we find that a flame, as in the case of a common spirit lamp, may be very pale, and yet very hot. If we burn a mixture of oxygen and hydrogen, we get but little light, while the heat is intense enough to melt almost every known substance. Iron and many other metals will burn in it, like wax in the flame of a candle.

But this same oxy-hydrogen flame, as it is called, may help us in solving our problem. If we hold a piece of lime in the midst of the burning gases, the flame, which had been so pale, becomes dazzlingly bright. A slight examination will satisfy us that the flame itself is really no brighter than before, and that the sudden increase of light is wholly due to the *lime*, which, instead of burning away in the fierce heat, merely becomes white hot and glows with a steady radiance so long as it is kept at that high temperature.

In this case, then, the flame becomes luminous because a *solid* is *heated white hot* within it. Have we here the key to all cases of the kind? Until a very recent day all scientific men were ready to answer this question in the affirmative. They laid it down as a rule, without exceptions, that the light of flames is due to solid bodies or solid particles intensely heated. The light of all the substances commonly used for illumination was explained in the very same way. Indeed, there is no essential difference in the flames of a candle, an oil lamp, and a gas-burner, or in the way in which they are produced. All are alike *gas* flames, since only gases burn with flame; and the gases are all essentially the same, being *hydrocarbons*, or compounds of hydrogen and carbon. The main point of difference is that, in the candle and the lamp, the gas is made *where it is burned*, by the volatilization of the tallow, wax, or oil; while in the case of the gas-burner it is made in the retorts of the gas-works, from bituminous coal, by a very similar process. In every case, the illuminating property of the gas depends upon the simple fact that *the hydrogen and carbon do not burn at the same time, but in succession.* The hydrogen burns first, and the particles of carbon thus set free delay for an instant in the flame and become white hot, before they burn away into a transparent, invisible gas, carbonic acid. The interval is almost infinitesimally brief, but as fast as the carbon particles burn away and their evanescent glow ceases, fresh ones take their place, and thus the light is continuous.

In this way, as we said above, it has been supposed that all luminous flames must be explained. Frankland, however, has recently shown that there may be very bright flames in which no solid particles are present. He burned a jet of hydrogen in a tube of oxygen, and, gradually increasing the pressure upon the gas to twenty atmospheres, he found the brilliancy of the flame to increase with the pressure. At a pressure of ten atmospheres, a burning jet of hydrogen an inch in length gave light enough for reading a newspaper at a distance of two feet from the flame. He also found that carbonic oxide, which usually burns with a very pale flame, burned very brightly under great pressure. In the first case, the product of the combustion was *water*, which must have existed in a gaseous state in the flame; in the second case, the product was *carbonic acid*, which must also have been a gas. In both cases, the gas in the flame was rendered more dense by the pressure. If metallic arsenic be burnt in a stream of oxygen gas, it yields a dazzling white flame, though neither the metal itself nor the product of its combination with oxygen can remain solid at the temperature of the flame. The same is true of sulphur and phosphorus when burned in oxygen. The latter burns with a brightness which is almost blinding, and yet the phosphoric anhydride (or phosphoric acid) which is produced is so readily volatilized that it can hardly exist as a solid, even at the extreme outer surface of the flame.

These facts, and many others of the same sort, have compelled scientific men to modify their former theory of the luminosity of flames, and to say that the light may sometimes be due, not to the presence of solid particles, but to that of *dense gases or vapors*, intensely heated. Frankland's experiments appear to show that, as a rule, the denser the vapor, the brighter will be the flame. It is a confirmation of this view that a flame becomes more luminous if the pressure of the air upon it is increased, and less luminous if that pressure is diminished. The flame of a common spirit lamp grows bright in condensed air; and a candle gives much more light at the foot of a high mountain than at its top, though the rate of combustion is nearly the same in both cases.

Are we to explain the light of an ordinary gas-flame in this way? Frankland believes that we should do so. Under the combined influence of heat and oxygen, the hydrogen gradually separates from the carbon, whose atoms, so to speak, shrink more closely together. The compounds thus formed are perfectly volatile, and their vapors are necessarily very dense. "To the presence of such compounds," he says, "I am inclined to ascribe the luminosity of the gas-flame. I believe that the lighter hydrocarbons when exposed to the intense heat of the flame are transformed into dense vapors which have the luminiferous character of arsenic-vapor or phosphorus-vapor." He does not presume to assert that the decomposition of hydrocarbons in the flame is never complete — in other words, that particles of elementary carbon are never separated — but he is fully satisfied that "the incandescence of solid particles is not the chief condition of luminosity," but that the light is "mainly due to the ignition of dense hydrocarbon vapors."

Certain obvious facts connected with gas-flames are perfectly consistent with this new theory, while they are not easily explained under the old one. The flame from a common fish-tail burner is so transparent that the smallest print can be read through any part of it without the least difficulty. We find, too, that the edge of such a flame gives just as much light as its flat side does. If the light proceeded from solid particles, the most luminous part of the flame ought to be more or less opaque; and as such particles would obstruct the light of those behind them, the edge of the flame ought to be less bright than the side.

On the whole, we must admit that some of the phenomena of luminous flames can be satisfactorily explained only by Frankland's theory, and that probably it furnishes the correct explanation of nearly all such phenomena.

CORAL ISLANDS.

The Rev. Charles Kingsley, well-known as a novelist, poet, and preacher, is likewise an enthusiastic naturalist. His little book entitled "Glaucus" is a delightful seaside companion for those who are interested in zoölogical study. The following extract is from one of his papers in "Good Words for the Young," and will be found entertaining by the young folks, if not by their elders:—

But how does the coral ever rise above the surface of the water and turn into hard stone? Of course the coral polypes cannot build above the high tide mark; but the surf which beats upon them piles up their broken fragments just as a sea beach is piled up, and hammers them together with that water hammer which is heavier and stronger than any you have ever seen in a smith's forge. And then, as is the fashion of lime, the whole mass sets and becomes hard, as you may see mortar set; and so you have a low island a few feet above the sea. Then sea birds come to it, and rest and build; and seeds are floated thither from far lands; and among them almost always the cocoa-nut, which loves to grow by the sea-shore, and groves of cocoa palms grow up from the lonely isle. Then, perhaps trees or bushes are drifted thither before the trade wind; and entangled in their roots are the seeds of other plants, and eggs or cocoons of insects; and so a few flowers and a few butterflies and beetles set up for themselves upon the new land. And then a bird or two, caught in a storm and blown away to sea, finds shelter in the cocoa-grove; and so a little new world is set up; in which (you must remember always) there are no four-footed beasts, nor snakes, nor lizards, nor frogs, nor any animals that cannot cross the sea. And on some of those islands they may live (indeed there is reason to believe they have lived) so long, that some of them have

changed their forms, according to the laws of Madame How, who sooner or later fits each thing exactly for the place in which it is meant to live, till upon some of them you may find such strange and unique forms as the famous cocoa-nut crab, which learned men call *Bergus latro.* A great crab he is, and walks upon the tips of his toes a foot high above the ground. And because he has often nothing to eat but cocoa-nuts, or at least they are the best things he can find, cocoa-nuts he has learnt to eat, and after a fashion which it would puzzle you to imitate. The sailors used to say that he climbed up the stems of the cocoa-nut trees, and pulled the fruit down for himself; but that, it seems, is not quite true. What he really does is this: when he finds a fallen cocoa-nut, he begins tearing away the thick husk and fibre with his strong claws; and he knows perfectly well which end to tear it from, namely, from the end where the three eye-holes are, which you call the monkey's face, out of one of which, you know, the young cocoa-nut tree would burst forth. And when he has got to the eye-holes he hammers through one of them with the point of his heavy claw. So far, so good; but how is our friend to get the meat out? He cannot put his claw in. He has no proboscis like a butterfly to insert and suck with. He is as far off from his dinner as the fox was when the stork offered him a feast in a long-necked jar. What, then, do you think he does? He turns himself round, he puts in a pair of his hind pincers, which are very thin, and with them scoops the meat of the cocoa-nut, and so puts his dinner into his mouth with his hind feet. And even the cocoa-nut husk he does not waste; for he lives in deep burrows which he makes like a rabbit, and being a luxurious crab, and liking to sleep soft in spite of his hard shell, he lines them with a quantity of cocoa-nut fibre, picked out clean and fine, just as if he was going to make cocoa-nut matting of it. And being also a clean crab, as I hope you are a clean little boy, he goes down to the sea every night to have his bath and moisten his gills, and so lives happy all his days, and gets so fat in his old age that he carries about his body nearly a quart of pure oil.

BAROMETRIC SPRING.

J. H. Temple of Framingham, Mass., sends us the following account of a singular spring in that town:—

There is a never failing spring of pure water upon our farm, which has the peculiarity of overflowing with a sudden rush just before a rainfall. It matters not what the season of the year may be; summer and winter, in wet weather, and in the time of severest drought—all at once the water comes pouring from this spring, often flooding the intervale through which it is discharged; and within thirty-six hours thereafter a rainfall comes.

The hidden arteries which supply this spring have been traced to some rocky highlands, with swampy depressions, a fourth of a mile from the place of outflow. The main artery has been tapped by a well thirty rods from the spring, and is there twenty-four feet below the surface.

In wet seasons, the spring sends forth a stream sufficient to fill an eight-inch pipe. After running about one hundred rods this stream loses itself in a swamp. In the dry season this stream loses itself in a course of fifty rods. It diminishes in volume regularly, as other neighboring springs do, with the progress of the summer, or a drought, except as already indicated.

In this region the springs failed steadily through July and August; and I was led to watch my prophet spring with a good deal of interest. On Sunday, September 5th, the discharge was unusually sluggish, scarcely enough water flowing to fill a two-inch pipe, and reaching only about forty rods from the spring. Monday morning, the 6th, it was pouring forth a little torrent, having more than doubled in volume, and filling its channel for a distance of not less than eighty rods. But the sky was brassy, and the heat intense, with no atmospheric indications of a change of weather. Tuesday morning the overflow continued; the clouds had overcast the sky, and at 11 A. M. rain began to fall, which continued till 3 P. M. Wednesday morning, the spring was discharging about the same quantity of water as on Monday, showing that it is not immediately affected by a copious shower.

Arts.

CHEMISTRY OF THE EXPOSITION OF 1867.

The display of chemical products at the Paris Exposition, was large and fine, not excelled in importance by any other department. It was noticeable that, while not many *new* processes or products were exhibited, there had been a steady improvement in the old. The United States, of course, made comparatively little show, but the rivalry among the English, French, and German manufacturers was quite brisk. We, however, are as much interested in the subject as any nation, since we are largely dependent upon Europe for many important articles, which we can, and some time probably shall, make for ourselves. We have lying upon the table before us, the Report on the Industrial Chemistry of the Paris Universal Exposition, drawn up by Dr. J. Lawrence Smith, one of the United States Commissioners. We know of no one better fitted than Dr. Smith, to write such a report, and we have taken great pleasure in reading the very interesting book of one hundred and forty-six pages, that embodies the result of his observations. Dr. Smith seems to have aimed rather at a resumé of the present condition of the chemical manufactures, than at a description of what was actually exhibited at the Exposition. Consequently, it is of general interest, and we shall, therefore, in the following paragraphs, give our readers a brief summary of its most important points, arranging them under such heads as best suit our purpose.

MANUFACTURE OF SULPHURIC ACID.

In his introduction, Dr. Smith says that the acids and the alkalies constitute the substructure of the chemical arts, and that of this substructure sulphuric acid is the corner stone; so, in his report, he devotes considerable space to considering its manufacture. There has been no essential change in the process of making oil of vitriol for the last ten years. The well-known method of burning sulphur to sulphurous acid, and then completing its oxidation with the aid of nitrous compounds, is still the only one in extensive use. The sulphur for conversion into sulphurous acid is obtained from several sources, mostly from Sicily sulphur and pyrites. Sulphur has been and is mined extensively in Sicily; formerly, very nearly all the sulphuric acid made was derived from it. But from various causes, the price has been kept so high, that manufacturers have been obliged to seek other material from which to obtain the cheap acid, so necessary in the arts, and "now not more than one-tenth of this acid is made directly from sulphur." Within fifteen or twenty years, in France and England, pyrites has very largely taken its place. In the United States, Sicily sulphur is still in ordinary use; attempts have been made to employ pyrites, but with what success we are unable to say. Other sources of sulphur are from coal gas and soda waste; both are of importance, not only from the value of the sulphur obtained, but, also, because in each case waste products of other manufactures are utilized.

It will hardly be desirable for us to enter into any description of the chambers, furnaces, etc. We will only remark, that if pyrites is burned, larger chambers and more nitrous gases are required, and of course, a peculiar furnace. Dr. Smith appends to his report full plans of vitriol works. Concentration of the weak acid of the chambers to 1.70 sp. gr. is still carried on in the ordinary leaden pans; but we notice that, in England and Belgium, glass vessels are to a large extent replacing platinum stills for the final concentration. This is due to the high price of platinum, and, also, to the better quality of the glass retorts now made. In France, platinum stills are almost altogether used. The Report makes particular mention of those manufactured by Johnson and Matthey, of London. This firm seem to have surpassed all their rivals in working platinum. Their work is peculiar from the fact that they do not solder the seams or joints with gold, as do the others, but burn the sheets together with the oxy-hydrogen blow pipe.

SODA MANUFACTURE.

No essential change has ever been made in Leblanc's original process. The most important recent improvement in connection with it, is the utilization of the waste. This waste has always been a very serious annoyance. It collects in great quantity, is so acted upon by air and moisture that it emits noxious gases, and at the same time large amounts of sulphur are thrown away in it. A great part of the sulphur in this waste is now extracted by a process contrived by a German chemist, named Mond. Air is blown through the moist mass; oxidation at once commences, by which the insoluble sulphide of calcium is changed into soluble compounds; lixiviation with water extracts these; and from the solution sulphur is precipitated by an acid. The residue has considerable value as a fertilizer. All the soda of commerce is made by Leblanc's process, excepting the comparatively small amount prepared from cryolite.

Cryolite is a fluoride of aluminium and sodium. It is decomposed by heating its powder with six equivalents of caustic lime; caustic soda, aluminate of soda, and fluoride of calcium being formed. The first two are dissolved in water, and the alumina precipitated from the solution by carbonic acid, leaving carbonate of soda in solution. The alumina is worked up into salts (sulphate and acetate) for the use of the dyer. By boiling with fifteen equivalents of lime and water, the alumina combines with part of the lime, to form an insoluble compound, leaving only caustic soda in solution.

Though soda and its compounds are made in enormous quantities, yet, as every chemist knows, it is difficult to obtain even at an exorbitant price *pure* carbonate of soda, and especially hard to get *pure caustic* soda. Perfectly pure caustic soda is, however, now prepared from metallic sodium at a cheaper rate than by any other method.

This is a singular fact, but it goes to show how largely sodium is now manufactured. Johnson and Matthey of London, make this soda. It is sold at one dollar and seventy-five cents, gold, per pound, including bottle and packing case.

We expected to find in Dr. Smith's Report something about the preparation of both sodium and potassium, but he does not allude to it.

POTASH MANUFACTURE.

Dr. Smith describes at some length Balard's process for obtaining potash from the mother liquors of sea-salt works. The process is a beautiful one, but hardly of general interest, and therefore we will not enter into any account of it. Of more interest are his remarks upon the Stassfurt deposits, from which great quantities of potash salts are now obtained. In our November number, however, we laid before our readers a more extended account of them than we could give here.

FATS; SOAP AND CANDLE MAKING.

Stearine candles and candle stuff were exhibited in great variety at the Exposition. The principal differ-

ence in candle stuffs noticed by the reporter, was that some were a little more mottled than others. This he considers to be due, in part, to the method of saponification followed. Saponification by lime gives a smaller yield of the best candle stuff with a high melting-point, and a large quantity of oleic acid of superior quality; while the saponification by sulphuric acid and distillation furnishes a larger amount of candle stuff of second quality, and a smaller amount of a poorer liquid oil. One or the other of these processes is employed, according as the demand is for a candle of the finest kind at a high price, or for a cheaper one of inferior quality. Therefore, in France, Germany, Russia, Italy, Spain, and Portugal, the lime saponification is in general use, while in Holland, England, and America, the sulphuric acid is the commonest. Both these processes are described in books on technical chemistry. Palm oil is successfully decomposed by simple distillation with water. This process is largely carried on at the well-known Price Candle Works.

De Milly has contrived a method of saponification by sulphuric acid, without distillation. He makes a very fine quality of beautifully white candle stuff. There is no tarry matter formed, but the liquid oleic acid is of a brown color. From the latter can be made a good brown soap, or it can be rendered white by distillation. The operation is as follows: — The fat is melted and heated to 120° C. (248° F.) and then agitated with six per cent of strong sulphuric acid. In two or three minutes, the mixture is poured into boiling water, which dissolves the sulphuric acid and glycerine, and the fatty acids, of a dark color, float on the surface. The peculiar advantage of this method lies in the fact that the coloring matter of the fatty acids is entirely soluble in the liquid portion; so that by cold and hot pressure the solid acids are obtained perfectly white. Three-fourths of the solid fat acid present is thus obtained, and the remaining fourth can be distilled, but is, of course, of inferior quality.

This very simple process is much preferable to either the lime or the sulphuric acid saponification; for since there is no carbonization, the yield is greater, and at the same time but comparatively little apparatus is required. De Milly has patented his process in this country, but it has not yet been put into practice here, though it promises to be very successful. Under the head of Soap, Dr. Smith says he has nothing new to mention, except the use, for making soap, of the brown liquid fat resulting from the above-described method of De Milly. This soap has a very dark color, but possesses as much detergent power as any other.

[TO BE CONTINUED.]

CURIOUS FACTS ABOUT COPPER.

A REPORT has lately been made to the French Academy of Sciences upon the exemption from cholera of men engaged in working with copper. Statistics obtained under the supervision of the commissaries of police, and therefore to be relied upon as accurate, show that wherever the manipulation of copper was carried on, the workmen have almost invariably escaped unharmed; and, moreover, that the exemption was in exact proportion to the degree in which the metal was handled by the men. During the epidemics of 1865 and 1866, the number of deaths was only 3 out of every 10,000 adults employed in the working of copper. Of goldsmiths, silversmiths, and watchmakers, the mortality was 1 to every 719 employed; among founders, lamp-makers, and workers in bronze, imitation jewelry, and copper utensils, it was 1 to 2,000; while among opticians, makers of mathematical and musical instruments, dry polishers, stampers, and turners, there was not a single death among the whole number of 5,650 persons.

Further testimony in favor of the preservative action of copper was supplied by the society known as the Bon Accord, which was founded in 1819, and entirely composed of workers in bronze, and the medical registers of which are thoroughly well kept. During the whole of the five visitations of cholera, this society, the members of which were scattered in quarters where the epidemic raged with the greatest virulence, had not only not had a single death, but had been called upon to pay only for 106 days of sickness, divided among ten members of the society. Facts supporting the theory were also supplied from other sources. The conclusion drawn from this statement was, that if further inquiries established the truth of the theory, exceedingly valuable results, from a hygienic point of view, would follow.

Since the publication of these facts, a M. Adeline has invented what he calls an "anti-cholera tissue," a woven fabric in which a certain quantity of copper wire is introduced for the purpose of serving as a prophylactic. The contrivance appears to be indorsed by respectable scientific and medical authorities in France.

A writer in *Cosmos* gives some facts in regard to the preservation of wood by solutions of salts of copper. He has in his possession wooden water-wheels which have been in use for more than 1,500 years for removing water from a copper mine. These wheels are about eighteen feet in diameter; and an analysis by M. Payen of a portion of the wood shows that it is perfectly sound and is partly converted into a compound of cellulose and copper.

It appears, moreover, that the decay of stone may be prevented by the black oxide or the salts of copper. M. Robert has proved that the decay of granite, marble, limestone, sandstone, and other building stones, is largely due to a very minute lichen (*Lepra antiquitatis*); and that this cryptogamic plant does not grow upon the stone pedestals of bronze statues, or those parts of buildings to which bronze or copper ornaments are fastened. In such cases, the stone is protected by the salts of copper, which are gradually formed under the influence of the weather, and are washed down by the rain; these compounds being poisonous to the plants. Abundant illustrations of these facts were found among the old buildings of Paris, and they are very important on account of the length of time which has elapsed since the protective action of the copper compounds began.

BRICKS FROM GAS-COAL ASHES. — Walls of remarkable lightness, porosity, and dryness may be built cheaply of bricks made from the ashes of the coke derived from gas-works. The ashes, after being taken from the retorts, are spread on the surface of a clean floor; they are then finely pulverized, and ten per cent of slaked lime, together with a small proportion of water is intimately stirred and incorporated with them. After a rest of twenty-four hours, the mixture is made into bricks by the ordinary process. These bricks are immediately transferred to the drying-sheds, where a few days of exposure renders them fit for use.

WATER-PROOF CLOTH. — To make water-proof cloth take two pounds and four ounces of alum, and dissolve it in ten gallons of water; in like manner dissolve the same quantity of sugar of lead in a similar quantity of water, and mix the two together. The cloth is immersed for one hour in the solution, and stirred occasionally, when it is taken out, dried in the shade, washed in clean water and dried again. This preparation enables the cloth to repel water like the feathers of a duck's back, and yet allows the perspiration to pass somewhat freely through it, which is not the case with gutta-percha or India-rubber cloth.

USE OF ZINC-WHITE AS A PAINT. — No substance containing lead should be used in connection with zinc-white. Instead of the ordinary *boiled oil*, an oil should be used which is prepared in the following manner: 200 pounds of linseed oil are gently boiled, first for some five or six hours alone, and, next, boiled again along with 24 pounds of coarsely broken-up peroxide of manganese for at least twelve hours; in this manner, a very quickly-drying linseed oil is obtained, which is eminently fit for the purpose of being used with zinc-white and other zinc colors. The inventor of this process lays stress upon the use of old linseed oil, and also upon the care to be taken with the boiled oil, which, unless carefully kept from access of air, becomes thick in a very short time. The boiled oil so prepared ought not to be used in painting with zinc-white by itself alone, but should be mixed, in quantities of from 3 to 5 per cent, with the raw linseed oil used to mix up the paint.

WOOD STAINING. — White woods become dark, like walnut, if they are painted over with a concentrated aqueous solution of permanganate of potassa, which should be tepid at the time. The wood of pear and cherry trees is rapidly stained; white woods, as for instance, the acacia (*Robinia pseudo-acacia*), resist a longer time; and resinous woods, like fir, are more difficultly acted on. The rationale is that the permanganate of potassa is decomposed by the woody fibre; brown peroxide of manganese is precipitated and fixed by the potassa, which is afterward removed by washing with water. The wood, after having become dry, is varnished, and is then not readily distinguished from naturally dark woods.

THE END OF THE HORSE. — When the horse falls, he is bled, and his blood is preserved for the use of the dyer. The mane and tail are next cut off for the manufacture of sieves, hair cloths, and bow-strings for the violin; the shoes are taken off for the nailer; the hoofs are cut off for combs and various other kinds of horn-work, and a portion of the feet goes to the glue-maker; the skin is stripped off for the tanner, who converts it into excellent leather for boots, harness, etc., and the collar-maker finds it, in its rough state, the best material for cart harness. The flesh is then cut up for carnivorous beasts in menageries, or for dogs, and, though without knowing that they are hippophagi (a club of horse-eaters, who regularly advertise their club days), some of our fellow creatures are regaled in the cheap eating-houses of great cities with delicate bits of carcass in the form of *patés*, pretended beef-steaks, or soup. When the flesh and fat have been removed, the stomach and intestines are laid aside for machine straps and strings for musical instruments, and are often sold, for the last purpose, as the best Naples cords: the ribs are turned into buttons and children's toys; the large round bones serve for tweezers, whistles, ferrules, knife-handles, cups and balls, dominoes, etc.; the large, flat bones are of use to the toymen for many things; even the teeth are useful, when polished, to the dentist, and for many purposes for which ivory is required. The bones of the head are either consumed in heating furnaces or crushed for manure. The remainder of the carcass is burnt, and by this process produces ivory-black, soot-black, and valuable manure. And from the fat is extracted a coarse oil which is used by mechanics. — *Manufacturer and Builder.*

Agriculture.

UNDERDRAINING.

[*From Dr. Nichols's Address at Greenfield, Mass.*]

WATER and sunlight are the great agencies upon which the farmer depends for the success of his crops. What a vast amount of anxiety and despondency is caused by these agencies, and yet they are among the greatest blessings vouchsafed to the race! The excessive heats of summer will parch our fields, and wring out from every tree and shrub the last drop of moisture, and the persistent penetrating rains will drown our cereals, and soak our fields until they are saturated like a sponge. We can do something to mitigate the evils of excessive heat or drought, but we can do much to avert those caused by water. We can drain our soil, and thus carry away in hidden channels the excess of water which, if allowed to remain, would chill or suffocate every root, fibre and tendril upon which plant life depends.

I can hardly manifest too great earnestness upon a subject of so much importance to farmers as underdraining. In this country we are not sufficiently awake to the great benefits which flow from it: our faith is not strong enough to lead to the adoption of a system of land-drainage which would overcome one-half the losses occasioned by late springs and wet seasons, and which would bring into high tilth thousands of acres now lying waste and valueless. I have tested upon my farm the value of underdrains, not only upon low lands, but upon high lands. Two years ago I resolved to experiment upon a hill or elevation, thirty feet above my meadow, and I placed in position tiles, so as to afford a full and free outlet for the water which is so lavishly poured upon us in Spring months. Some of my farmer friends predicted the worst possible consequences to the crop upon that field, and confidently looked for wilted leaves upon the corn stalks during the dry months of July and August. But in this expectation they were disappointed. No wilting came, although the heat was fervid and the clouds gave no rain. The corn planted the first year withstood the drought better than the crops situated upon lower land, and very much better that those upon other fields of equal elevation. It was earlier in starting, grew more vigorously, the product was heavier, and it was harvested much sooner in the autumn than other crops. The second year the same results were observed in the growth and maturation of wheat; and I have no doubt that the improvement is a permanent one, that in a series of years the cash value of the improved crops will greatly outweigh the expense incurred in draining. It is certain that even our uplands can be greatly improved by drainage.

What is the philosophy of such apparently paradoxical experiments? It is easily understood. The first great benefit, of course, comes from conveying away superfluous water at the season when the seeds are placed in the soil. All soils, high and low, are then filled with water struggling to escape by percolation and evaporation, and the farmer must wait until it slowly disappears before putting in his seed. In this there is not only a loss of time, but often it carries crops so late into Autumn that early frosts nip and destroy them. This form of benefit is readily comprehended; but the inquiry comes up, "If drains carry away the *unnecessary* water in the *Spring*, why will they not carry off the *necessary* water of *Summer?* Why do they not leach the soil at the very time when every atom of moisture is needed to feed the growing grains and grasses?" It may be said, in reply, that drains are incapable of removing water which is of service to plants; it is only when it is in *excess* and detrimental, that the work of removal goes on. They are active only in wet summers upon elevated lands; their useful services only then come in play. In dry summers they keep dry soils moist. There is in such seasons reversed action going on. Instead of water coming out, air is passing in, and as even the hottest air holds a vast amount of water, it only needs to be brought in contact with refrigerating substances to produce a copious precipitation of water. All of us have observed large drops of water form upon and trickle down the sides of our ice-pitchers in the hot days of summer. This water is condensed from the warm and apparently dry air, which comes in contact with the ice-cold surface of the vessel. This will illustrate the way in which the soil is moistened through the agency of drain pipes. The earth, at a distance of one foot from the surface, is several degrees cooler than the air above, and consequently when air passes in through the open ducts, it parts with its hidden moisture, and the vapor is diffused through the soil. Water readily travels through burnt clay, when unglazed. This we know from the fact that if we build a water cistern of bricks, and omit to cover the inside with hydraulic cement, the water will run out as fast as it runs in. The best possible water filter that can be devised, is constructed by building inside of a rain-water cistern, lined with cement, a brick chamber, which will rapidly fill with water by passing through the bricks. In its passage it is deprived of all impurities and becomes pure and excellent — suitable for all household purposes. A pump passing into the chamber will bring this pure water to the desired point above, and the supply will prove abundant for all ordinary wants. This form of filtration will continue in action for years. I have spoken of the device here for a two-fold purpose: first, to call your attention to a most excellent and convenient way of filtering cistern water; and second, to illustrate the method of action of the ordinary drain tiles. The water passes through the pores in the tiles, and drops are constantly falling from the top arch, and passing up from the bottom through the whole length of the tubes, while resting in wet soils. The minute orifices do not become obstructed as we naturally suppose they would. I have known a brick filtering chamber to supply pure water copiously for a period of fifteen years, and doubtless they will continue in satisfactory action for fifty years.

TEA CULTURE IN TENNESSEE.

THE tea plant is in successful cultivation some ten miles from Knoxville, Tenn., where it has been raised for the past ten years. The plants were originally obtained through the Agricultural Department at Washington, in the year 1858.

The plant is an evergreen shrub, growing to the height of some five feet. It is perfectly hardy, and needs no protection from frosts. It bears an abundant crop, with beautiful, fragrant flowers, in October. The seed is not matured until the following season.

Captain James Campbell, who has made the experiment of raising the plant, has not attempted its cultivation on a large scale, but, as he expresses it, "just enough to keep the family in tea." Good judges, who have tried the Captain's tea, pronounce it to be not inferior in fragrance and flavor to the imported Young Hyson. It seems quite probable, then, that "Young America" may yet live to see Young Hyson thoroughly naturalized on Uncle Samuel's plantation.

IMPROVEMENT OF GRAIN BY NATURAL SELECTION.

AT the Exeter meeting of the British Association, Mr. Hallet, of Brighton, read a paper giving an account of his experiments upon the improvement of grain by applying the principles of "natural selection." By this method he succeeded in obtaining a grain of wheat, which, when sown, produced a whole multitude of stalks, each of which bore a magnificent ear well filled with grain. The quality is maintained by the descendant seeds, and the produce is thus increased more than a hundred fold.

Mr. Hallet lays down the following principles as the result of his observations:—

1. Every fully developed plant, whether of wheat, oats, or barley, has an ear superior in productive power to any of the rest on that plant.
2. Every such plant contains one grain which proves more productive than any other.
3. The best grain in any plant is found in its best ear.
4. The superior vigor of this grain is transmissible in different degrees to its progeny.
5. By repeated careful selection the superiority is accumulated.
6. The improvement, after a long series of years, reaches a limit.
7. By still continuing to select, the improvement is maintained, and practically a fixed type is the result.

SUNFLOWERS AS DISINFECTANTS.

EXPERIMENTS in France and Holland have shown that sunflowers, when planted on an extensive scale, will neutralize the pernicious effects of exhalations from marshes. This plan has been tried with great success in the ferny districts near Rochefort, France; and the authorities of Holland assert that intermittent fever has wholly disappeared from districts where the sunflowers have been planted. It is not yet determined what effect the flower produces on the atmosphere; whether it generates oxygen, like other plants of rapid growth, or whether, like the *coniferæ*, it emits ozone, and thus destroys the organic germs of miasms that produce fever.

PROGRESS OF FRUIT CULTURE.

THE following is an extract from the admirable address of Hon. Marshall P. Wilder, President of the Pomological Society, at the recent session of that Society in Philadelphia: —

Mark the amazing increase of the small fruits. Take, for instance, the strawberry. Within the memory of many of this assembly, we were dependent almost wholly upon the wild species of the field, or the few which had been transplanted to our gardens. It is only about thirty years since the first attempt, we believe, was made on this continent to raise from seed a new and improved variety — thanks to the enterprise of Mr. Hovey, which gave us a fruit that has stood the test for a whole generation of men. Compare the small, dry, seedy, red and white wood-strawberries of our youth with the numerous larger luscious varieties which have come to notice in our day. Not only have the latter increased to hundreds of varieties within this time, but the quantity produced is in a still greater ratio. What would our fathers have said at the despatch from a single railroad station in the Western States, where fifty years ago the emigrant had scarcely set his foot, of one thousand bushels of strawberries daily to market, or from another depot on the unoccupied lands of New Jersey taken up within fifteen years, a similar quantity sent to the New York market daily; or, still more remarkable, from Norfolk, in Virginia, where seventeen years ago, the cultivation of this fruit had not commenced, and from whence during the present season three millions of quarts have been sent to the Northern markets!

Thirty years ago we possessed only two good varieties of the raspberry, the red and white Antwerp; now we have numerous fine kinds; and where a man thought himself fortunate to gather a saucerful, it is raised, as by our friend William Parry, of New Jersey, by hundreds or thousands of bushels for the market. So of the currant and blackberry. Of the latter not a single variety had then been introduced into our gardens or catalogues; now we have many new kinds, and the product is equally great.

The ingenious methods of gathering, preserving, and packing of fruits, and the improved means of safe transmission to distant markets, are among the most important advances in this new era. To such perfection have these been brought, that not only our small, tender fruits come to us a hundred or a thousand miles, in good order, but the grape and the pear travel from the Pacific to the Atlantic coast. While penning this address, pears and other fruits have come to our own hands from California, in perfect condition; and, to add to our surprise, the pears of that State are finding a market in Japan. Our cheap and convenient postal facilities for the transmission of seeds, scions, and plants, promoting the introduction of new fruits into the remotest parts of the land, are such as no other nation has ever enjoyed, yet not more than commensurate with the demands of our extensive territory; and we trust the day is not distant when we shall have equal facilities for such reciprocal advantages with the whole world.

THE GROWTH OF TREE-TRUNKS.—A paragraph has been round the scientific papers stating that a French naturalist has been measuring the tree-trunks in a forest, and has found them all broader in the east-west than in the north-south direction; the causes of the unsymmetry being ascribed, not very obviously, to the rotation of the earth. Well, another French arborist has been similarly gauging the trees in the neighborhood of Toulouse, and he finds that the greatest swelling of their trunks is toward the east-south-east point of the compass. The explanation offered by this second investigator is more philosophical than that of his predecessor. He refers the deformation to the early morning sun, which warms the easterly parts of the tree more suddenly than the rest, stimulates the flow of the sap, which grows sluggish during the cool of the night, and draws up the nourishing moisture from the soil in greater abundance on the excited side than on those portions of the trunk where the warming is more gradual and its effects less active. Naturally, increased vitality of one side, be it animal or plant, results in development, or larger growth of that side. There are traditions of some plants turning their flowers toward the sun; the truth may be that the sun only promotes the growth of those blossoms upon which it sheds its direct warmth. As Dulong said, every degree of the thermometer entails a law of Nature. —*Every Saturday.*

A GOOD IDEA.—In Iowa the planting of trees is encouraged by law. Every acre of forest trees planted releases taxation for ten years on one hundred dollars valuation, and for each acre of fruit trees planted tax is exempted on fifty dollars valuation for five years; the same for shade trees and hedges along the highways. There are now maple forests in several counties, and sugar is made where fifteen years since was nothing but prairie grass and hazel shrubs.

Boston Journal of Chemistry.

BOSTON, JANUARY 1, 1870.

☞ Any person sending us the names of *three* new subscribers, with full pay enclosed, will be entitled to a *fourth copy of the* JOURNAL *gratis*. For *five* new subscribers, we will send the *petite microscope*. For *eight*, we will send one set of Twenty Small Carpenters' Tools in a Hollow Handle—a most convenient article. For *ten*, we will send a copy of Dr. Nichols' book, "*Chemistry of the Farm and the Sea*," or Messrs. Rolfe and Gillet's "*Handbook of the Stars*," or the "*Handbook of Chemistry*," by the same authors. *These are all beautiful and instructive books*. For *twenty* subscribers, we will send the "*American Naturalist*," published by the Peabody Academy of Science, Salem, for one year. This is one of the most interesting and useful publications in the country, devoted to Natural History. Or a Boy's Tool Chest, 13 inches long, 8 inches wide, 8 inches deep, with a complete set of Carpenters' Tools,—Saw, Plane, etc. (The express charges on the Chest to be paid by the receiver.) For *thirty* subscribers, we will send the *Naturalist* and the "*New England Farmer*," an agricultural paper, published in Boston. For one hundred and twenty-five subscribers, a Silver Case American Watch. Price, $30.

☞ Premiums are allowed only upon *new* subscribers, not on renewals of subscription by old subscribers.

☞ Physicians, students, clerks in drug stores, young lads etc., who may be induced to solicit subscribers, will find the labor much easier than they anticipate. The interesting character of the *Journal*, together with its low subscription price will lead almost every one of intelligence to become its patron. It is the only journal of practical chemistry published in the United States.

☞ Correspondents are particularly requested to give their names in full, with their Town and State; and, in case of change of residence requiring a corresponding change in the mailing of their papers, to give not only the new address, but the old one also.

☞ We have no complete files of either Vols. 1, 2, or 3; of Vol. I. (originally issued bi-monthly), we have only Nos. 4, 5 and 6 (January, March and May, 1867); of Vol. II. (monthly), we have Nos. 2, 4, 5, 7, 8, 9, 10, 11 (August, October, November, 1867, January, February, March, April and May, 1868); of Vol. III. we have all the numbers *except* 11 and 12 (May and June, 1869). All the other numbers are out of print, and it is impossible for us to furnish them.

Of the numbers mentioned we have a few copies left, which we will forward to our friends, at the following prices, viz: Vol. I., three numbers, twenty-five cents; Vol. II., eight numbers, fifty cents; Vol. III., ten numbers, fifty cents. Vol. IV. has been stereotyped as issued, and we are able to furnish back numbers since July 1869, to any extent. Price, single copies, six cents, six copies for twenty-five cents.

THE NEXT VOLUME OF THE JOURNAL.

AT the commencement of the next volume (Vol. V.) of the JOURNAL in July, it will be enlarged to sixteen pages, with twelve pages of reading matter. Several important improvements will be made in the arrangement and style of the paper, and a new department, that of *microscopy*, will be introduced. Several of the best observers and most accomplished makers of microscopes in the country will contribute to this department. Arrangements have been made with gentlemen well known in the scientific world, to furnish articles upon science, of a practical, familiar character, and no effort will be spared to make the JOURNAL even more useful and acceptable to all classes of readers than it has been. These additions and improvements will involve no radical change in the tone or general conduct of the paper. It will remain the same wide-awake, reliable, practical, useful journal of familiar science, which has become so popular all over the country. *It is the journal of science for the million, the people's journal, the journal for the family*, and it must always remain so. The price will be one dollar per year, payable in advance.

All our friends who now stand upon our books as paid at the old rate beyond the commencement of Vol. V., will receive their journals till the date already given in their printed addresses, as we shall make no alteration in their accounts with us; but hereafter to all persons remitting only fifty cents for a year's subscription we shall send the back numbers of the present volume, and credit them as paid to July, 1870.

THE JOURNAL FREE FOR SIX MONTHS.—To all new subscribers to Vol. V. of the JOURNAL, commencing next July, we offer as a gratuity the remaining numbers of the present volume. Upon the receipt of *one dollar*, the price of Vol. V., we will enter the name of the subscriber from January 1870, thus making the subscription equal to one and a half years. We hope this liberal offer will induce large numbers to become our patrons. For nearly four years we have published the JOURNAL without any remuneration, the low price of subscription hardly allowing us to meet expenses. Now, the thousands of readers who have been and are our fast friends, who have received the JOURNAL at a price less than it could be afforded for, can do us a great favor by making an effort to extend its circulation. If each of our present readers will obtain *one new subscriber* for the present volume, or for the next, they will confer a great favor. How easily and readily this can be done! Every one has some neighbor or friend, who would be benefited by reading the JOURNAL, and who would become its patron if his attention was only called to it. Will you not put this number in your pocket and show it to a friend, obtain his name, and forward it to us?

KILLING BY KEROSENE.

THIS enlightened form of slaughter goes bravely on throughout the length and breadth of the land. Kerosene may soon boast that it has killed, not merely its thousands, but its tens of thousands. It is a kind of murder which appears somehow to be rather popular than otherwise, for though there are laws against it, nobody takes the trouble to see them enforced. Burning fluids, which might be *warranted* to take fire or explode at temperatures to which they are almost sure to be exposed in ordinary household management, are sold in almost as many shops as spirituous liquors are, and with far greater impunity. Indeed, if our State Constabulary were half as active in ferreting out the venders of illegal kerosene and kindred fluids as in finding where contraband beverages are retailed, they would soon put an end to the nefarious traffic, and possibly be doing quite as good service to the community—even if we take a teetotaller's view of the value of what they are *now* doing.

If we lived under a monarchical government, we might expect that a law of this kind would be enforced; but in a "free country" like ours any interference with the inalienable right of burning ourselves to death in horrible ways is viewed as inconsistent with republican principles. We wonder that somebody has not questioned the "constitutionality" of this law; perhaps it is merely because the law is a dead letter, and therefore not worth the trouble of such a protest.

In England there appears to be a disposition to enforce the law against the storage and sale of oils which give off inflammable vapor at a temperature of less than 100° F. The *Pharmaceutist* for November, 1869, says:

"We call the special attention of those engaged in the sale or use of petroleum to the regulations which the law requires to be observed in reference thereto. The serious accidents which have recently occurred, including the extensive destruction of shipping at Bordeaux, have caused the authorities to put the provisions of the law into operation with more than usual strictness, and it behooves those who are in any way subject to the operation of the law to consider the nature and extent of their liabilities. . . .

At a recent meeting of the Court of Aldermen in the City of London, Alderman Wilson stated that a considerable quantity of the more volatile petroleum spirit was being sold, the vapor of which ignited much below that specified in the Act, and he wished it to be understood that those dealing in such spirit were liable to a fine of £20, which fine would be rigidly enforced. He had just had such a case brought under his judicial notice, and, the defendant being a widow, he mitigated the fine; but it was the intention of the magistrates in future, in all cases, to inflict the full penalty."

In France, the temperature of minimum inflammability is fixed by law at 43° C. (110° F.); but M. Garnier, in *Les Mondes* for November 11, 1869, argues that experience has sufficiently shown that this temperature is too low. He urges that it should be raised to 82° C. (180° F.) This is possible in France, but it would never be tolerated here. What reasonable chance of blowing or burning ourselves up, with oils whose vapor would not take fire below 180°? The benighted victims of an imperial government may submit to this despotic restriction of the right of suicide by fire, but free-born Yankees would never bear such arbitrary infringement of their personal liberty. If we want to offer up human sacrifices to the Moloch of Kerosene, shall officious philanthropists be allowed to prevent it? Sanitary reform is diminishing the causes of mortality quite fast enough: shall not naphtha and petroleum be left us a little longer?

LIGHT AND LIFE.

IT has been proved by recent researches in France that the *red* rays of the spectrum are those to which the important physiological function exercised by the sun on plants is exclusively to be ascribed. The leaves act as analyzers of the white light which falls upon them; they reject and reflect the green rays, and thus get their natural color. If plants were exposed to green illumination only, they would be virtually in the dark. The light which the vegetable world thus refuses to absorb is precisely that which is coveted by animals. Red, the complementary color of green, is that which, owing to the blood, tinges the skin of the healthy human subject, just as the green color of plants is the complement of that which they absorb.

These facts have been fully stated and illustrated in a paper read by M. Dubrunfaut before the French Academy of Science; and from them he deduces certain practical suggestions. All kinds of red should be avoided in our furniture, except curtains. Our clothes, which play the part of screens, should never be green. This color should predominate in our furniture, while the complementary red should be reserved for our raiment. He also dwells upon the salubrious influences of sunshine. He mentions cases of patients whose broken constitutions were restored by continued exposure to the sun in gardens where there were no trees; and gives an account of four children that had become weak and sickly by living in a narrow street in Paris, but regained their health under the influence of the solar rays on a sandy sea-coast.

KENOSA LAKE AND LAKESIDE FARM.

"Kenosa! o'er no sweeter lake
Shall morning break or noon cloud sail;
No lighter wave than thine shall take
The sunset's golden veil."—*Whittier*.

THE poet Whittier, in his beautiful poem "Kenosa Lake," justly describes this charming sheet of water, and the picturesque surroundings. The lake is situated in the suburbs of the city of Haverhill, Mass., and is distant from Boston thirty-two miles. "Lakeside" farm, consisting of about one hundred acres, is upon the margin of the lake, and embraces very much of the delightful scenery in wood, hill, and dale, which renders the lake so famous.

Very many of our readers in this city and vicinity will be pleased to know that they can look upon this beautiful scenery without leaving the city limits. During the past autumn, our friend Thos. Hill, the artist, well known as the painter of the great picture, "The Yosemite," visited Lakeside and took sketches of the scenery; and these he has combined in one large and

magnificent painting, which presents a charming view of the lake and farm.

This painting, with its dress of autumn foliage and autumn sky, is one of the most successful attempts to place upon canvas the quiet, picturesque scenery of New England, ever made by an American artist. It will remain upon exhibition at Childs & Co.'s, Tremont street, a few weeks, where our many friends and readers, if they desire, can see it.

EDITORIAL NOTES.

A Big Bridge. — A French engineer has made plans for a bridge across the British channel, from Dover to Calais. The distance is about eighteen miles, and there are to be ten spans of nearly two miles each. The piers are to be built on shore, and floated to the appointed spot by means of buoys, and then sunk and firmly fastened. The piers are so constructed that the water flows through them with little resistance, and they are also to be provided with staircases, up which, should a vessel run foul of the structure, the mariners can ascend and take the first train home. The plan of the proposed bridge has been approved by the best engineers, both in France and England, and a model of it is to be erected over the lake in the Bois de Boulogne at Paris.

A Nice Cargo for Rough Weather. — On Saturday, September 11th, the steamship "Lady Wodehouse," on her way from London to Dublin, encountered a heavy gale. Part of the cargo consisted of petroleum and lucifer matches. The lashings of the petroleum casks gave way, and the casks being dashed against the chests of matches, immediately ignited and then, rolling toward the centre of the vessel, set fire to the sides of the saloon, and two of the lifeboats, the flames rising with fearful rapidity above the deck. The scene, it is said, lasted three hours; but happily, by the judgment of the captain and the untiring exertions of the crew, the fire was subdued. But the flames broke out a second time, when the petroleum casks and the lucifer matches were thrown overboard, and the ship, after contending fruitlessly with the storm for twelve hours, put into Dungeness, where most of the passengers were landed.

Hygienic Theory and Practice. — The *Hartford Post* states that "four students have died from disease contracted in the damp and unwholesome dormitories of Yale College." If this be true, it is a sad satire on the practical bearings of our college system. We ourselves have seen a college with a good gymnasium, and unventilated recitation rooms; with lectures on physiology, and dormitories that are merely small closets without a window. We have no doubt that the description will apply to more than one of our "seats of learning."

Zinc for Water Tanks. — A writer in a foreign scientific journal says that water kept in zinc tanks or vessels, or collected from roofs covered with zinc, is invariably contaminated with that metal, and that the use of such water for culinary purposes is highly injurious to health. Zinc vessels, for such purposes, should be coated with asphalt varnish or some iron pigment.

On the Track of the Cholera. — The French Academy of Medicine has sent an embassy to the shores of the Caspian Sea, to find out, if possible, why the malignant cholera takes that route in its travel from east to west.

Vegetable Extracts. — A happy idea has occurred to a Frenchman; namely, to apply to the vegetables in ordinary use for culinary purposes a process which has long been successfully employed for vegetables used in pharmacy. He extracts the juices of the vegetables by strong hydraulic presses, and concentrates the same by evaporation in vacuum pans. An extract is thus obtained which is suitable for making soups and sauces. It is said that the process has been fairly tested, and that it is perfectly successful. We see no reason to doubt it.

Bronzing of Copper. — Immerse articles made of copper in melted sulphur, wherein lamp-black is kept suspended, and they get the appearance of bronze. They can be polished, if desired, after the process.

Is there Heat in Moonlight? — Lord Rosse decided that there *is*, but M. Marié-Davy came to a different conclusion, as we stated in the last Journal. It appears now that, on repeating his experiments, with some variations, M. Davy finds that the moon gives out a perceptible amount of heat. He therefore retracts his former statements. M. Volpicelli, and several other *savants*, have arrived at similar results by independent experiments. We may then consider it settled that moonbeams are not "*all* moonshine," but that there is a certain mixture of calorific rays with the luminous ones.

Arsenic in Soda. — The chemists have a pleasant way of finding poisons in all sorts of things in everyday use. Fresenius has discovered that the crystallized carbonate of soda, as manufactured at the alkali works, often contains a perceptible amount of arseniate or arsenite of soda. The arsenic undoubtedly comes from the sulphuric acid used in converting the common salt into sulphate of soda (which is one stage in the soda manufacture), and the sulphuric acid gets it from the *pyrites* out of which it is made. Few specimens of native pyrites are free from arsenic, and some contain a considerable quantity.

Galvanic Education. — The applications of electricity are daily increasing, and it would be rash to say what it may *not* be made to do "one of these days." The medical galvanists — mostly quacks, of course, — are claiming to have made new discoveries of late. One of them, in France, declares that he can make weakly and idiotic children bodily and mentally strong. The dull boy may thus be brightened by having his brain stirred with electricity. Galvanism is said to be better than whipping to quicken the aptitude for learning; or, if we may indulge in an atrocious pun, *a salt and battery* are better than *assault and battery* as an educational stimulant. Schoolmasters will do well to make a note of this. It is proposed to light railway tunnels with the electric light: why should not the road to learning be illuminated by the same means?

The Self-sacrifice of Scientific Experimenters. — A man engaged in scientific researches often has to do very dirty and very disagreeable work. Dr. Flint, whose investigations on the excretory function of the liver have been honored with a favorable report by a committee of the French Academy of Sciences, remarks in the preface to the third volume of his "Physiology" (just published by the Appletons), that the experiments connected with these investigations "are so repulsive and difficult that there is little likelihood of their being extensively verified." It is said that certain ardent students of physiology are now engaged on "experimental helminthology," which, in plain English, is the cultivation of parasites in the human body, and in other animals, for the purpose of tracing their habits and the effects they produce. It is hardly probable that *these* experiments will be voluntarily verified by many scientific students.

Bavarian Schools for Brewing. — The superior quality of the Bavarian beer is well known. It appears that at Munich and Augsburg there are schools in which everything that relates to the brewing of beer is taught, practically and theoretically; and the value of the training given may be inferred from the fact that among the students are natives of almost every European country, as well as of the United States. It is safe to say that these institutions are *not* managed after the fashion of some of our scientific schools and agricultural colleges, where the proportion of practical to theoretical teaching is pretty much like Falstaff's "half-penny-worth of bread" to an "intolerable deal of sack."

New Things that are Old. — Is there anything new under the sun? The bicycle seems to have been known in China two centuries ago, and some forms of the velocipede were probably seen even earlier in Europe. In the ancient painted glass of the church of Stoke Pogis (the churchyard of which, by the by, was the scene of Gray's famous "Elegy") may be seen a youth riding the wheeled horse amid a throng of admiring spectators. The paddle-wheel for boats is seen on the Assyrian marbles; and it is now suggested that the pyramids of Egypt may be built of artificial stone, made in the same way as that which the French have used on the Suez canal. It is well known that no stone like that of the pyramids is to be found anywhere in the vicinity, and this fact lends plausibility to the supposition that it is a manufactured material.

Sulphur in Louisiana. — Deposits of pure sulphur have been found in Louisiana. If they are extensive, the discovery is of more importance to the State than that of rich gold fields would be. All the branches of chemical manufacture which depend on sulphur will follow in the train of the discovery; and the making of sulphuric acid, soda ash, muriatic acid, bleaching powders, and a hundred other compounds largely used in the arts will directly and indirectly give employment to thousands of workmen, and add greatly to the commerce and the wealth of the region. It will also be the means of developing other mineral resources of the South, which at present are comparatively worthless. The deposits of manganese and saltpetre will become more valuable; and the increasing demand for artificial fertilizers may more readily and more cheaply be met.

Venom of Toads. — Shakespeare says that "the toad, ugly and venomous, wears yet a precious jewel in his head." In our day we have come to believe that the venom is as mythical as the jewel; but several foreign *savants* have been looking into the subject and assert that the matter exuding from the parotid region of the toad acts as a poison. Some of the savages of South America use this toad poison instead of the *curara*.

A Brief Solace for the Decapitated. — Claude Bernard has found that, if oxygenized blood be injected into the arteries of the neck immediately after decapitation, warmth and sensibility return, the eyes become animated, and display such perception that, if an object be shaken before them, they will wink, as if to avoid injury.

A Gigantic Gun. — A twenty-inch gun, to carry a ball of 1100 pounds, with a charge of one hundred and forty pounds of powder, has been made in Russia. It is destined for a two-turreted monitor, now building under the direction of Rear Admiral Popoff (an appropriate name!) of the Emperor's suite.

The Faraday and Graham Medals. — The Faraday medal of the Chemical Society is to be struck in palladium, and a quantity of this rare metal, sufficient for the medals of at least ten years to come, has been

presented to the society by a metallurgical firm in England.

A medal of the alloy of palladium and hydrogenium was struck, not long before the death of Graham, to commemorate his discovery of the latter metal. It bears on one side the effigy of Queen Victoria, and on the other the name of Graham and the words "Palladium — Hydrogenium, 1869." The medal contains 900 times its own bulk of hydrogenium, and since the thickness of the medal is 1 millimetre, a layer of hydrogen of a height of nearly 1 metre is condensed in that thickness of metal.

Saccharimetrical Congress at Berlin. — The modern tendency to organized action in every department of science, art, and — everything else, is curiously illustrated by a meeting which lately took place at Berlin. Some twenty-five chemists, whose chief business is the investigation and analysis of raw sugars, did there convene, and appoint special committees, — one to prepare a standard sample of pure sugar, another on the manufacture of perfect and uniform optical saccharometers, and so on, — and this is to be the beginning of a series of such sweet meetings. It is not stated whether the congress wound up with a dinner. If it did, no doubt there was plenty of confectionery and *bonbons*, and *eau sucrée* was probably the favorite beverage.

LITERARY NOTES.

When we recollect the "Annuals" that used to be the only handsome gift-books for the holidays, we have to admit that in this line of literature, if in no other, there has been a decided advance in our day and generation. Instead of sentimental trash, unworthy of even the meanest type and paper, we now see the best things of the best authors honored with the most exquisite art and taste of the printer and the engraver. And this year, it is a significant fact that one or two of the most beautiful books issued for the holiday season are of a scientific character. It is hardly possible in a brief notice to do justice to a work like "The Universe; *or the Infinitely Great and the Infinitely Little*," translated from the French of Pouchet, and published by Scribner & Co., of New York. We can do little more than call the attention of our readers to it, as a popular treatise on natural science which, even in the plainest typographical dress, would be of the highest value for the matter it contains; and which superadds to this intrinsic merit the very perfection of mechanical execution and pictorial embellishment. It gives you "apples of gold in pictures of silver," — a panorama of the animal and vegetable worlds, of the earth, sea, air, and sky, which is no unworthy reflection of the beauty of Nature herself. As an able critic has remarked, the book might well be entitled "Science Made Fascinating," since one cannot turn its leaves without longing to know more of the subjects of which it treats — the artists have so managed to captivate the eye and enlist the attention. We shall have occasion to refer to it again, and to draw some material from its rich and varied contents.

Another beautiful book, from the same publishers, is "*Bible Animals*," by the Rev. J. G. Wood, well known as a popular writer on natural history. In this large and admirably illustrated volume, we have "a description of every living creature mentioned in the Scriptures, from the ape to the coral." It has an equal interest for the student of zoölogy and of the Bible. The young and those of maturer years will alike find it attractive and instructive. The illustrations are not merely exquisite specimens of wood engraving; they are accurate pictures of the animals they represent taken from drawings by the best artists or from photographs brought home by travellers. But we must leave this book, like the other, to tell its own story to the eye; our limits do not allow us to describe them adequately.

Hours at Home, the excellent monthly published by Scribner & Co., deserves well the success it has won. The article on "Comfort in its Relations to Physical Culture" is of itself worth the price of the December number. "Twenty Minutes under the Knife" is a vivid picture of a surgical operation, both objectively and subjectively considered. "Bible Animals" and "Birds of Passage" are likewise excellent.

Messrs. W. A. Townsend & Adams, of New York, deserve much credit for their reprint of the *Chemical News*, the best paper of its class in England. They give all that is in the English edition, and add an American supplement, which has a value of its own. They are also the publishers of the "uniform American edition" of *Braithwaite's Retrospect*, which, by an arrangement with the eminent editors, they issue simultaneously with its appearance in London. That the work is invaluable to the physician, it is superfluous to state: it needs no indorsement from us at this late day. And we may say the same of the *Physician's Handbook* for 1870, edited by Drs. W. and A. D. Elmer, published by the same house. Its convenience and utility as a *vade mecum* for the medical practitioner are too well known to make any commendation from us necessary. *The "American Journal of Obstetrics*," though little more than a year old, has been so ably edited, that its reputation is established and its success insured. It is, moreover, one of the handsomest of our medical magazines.

"*Nature*" is the title of a weekly illustrated journal of science, published by Macmillan & Co. Its object is "first, to place before the general public the grand results of scientific work and scientific discovery, and to urge the claims of science to a more general recognition in education and in daily life; and, secondly, to aid scientific men themselves, by giving early information of all advances made in any branch of natural knowledge throughout the world, and by affording them an opportunity of discussing the various scientific questions which arise from time to time." The list of contributors includes almost every scientific man of eminence in Great Britain, and the opening numbers are all that we should expect from such a corps of writers. The paper is furnished in this country at the New York agency of the publishers, 63 Bleecker street.

"*Cyclopædic Science Simplified*" is the title of a handsome volume by Prof. Pepper, published by Scribner, Welford & Co. As a popular presentation of the leading facts and theories of physics, including all the latest discoveries, together with all the more important practical applications of the science, it is a model book. Chemistry also has a fair share of attention; and in both divisions of the book there is a profusion of experimental illustration, and of pictorial illustrations as well. "The Boy's Playbook of Science," and "Playbook of Metals," by the same author, have long been favorites with the young, and we have known decidedly old boys to read them with interest; but now they are unfortunately behind the times. This new book will more than fill the place of both, and deserves to be more than twice as popular.

Haydn's "*Dictionary of Dates*" is one of the most valuable books of reference ever published. Even if you have a dozen cyclopædias, you cannot do without it. There are things which you may search for in vain everywhere else, and yet find them here; and many things which you might find elsewhere are got far more readily and conveniently in Haydn. An item which it would take you half an hour to dig out from a volume on physics, or chemistry, or history, you find in half a minute in its alphabetical place here. If you want to know when the great earthquake at Lisbon occurred, turn to the word *Earthquake*, and you have a list of all the famous ones from B. C. 425, when Eubœa was made an island by one, down to those of 1868. If you are curious about the Cock-Lane Ghost, or Cod-liver Oil, or Coffee, you will find the leading facts and dates concerning each in their proper pigeon-holes on a single page. Under Photography, or any branch of science or art, you have every important process or discovery concisely recorded and dated; and so with all facts pertaining to the civil, military, and religious history of every race and country on the earth. The work has gone through thirteen editions in England, and the Harpers have now reprinted it here, with much new matter pertaining to the United States, which adds to its value for the American reader.

The same house has issued Hartwig's "*Polar World*," a popular description of man and nature in the arctic and antarctic regions. It contains all the original work, with additional chapters, and one hundred and sixty illustrations. It is every way preferable to the foreign edition — which can rarely be said of an American reprint.

Greenwood's "*Wild Sports of the World*," is another of the Harpers' recent issues — a book which will be in great demand with the boys about this time, and one which we can cordially recommend for them. And we may say the same of Du Chaillu's "*Lost in the Jungle*," which is just out. Both as a writer and a lecturer, the noted "gorilla hunter" is justly popular with the young.

Home Printing. — If a man wishes to be his own printer, he can learn how to do it in our advertising columns. The "Novelty Press" will not enable him to dispense with the Journal; but it will prove all that it claims to be, whether for work or play.

Medicine and Pharmacy.

M. VELPEAU.

(Continued.)

As a lecturer, Velpeau is not remarkable, though he is sufficiently fluent and pleasant. Some new comers find his French easy to understand; but though he does not mumble his words and splutter, as M. Roux did, yet there are several in Paris who speak very much plainer and better than he. I could cite Trousseau and Maisonneuve for examples. His tone is somewhat monotonous, and however enlivened by an occasional dry jest, there is neither much eloquence nor any brilliancy. But Velpeau's attraction is his fame, his knowledge, and the perfect flood of light which his vast experience enables him to throw on every subject. You feel that he utters opinions which you can set down as rules and axioms for your guidance in practice. He speaks *ex cathedra* upon every topic; his words are golden, for they flow refined from a vast mass of material collected during years of earnest toil, — a toil directed by an enlightened understanding, and guided by an acquaintance and comparison, with not simply the stores of the past, but with the improvement of modern research.

Old and antiquated notions, and an adherence to early impressions, however false, cling to some who are only distinguished by age, arrogance, and imbecility. But Velpeau, clothed in the ancient heavy armor of the veteran, still bears about him the keen and trenchant sword, as sharp and polished as that of any youthful

champion around him. He may hedge himself in with precedent and experience, but he is constantly re-examining his precedent, and weighing and comparing his experience with that of others, whilst none contribute more fresh additions to them than himself. As his English compeer across the channel, old Liston, said: "Age is not the test of experience; the possession of the greatest number of well assorted facts on any particular subject, whether they be got in five years or in fifty, constitutes experience."

Though Velpeau has a finger quite awry and misshapen, from some wound gained during the pursuit of his profession, I believe, yet this does not at all interfere with his manual dexterity. Not priding himself on it, he is yet ambidextrous. I shall be excused for saying that however skilful in this respect, he cannot surpass our countryman, Mott, who uses either hand, sinister or dexter, with the most perfect indifference to himself. I have seen Mott dissect out a tumor over the wrist of a patient, at a surgical clinique in New York, when he employed his left hand alone; the individual did not lose an ounce of blood, and there were the vessels flowing just beneath, which had been evaded with a nicety surprising to the beholder. We know that, with a few rare exceptions, including some operations on the eye, the surgeon had always better avoid display, and manipulate with the usual and most natural member.

Verily, there is a charm and an attraction about surgery, which deceives and captivates the young, the inexperienced, and the unwary. It operates directly upon the senses. There is a brilliancy and a decision about the movements of the glittering knife, which is entirely irresistible. It does its work so directly, suddenly, and without appeal. The sight of the sudden gush of life-blood welling up from the heart itself, has something about it which stimulates and excites; so that most men start to be surgeons as they do to be metaphysicians, but when they are past thirty they find they have been guilty of an expensive blunder, for the proportion of their medical to their surgical cases are as ten to one, and time and years are wasted in the attempt to make a Velpeau or a Malgaigne, when they might have been much more respectable and distinguished as a Trousseau, Bouillaud, or a Louis.

It neither requires talent nor genius to wield the knife, for the heavy and the phlegmatic, the stolid and the dull, operate when they cannot prescribe, and excise and amputate when they cannot cure. Traumatic injuries and morbid growths are rare in number and slow in formation, whilst medical cases are frequent and come thick and fast, at the same time they demand more time and care for their relief. To be a great *surgeon*, however, in the enlarged application of the term, requires all the qualities of the mere operator, as well as those of the judicious medical man; but there must also be the material to give experience, which only falls to the lot of a very few, even in the largest and most populous cities.

Among his peers, if peer he has, Velpeau is *facile princeps*. See him standing amid his gowned associates, as for example, when Orfila died, and his body was brought by them into the Church of Saint Sulpice, or when he walks into the Academy of Medicine, or sits around the table at the Ecole de Medicine, when they are examining by *concour* that fine band of talented young Frenchmen contending for places. Hear how many of them will quote him, Malgaigne, Nelaton, and Roux, and see how queer and characteristic he looks all the while. I always smile when I watch Velpeau!

His hand was sick last year, and it was curious to observe how the Internes flocked around it of a morning,—how the sisters, in white caps, brought flaxseed, and the nurses flew for laudanum, and everybody offered their services, whilst old Velpeau disdained them all, and quietly dressed it himself. He never had it done at home, as everybody else would, by some member of his household; but, like a surgeon, he kept it to be taken care of by men in the midst of that theatre, where it had daily, for so many years, been performing such feats. I often looked on and smiled at the fun. I think, on one occasion, he did let one of them tie it up when he got through, and I presume it will be traditional, or like an heirloom in the man's family.

Singular to relate, this ambitious acquirer of professional lore does not speak English. Like most of his countrymen, he is content with the French, which they think everybody either does or should understand, and if they do not that is simply their loss. One morning, winter before the last, he stopped two or three of us on the stairs, to assist in translating what a raw Irishman said, who was attempting to obtain a certificate of six weeks' attendance upon the surgical clinique.

Velpeau has received a notice in the "*Biographie Universelle des Contemporains*," published as far back as 1834, from which I gather and translate a few particulars (see fifth and supplementary volume).

"Alfred Armand Louis Marie Velpeau, Chevalier of the Legion of Honor, etc., is one of the most striking examples of what can be effected by energy of character, particularly when united to a happy natural facility. He was born in 1795, at Bréche, a small hamlet, eight leagues from Tours. His parents were poor but honest. After some medical studies in his native place, and in the hospital at Tours, he came to Paris soon after 1818, with four hundred francs, minus his travelling expenses. He lodged at seven francs per month, and expended ten sous (half-franc) daily for his meals. He was soon crowned at the *Ecole Pratique*, and nominated aid in anatomy. He gave private courses in anatomy, surgery, and obstetrics. Before 1830, he had triumphed six times at the *concour*, out of ten essays, and he was nominated surgeon to the Hospital La Pitié."

It would be needless for me to mention in detail his subsequent successes, or the list of works which he has written. Justly admired by the civilized world, with which his fame as a surgeon and physician was coëxtensive, when he died one of the great lights of the age was extinguished, and he is lamented by thousands in every land, who were guided by his precept or taught by his example. His genius, his aptitude for scientific investigations, the practical cast of his mind, coupled with his capacity for labor, placed Velpeau at the very summit of his profession in the most enlightened capital of Europe. There, for a great number of years, he was the chief centre of attraction for every one who visited France with a view to medical improvement.

CHLORAL.

In the October number of the Journal, a brief description was given of a new hypnotic, or anæsthetic, suggested by Dr. Liebreich, of Berlin. Since that time, we have patiently waited to learn what we could by observation and experiment regarding the nature and value of the new claimant to notice in the medical world. From a chemical point of view, what is chloral? Chloral is trichloromethylhydrocarbonoxyd, according to the German chemists, and if this name is not sufficiently long, they have another, which contains a few more letters. Chloral is one of the numerous bodies discovered by the great chemist Liebig many years ago, and is prepared by passing well dried chlorine gas through *perfectly pure* alcohol, for many hours, or as long as it is absorbed. The crude product is subsequently mixed with three times its bulk of oil of vitriol, and distilled at a gentle heat, and the distillate is required to be again distilled over quicklime. This process is the original one, but since the demand for chloral has become large, two new processes have been discovered by which the agent is manufactured much more readily and cheaply. Chloral is an oily, colorless liquid, which, when brought in contact with the sense of smell, is so acrid as to cause the tears to flow freely. It has a specific gravity of 1.502, and it boils at 95° C. It mixes in all proportions with water, and also with ether and alcohol. Chloral in itself is so unstable or liable to spontaneous change, that it is not suited to medical uses. When it is brought in contact with water or aqueous vapor, star-shaped crystals are formed, which are the hydrate of chloral. The hydrate is the form in which the agent is now in the hands of medical men for trial.

Chloral hydrate forms a hard, white, crystalline mass, quite soluble in water, and when pure has no smell of chloride of carbon, hydrochloric acid, or other odor foreign to the penetrating, acrid odor of chloral itself.

Hydrate of chloral is a very dangerous agent to employ in an *impure* state, as the usual or natural contaminating bodies are all deleterious or poisonous in their influence upon the animal economy. Among them may be named chloride of carbon, chlorous acetylene, etc. Some specimens which have come under our notice, gotten up by *enterprising* pharmaceutists without requisite chemical knowledge, are of a very dubious character, and in no sense represent the agent in its integrity.

Chloral belongs to that class of bodies of which chloroform is a member. The variation in chemical constitution is apparently slight, as the comparison of formulas show.

Chloroform, C_2HCl_3
Chloral, $C^4Cl_3HO_2$

It is apparent that chloral, when brought in contact with alkaline bodies, must suffer decomposition and split up, forming new bodies, prominent among which is chloroform. A theory like that of Liebreich, which led him to experiment with chloral and trichloracetic acid, was a natural but a bold one. If chloroform was the only product of the chemical change resulting, when these agents were introduced into the circulation, the experiments would have been less hazardous; but in addition to this body, formiates and carbonates of the alkalies must be liberated or formed. The researches are, in every respect, interesting in animal chemistry, and the results certainly demonstrate one important fact,—that very strange and anomalous bodies may have their birth and exist in the vital current, without serious disturbance to its normal condition.

The question whether the human organization, when made to subserve the purposes of the alembic in the laboratory, is capable of splitting up bodies, and of appropriating the new compounds as therapeutic agents, was a novel one; and although we cannot regard it as having been positively answered, yet some new ideas have been awakened, and valuable results must follow. We do not yet know how chloral produces its remarkable hypnotic effects upon the system, although the weight of testimony preponderates in favor of the theory, that the resultant agent, chloroform, does the work. The number of careful and well conducted trials with chloral, abroad and at home, have not been numerous enough to warrant the expression of any opinions regarding its positive value, but it is safe to say that it promises to be a great accession to materia medica. If it proves to be an unsafe agent, or inefficient, or of little practical use, still this will not in the least tend to dissipate the conviction that we are very near to some important discoveries in the department of therapeutical chemistry. These discoveries bear especially upon a class of agents which must stand to the race as do ether and chloroform, in conferring blessings beyond our powers of estimation. Suffering humanity needs a certain and safe remedy for producing sleep, and relieving pain. The want of healthful, restful sleep is causing so great mental distress to thousands that death itself is coveted as a relief. Oh, what a boon to the world would be the agent which had power to *force* the worn and jaded brain of the nervous and watchful to calm repose! The blessing would be even greater than anæsthesia has conferred. To the discoverer, we will build a monument higher than any that has hitherto been reared upon our earth.

The hydrate of chloral is given, dissolved in water, in

doses of ten, twenty, or sixty grains. It is also used hypodermically with safety and success. At present the price is somewhat a bar to its free employment, but soon we shall be able to furnish it at such low prices as will place it within the reach of all.

SOME NEW TESTS.

FOR IRON AND COPPER. — An alcoholic tincture of logwood constitutes a test for these metals of unrivalled sensibility. The hæmatoxylin combines with either iron or copper, immediately producing a pure blue color resembling that of the iodide of starch. The tincture is best prepared by macerating 12 or 15 parts of fresh thin shavings of logwood in 100 parts of alcohol. The alcohol should be previously purified by digestion on quicklime, and distillation from a glass retort. On adding a score of drops of this tincture to 200 cubic centimetres of water, free from iron and copper, the liquid becomes yellow if carbonic acid predominates, or rose-violet if the earthy or alkaline bicarbonates are present. If a clean iron wire be then introduced, the color will be seen to change in the space of one or two minutes, blue striæ forming round the metal and passing to the bottom.

FOR ARSENIC AND ANTIMONY. — When arsenetted and antimonetted hydrogen are made to pass over iodine, they form iodides of arsenic and antimony. This reaction may be made use of in toxicological investigations. For this purpose, when Marsh's apparatus is used, a small quantity of iodine should be placed in that portion of the tube where, commonly, the metallic mirror is made apparent; that part of the tube is gently warmed, so that the iodine coats the tube; and the gas is then made to pass, care being taken to keep the tube somewhat warm. Should the gas contain arsenic, a yellow-colored mirror will be at once observed; when the gas contains antimony, an orange-colored iodide of that metal is formed. The iodide of arsenic yields, when volatilized, yellow-colored vapors, while the vapors of iodide of antimony are of a deep red hue.

FOR IODINE. — Mix 100 grammes of water with 1 of starch and 1 of nitrite of potassa. Boil the mixture for five minutes, and, after cooling, pour it into a bottle. It can be kept thus for years. When required for use, take 10 c. c., add one single drop of hydrochloric acid. Take as much as a pin's head in size of the dry salt to be tested for iodine, place it in a clean porcelain capsule, and add one drop of the test-fluid last mentioned. When no iodine is present, no coloration ensues; but the least trace of iodine gives rise to a well-defined blue color. The liquid test-fluid, after addition of the acid, keeps quite well in a properly-stoppered small bottle.

UNDER THE KNIFE.

THE doctor continues rapidly deepening the gash, which was made from four to five inches long and two or three inches deep at the very first cut of his scalpel. As he cuts, he continues his clinical lecture, and explains why I feel so little pain. He says that "the nerves of sensation are most closely distributed all over the surface of the body, and that, therefore, the skin is the most sensitive part; in cases like this, when once the skin is cut through, the patient feels little pain from the deeper cuts of the knife; this is one reason why a good surgeon always makes a long slash, or a 'free incision,' at the very first touch of his instrument, that the pain may be, as much as possible, over at once, and that there may be no necessity for any after hacking and haggling; a clean cut heals very kindly, and an inch or two of it, more or less, is generally of not much matter. Once get through the outer envelope of the body, and the patient, while you are cutting through the subjacent tissues, feels little or no pain, except when —"

What! *What!!* WHAT!!! IS THIS?

A sensation as if a gallon of melted lead had been poured into my wound, and instantly permeated every artery and vein in all my body; as if I were out naked in a rain of boiling liquid caustic; as if I were in a shower-bath of melted brass; as if boiling pitch had been dashed upon my quivering skin, and were being peeled off, bringing with it each and every hair from all my body, and as if a million of fine cambric needles at a white heat had now been inserted to fill up the places where the hairs came out; as if I were stung by a million bees at once; as if every drop of blood left in me had been suddenly transformed into an aching tooth — then as if all these teeth were drawn simultaneously, and the hollows filled with melted gold; as if I had been turned inside out, as Munchausen served the wolf, and then flung on a hot sand-heap; as if I had been flayed alive, and then set to wade up Vesuvius knee-deep in liquid lava, and in a shower of red-hot cinders, without boots on, and with no umbrella; as if all my nails had been dragged off with blacksmith's pincers, and my finger-tips dipped in liquid sealing-wax; as if — Well, if you have ever enjoyed the luxury of having a dentist file a tooth with "a nerve exposed," and if you will imagine that delightful sensation multiplied by twenty-two thousand and eleven, and then complicated with neuralgia, tic douloureux, and cramps in the stomach, you may be able to get the ghost of a shadow of a faint approach to a remote comprehension of what I suffered in this one agonizing instant.

I again say "instant," for, though it leaves each fleshly particle of my body quivering with a sensation near akin to that feeling commonly known as having the "teeth set on an edge," the intense acuteness of the pain lasts but an instant — no mortal could endure it longer and remain conscious; in fact, fleeting as it is, I am only saved from a second faint by another timely dash of ice-water.

And what has happened is only one of those "exceptions" of which the doctor is about to speak, when the glass of water becomes necessary. *The scalpel has severed a nerve.* Though this exquisitely sensitive fibrilla, or remote offshoot of the brain itself, is probably not larger than a slender silken thread, the comparisons above written can convey but feebly an idea of the sickening pain occasioned by the cutting of the nerve-fibre. — *Mortimer Thomson, in Hours at Home for December.*

PHYSICAL CULTURE. — Perhaps I should say something here of that other physical culture which has become a mania in the Northern States; of those wonderful base-ball players who break their fingers and sprain their ankles; of college-boys who "train down" for boat-races, get heart disease by hard tugging at the oar, and die innocently young with startling suddenness; of "walkists" who esteem a leg as better than a locomotive; and of fancy navigators *qui trans mare currunt* in small boats, and get drowned. But all these are violations of what is the pivotal idea of whatever of value there may be in this article — COMFORT. Athletism is not the end and aim. It is only the means to a high Christian culture — the development of the sound mind in its necessary congener, the sound body. When we see a pack of school-boys in their wild play, exercising in the gymnasium, roaming fields and woods, or subjected to military drill, we can understand it. All they do lies in the channel of enjoyment, of amusement, happiness, and gratification of an honest pride. It is *comfort*, and that within proper bounds: not the false enjoyment which attends a debauch and is atoned for by a headache; not the pride which glories over a victory won by boat or ball at the cost of mutilated limbs or overstrained hearts. Good health, sound mind, pure hearts, true religion — these are the essentials of comfort. — *Dr. S. B. Hunt in Hours at Home for December.*

TO KEEP PURE AIR IN A SICK ROOM. — To avoid the foul gas produced by burning a kerosene lamp in a sick room or nursery, put the lamp in a wooden box (a raisin box will do) outside the window, with the open side of the box facing the room. The box can be fastened in its place in any convenient way. In ordinary weather the lamp will burn full as well outside, and the air in the room will be much purer.

A NEW STYPTIC COLLODION. — M. Carlo Paresi gives, in the *Gazette de Turin*, the following recipe: — Collodion, 100 parts; carbolic acid, 10 parts; tannin, 5 parts; benzoic acid, 3 parts. Agitate until a perfect solution is formed. It is of a brownish color, gives a pellicle similar to ordinary collodion, and instantly coagulates blood.

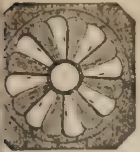
CINCHO-QUININE. — The large number of letters we are receiving by every mail from physicians residing in all parts of the United States, affords additional and strong corroborative evidence that we were not mistaken in our estimate of the value of a combination of all the bark alkaloids, in febrile and atonic diseases. Extracts from a few of these letters were given in our last number. It has long been known to a few physicians, that a mixture of the two sulphates, the sulphate of quinine and cinchona, supplied a more prompt and effective febrifuge and anti-periodic than either of the used singly; and now it must be generally admitted th the other alkaloids in combination diminish the un pleasant and increase the good effects of the drug. W do not expect that the cincho-quinine will prove equall satisfactory in every case, or that in every instance disease it will prove better than, or even equal to, su phate of quinine. It would be absurd to expect this. Bu that it is a very useful, and excellent, and cheap toni and febrifuge, cannot admit of a doubt. Its cost much less than sulphate of quinine, which is an im portant consideration.

VERMILION. — It is a fact, well known to artists, tha the splendidly bright color of vermilion (sulphide of mer cury) has a tendency, especially if it has been mixe with white lead, to become blackish brown and ver dark colored in a comparatively short time. This ten dency of the vermilion is altogether obviated if, previou to being mixed with oil, it is thoroughly mingled wit about one-eighth of its weight of flour of sulphur.

MEDICATED VAPORS. — Experiments are now in pro gress at the Neckar Hospital (Paris), and also at th Asylum for Convalescents, at Vincennes (France), upon the application of the vapor of water which has been caused to pass over various non-volatile salts, carrying with it a portion of them, to the treatment of disease Concerning the Convalescent Asylum at Vincennes, th *Gazette des Hôpitaux* reports, upon the authority of M Dionis, that of forty thousand convalescents admitted there during the past ten years, but one hundred and fifty-one have died, or in the proportion of one to five hundred and twenty-six.

TO GET RID OF COCKROACHES. — Under this head a Canadian paper gives the following, which would proba bly be improved for practical purposes by the substitu tion of *carbolic* acid for carbonic: — The *N. Y. Evening Post* says "take carbonic acid and powdered camphor, in equal parts, put them in a bottle, when they will become fluid. With a small paint-brush put the mixture on the cracks in places where the 'critters' hide, and they will come out at once, to certain death."

GARRATT'S



Electric Disk.

FOR LOCAL RHEUMATISM, WEAKNESS, PAIN OR PALSY.

A neat, self-acting *electrique*, that is powerful, easy, and com-rtable; and as it acts without shock, it is perfectly safe in all ıses. It is *unique*, for it is simply *to be worn* on the body or ımb (as if a plaster) for the tonic effects of constant localized ectricity. Any one can apply it, and the most delicate can ear it with ease.

This highly electrical *disk* (of *magnesite-zinc alloy* and *silver*) ields a minute but *constant primary current*, that can pene-ate the weakened underlying nerves and muscles, or deeper ated organs and tissues, so as to impart strength and tone, et is felt only as a pleasant, lively warmth. It is in effect ery efficient.

P. S. *For sale* by many prominent *druggists* and surgical strument makers throughout the United States and in Eng-nd. Price $3. Dealers will find these *disks* a very clean and ıperior article, compact, neatly put up in envelopes with rections, no way liable to break or injury, and keep perfectly ı the sea or in any climate. No losses, for they have ready le as a most convenient *special remedy* for a lame back, oulder, stomach, or side; for a weak throat or thorax; for *ld rheumatism*, neuralgia, or local palsy. The trade and edical men in the country supplied in quantities (*half-dozen, ozen* or *gross* boxes) at manufacturer's regular prices, by

ARTIFICIAL LIMBS.

ffice and Manufactory, 81 Green St., Boston, Mass.

PALMER'S PATENT ARTIFICIAL LEG,

AND

LINCOLN'S PATENT ARTIFICIAL ARM.

Also, Substitutes and Appliances for Shortened, Defective and eformed Limbs and everything sought for in a first-class estab-shment of this kind, constructed and applied by the most ilful operators, and fully WARRANTED.

The great reputation of these Artificial Limbs, and the well ıown character of this establishment, for the skill of its opera-rs, and for the completeness and perfection of its work, gained almost a quarter of a century of successful practice, will in-re the best results of human ingenuity and skill to such as ay apply here for relief.

Especially commissioned by the Surgeon-General U. S. Army supply as above to all Officers and Soldiers disabled during e late War. For further information address,

CODMAN & SHURTLEFF'S

Apparatus for Local Anæsthesia and Atomization of Liquids.

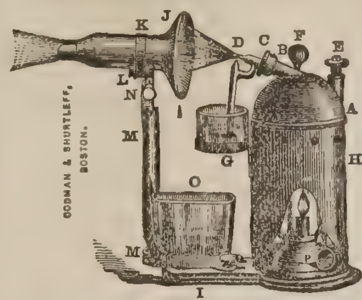

Fig. 15. The Complete Steam Atomizer. Pat. Mar. 24, 1868, and Mar. 16, 1869.

It consists of the sphere-shaped brass boiler A, steam outlet tube B, with packing box C formed to receive rubber packing through which the atomizing tube D passes, steam tight, and by means of which tubes of various sizes may be tightly held against any force of steam, by screwing down its cover while the packing is warm; the safety valve E, capable of graduation for high or low pressure by the spring or screw in its top, the non-conducting handle F, by which the boiler may be lifted while hot, the medicament cup and cup-holder G, the support H, iron base I I, the glass face-shield J, with oval mouth-piece connected by the elastic band K with the cradle L, whose slotted staff passes into a slot in the shield-stand M M, where it may be fixed at any height or angle required by the milled screw N.

The waste-cup, medicament-cup, and lamp are held in their places in such a manner that they cannot fall out when the apparatus is carried or used over a bed or otherwise.

All its joints are hard soldered.

It cannot be injured by exhaustion of water, or any attainable pressure of steam.

It does not throw spirts of hot water, to frighten or scald the patient.

Is compact and portable, occupies space of one-sixth cubic foot only, can be carried from place to place without removing the atomizing tubes or the water, can be unpacked and repacked without loss of time.

Will render the best of service for many years, and is cheap in the best sense of the word.

Price, $6. Neatly made, strong, Black Walnut Box, with convenient handle, additional $2.50.

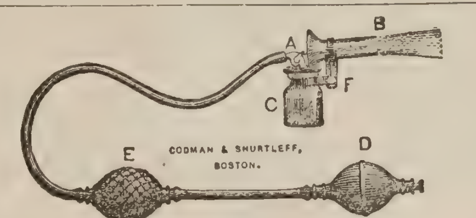

Fig. 5. Shurtleff's Atomizing Apparatus.
(Patented March 24, 1868.)

The most desirable Hand Apparatus.

Rubber warranted of very best quality. Valves of hard rubber, every one carefully fitted to its seat, and works perfectly in all positions.

The Bulbs are adapted to all the Tubes made by us for Local Anæsthesia in Surgical Operations, Teeth Extraction, and for Inhalation.

PRICE, $4.50.

Each of the above Apparatus is supplied with two carefully made annealed glass Atomizing Tubes, and accompanied with directions for use. The Steam Apparatus are tested with steam, at very high pressure. Each Apparatus is carefully packed for transportation, and warranted perfect.

ALSO,

HAND BALL APPARATUS (Fig. 5, without shield), with two Glass Tubes $4.00

SILVER-PLATED TUBES, for Local Anæsthesia and for Inhalation, each 2.00

RHIGOLENE, for Local Anæsthesia, best quality, packed 1.00

NASAL DOUCHE, for Treating Diseases of the Nasal Cavity, six different varieties, each with two Nozzles, packed . . . . $1.25, 1.50, 2.00, 2.50 and 3.50

N. B.—To save collection expenses, funds should be sent with the order, either in form of draft, post-office order, or registered letter.

[For complete Illustrated Price-List of Apparatus, Tubes, etc., see Pamphlet.]

Will be sent by mail (post-paid) on application, a Pamphlet containing two articles, by distinguished foreign authority, on

"INHALATION OF ATOMIZED LIQUIDS,"

With formulæ of those successfully employed.

Also an article by Dr. J. L. W. THUDICHUM, M.R.C.P., on

"A New Mode of Treating Diseases of the Nasal Cavity,"

WITH HIS FORMULÆ.

Also, an illustrated description of the *best apparatus* for the above purposes, and for producing Local Anæsthesia by Atomization with Ether, by the method of Dr. RICHARDSON, of London; or with Rhigolene, as described by Dr. HENRY J. BIGELOW in the *Boston Medical and Surgical Journal*, of April 19, 1866.

All our Atomizing Apparatus is made with the utmost care with a view to its complete efficiency, convenience, and durability, and every one is warranted. The Steam Apparatus (Fig. 1) has been adopted into the "Supply Table" as the standard for the United States Army. A Gold Medal has lately been awarded us by the Middlesex Mechanics' Association, for Atomizing and Surgical Instruments, as will be seen from the following report, signed by a leading New England Surgeon and Physician:

"1503. Codman & Shurtleff, Boston, Mass. One case Surgical Instruments and Atomizers.

"The Committee have no hesitation in awarding for this superb exhibition the highest premium. * * * * * The various other instruments for Inhalation of Atomized Liquids, and for Local Anæsthesia, were all apparently faultless, both in design and workmanship. The exhibitors are regarded as more especially deserving of the highest token of merit for having produced nothing except of their own manufacture.—**Gold Medal.**

"(Signed,) GILMAN KIMBALL, M.D., *Chairman*"

The following is an extract from a note from Dr. BIGELOW: "I have thus far found nothing better for freezing with Rhigolene than the tubes made by you after the pattern I gave you, and which I still use with your other apparatus."

Dr. J. MASON WARREN says: "Your apparatus for Atomization of Liquids seems to have been carefully made, and I think it an efficient one where required for treatment of diseases of the Throat and Lungs. The apparatus for Local Anæsthesia which you made for me answers the purpose perfectly"

ALSO FOR SALE,

Cammann's Stethoscopes, Disarticulating . .	$7.00 to $8.00
Simple Throat Mirrors	1.00 to 1.50
Ophthalmoscopes, Liebreich's	6.50 to 7.50
Holt's Dilator	18 00

Familiar Science.

THE STEREOSCOPE.

THE stereoscope is comparatively a new invention, dating back only some twenty years. A form of the instrument in which *mirrors* were used to produce the effect was devised by Wheatstone in 1838; but the stereoscope, as we are familiar with it, was invented by Sir David Brewster in 1849. The former is known as the *reflecting* stereoscope; and the latter, in which *lenses* take the place of Wheatstone's mirrors, is called the *refracting* or *lenticular* stereoscope.

We had taken it for granted that the philosophy of the stereoscope was generally understood, but a little inquiry among our friends—including some of the better informed among them—has satisfied us that this is not the case. Even some of our leading teachers know nothing about it. A few months ago, at a little gathering of gentlemen interested in physical science, the fact that the pictures formed in the two eyes are different was referred to by one of the company, together with the related fact that the two pictures of the stereograph differ in the very same way, when, much to the surprise of most persons present, both facts were squarely denied by a gentleman who had for many years been at the head of one of our best high schools, and for the greater part of the time a teacher of mathematics and physics. It was only after a long and rather lively discussion that he became convinced of his error. He had never before understood either the stereoscope, or the eye, so far as its action is like that of the stereoscope.

Why do we have two eyes, when we see but one image with them, and apparently one eye would serve to form that image? There may be other reasons for the arrangement, but the most obvious one is *that we may see objects solid*, or in relief, and not merely as pictures on a plane surface. It was not until Wheatstone made his experiments on binocular vision in 1838 that this matter came to be thoroughly understood even by scientific men. He showed that the pictures in the two eyes are not exactly alike, and that it is the blending of these two pictures which causes objects to appear solid.

A moment's reflection ought to satisfy the reader that the pictures in the two eyes cannot be exactly alike, since the eyes are not in precisely the same position with reference to the object. But if he "don't see it," a simple experiment will enable him to see it. Let him hold a book, or any other solid object, about a foot from the eyes, and look at it first with one eye and then with the other. He will find that with the right eye he sees a little more of the right side of the object, and with the left eye a little more of the left side. The same will be true, of course, whatever may be the distance of the object from the eye; though when the distance exceeds 250 or 300 feet the difference is too small to be appreciable, and objects beyond that distance are *not* really *seen* to be solid.

Now the stereoscope is simply a contrivance for blending two pictures which differ from each other as the images in the two eyes differ. When thus blended the pictures produce the same impression of solidity as the object itself does when viewed with both eyes. Hence the name of the instrument, which is from two Greek words, meaning *to see solid*.

How is this blending of the pictures effected? If we look at an object through the centre of a convex lens, it will be seen exactly in front of the eye; if we move the lens a little to the left, the object will appear to move to the right; if we move the lens to the right, the object appears to move to the left. If now we cut the lens into two semi-circular pieces, and place them side by side in a reversed position—that is, so that their thin or curved edges are adjacent, and their thick or straight edges are turned outward and parallel—the right eye will then look through the left half of the lens, and the left eye through the right half. If two pictures, like those of a stereograph, be placed at the proper distance behind the lens as thus divided and arranged, they will be seen, not in their actual places, but in a position midway between the two. The figure illustrates this: *m* and *n* are the halves of the lens; and A and B are the two pictures, which appear as one at C.

How are the two pictures obtained? They are photographs of the object taken from slightly different points of view. Theoretically, they should be taken from points separated by a distance equal to that between the two eyes, or about two and a half inches; and for all objects within short distances, this is just what is done. For objects farther off—as large buildings, or landscapes of considerable extent—photographers usually take the pictures from points farther apart; the distance ranging from a few feet up to a quarter of a mile. In this way, objects which are so distant that they are not really seen as solid with the unaided eye, are brought out into clear relief by the stereoscope. Even the moon may be made to show her rotundity of figure by means of this instrument. Although she always turns the same side towards the earth, she swings a little at times so that we get a view of a little more of her eastern or western side; and by taking advantage of this swinging (or *libration*, as the astronomers call it), photographs can be taken corresponding to the images in the two eyes—or rather, as Sir John Herschel has remarked, "it is as though the moon were seen with the eyes of a giant, placed thousands of miles apart." It has been suggested that similar photographs might be taken of the planet Saturn, with his system of rings. In this case, an interval of two or three years would be allowed between the times

of taking the pictures, in order that the position of the rings might change enough to answer the purpose.

A curious effect may be produced by tinting the pictures of a stereograph with different transparent colors. If, for example, one be colored blue and the other red, their blended image will appear purple; if blue and yellow be used, it will appear green; and so on. The colors are mixed *in the eye*, and the resultant color is precisely the same as if they had been mixed by a painter and applied to the picture outside the eye. We have seen French stereographs of statuary which illustrate this principle. One of the pictures is colored green and the other yellow, and the mixture of the two in the eye produces the exact tint of bronze.

Quite an amusing story is told of the first introduction of the stereoscope to the *savants* of France. The Abbé Moigno took the instrument to Arago, and tried to interest him in it; but Arago unluckily had a defect of vision which made him see double, so that, on looking into the stereoscope, he saw only a medley of four pictures. The Abbé then went to Savart, but he was quite as incapable of appreciating the thing, for he had but one eye. Becquerel was next visited, but he was nearly blind, and consequently cared little for the new optical toy. The Abbé, not discouraged, called next upon Pouillet, of the Conservatoire des Arts et Métiers. He was a good deal interested in the description of the apparatus, but unfortunately he squinted, and therefore could see nothing in it but a blurred mixture of images. Lastly Biot was tried, but Biot was an earnest advocate of the corpuscular theory of light, and until he could be assured that the new contrivance did not contradict that theory, he *would* not see anything in it. Under the circumstances, the wonder is that the stereoscope ever got fairly into France; but if you have any doubts on that point, a short walk under the arcades of the Rue de Rivoli, in Paris, will soon settle them. We question whether you will see anywhere else on earth more stereoscopes and stereographs than are displayed in the windows of the picture-shops of that noted thoroughfare.

HOUSEHOLD WARMTH.

In some observations regarding the evaporation of water in connection with stoves and furnaces, made in the Journal for December, it was stated that by heating air its capacity for holding moisture was increased; and the question is asked, if, in consequence of this elevation of temperature, it will not abstract moisture from our bodies, and thus rob us of that which is essential to health and comfort? This is a question very natural to arise in the mind of every one who reflects upon the important subject, and therefore we will give it a brief consideration. Undoubtedly warm air seeks moisture from all substances capable of supplying it. Air at a temperature of 65° F. is comparatively slow to abstract moisture; but, if it is heated beyond that point, its greediness increases at a rapid rate. The human body, as affected by warm air, is not like the walls of a room, and other substances with which it is brought in contact. It does not relinquish its aqueous constituents under the same laws; and we must regard it as a wise provision of Providence that the human organization is capable of resisting, to a very great extent, the influence of moisture-abstracting agents. We can live and enjoy the highest health in air so warm and dry that articles of furniture and books will warp and crack, greatly to their injury. These inanimate substances are forced, in obedience to general laws, to part with all of their contained moisture, when immersed in highly heated air. It has been said that the human body, physically considered, is made up of about a half dozen buckets of water, thickened with a few pounds of solid material. This is certainly a most homely way of stating a general truth. A man of ordinary size exhales or throws off from skin and lungs every day nearly a quart of water. Six adult occupants of a room will, during each hour, supply to the air nearly one half pint of water in the form of invisible vapor. This amount can be largely increased, under ordinary conditions, by elevating the temperature to a high point, and the increase will be mainly through the perspiratory functions. The stimulation of the functions of the skin so as to cause perspiration produces no sensation of *dryness*; excessive heat from furnaces seldom produces much perspiration. The peculiar air of a furnace, raised to a high temperature, affects the system through the nerves, rather than by stimulating the excretory organs. Neither warm dry air, nor cold dry air, robs the body of moisture, as they do fabrics of wood, cotton, or wool. The cold zero air of December contains scarcely a single grain of moisture to the cubic foot, and yet it is conducive to the highest health. A moist cotton garment will dry in it much quicker than in the hot air of a summer's day. It is evident we must seek some other explanation of the peculiar dry feeling of furnace heat, than that which attributes it to the abstraction of moisture from our bodies. The evaporation of large quantities of water in and upon furnaces and stoves affords after all but little, if any, real amelioration of our condition. The imagination has much to do with the supposed relief. A heated moisture-impregnated atmosphere is in no respect a comfortable one in which to reside. Do we not all dread the "dog days" of August, when the heat and moisture come upon us simultaneously? A dry air, whether it be cold and condensed, or warm and expanded, is, we are confident, more conducive to health, and better suited to the comfort or relief of invalids, unless in some special cases, than moist hot air. In the past three or four years we have advised invalids to remove water vessels from their stoves and furnaces, and give more attention to regulating the temperature of their rooms; and by following this advice, most striking benefits have resulted in every case. We wish distinctly to be understood as not attributing all the evil effects of anthracite stoves and furnaces to fitful temperatures, or to constant undue heat. There are other causes operating of a very serious nature, and these we will consider at a future time. We have now in hand a series of experiments in connection with furnaces, steam apparatus, &c., which will cover the whole ground of the comparative healthfulness of the various modes of securing household warmth, and we hope to be able to point out the real cause of the ill effects of anthracite coal fires upon the human organization.

PETRIFACTION.

A correspondent in the Onondaga Valley, where the "stone giant" has made such a sensation of late, writes to inquire whether earthy substances, as alumina, silex, etc., "will so combine with flesh as to become of stony hardness, or a petrifaction."

Every one who has read even an elementary manual of geology knows that the remains of plants and animals are found in the crust of the earth more or less *petrified*, or converted into stony matter. They are commonly known as *fossils*, a term which etymologically means nothing more than *dug up*. To the men of old time, and even to the earlier geologists, their occurrence was a riddle, and few considered them as other than mere accidents or *lusus naturæ;* but to the geologist of our day they are pictures in the great stone-book of the earth's history, illustrating the life that peopled the lands and the waters in pre-Adamite epochs, and indirectly the geographical conditions under which they flourished and became extinct.

A distinction is sometimes made between *fossils* and *sub-fossils*, as they are called. The latter are usually of more recent origin, and are only partially altered in texture; the former, as a rule, date back to earlier epochs, and the conversion into stone is complete. In the one case, the more volatile substances have been driven off from the plant, and the softer and more perishable tissues have disappeared from the animal, while mineral ingredients have been absorbed, to a greater or less extent, in place of the organic matter lost. In the other case, the vegetable, if not converted into coal, has been thoroughly changed by a slow process into stone, merely retaining its original organic form; and animal remains have undergone a similar metamorphosis, and are recognizable only through their forms and textures, which are unaltered.

What is the nature of this marvellous transformation from the organic to the inorganic state? It is not the result of a *combination* or *chemical union* of earthy matter with the organic matter, as the question of our correspondent implies, but rather a gradual *replacement* of the latter by the former. Particle by particle the organic matter disappears, and particle by particle the mineral matter takes its place; and so delicately is the substitution effected that scarcely a cell or a fibre is ever broken or displaced! The nature of the petrifaction will depend, not so much upon the composition of the plant or animal (though this will have its bearing on the result), as upon that of the mineral solutions which percolate the earth, the fossil being calcareous, silicious, ferruginous, and the like, according as the water contains lime, flint, or iron. In all cases, the process seems to be essentially the same; a gradual decay and dissipation of the organic atoms, and a gradual substitution, through permeation, of the mineral or inorganic.

In many cases the fossil itself is petrified anew, so to speak; that is, the mineral matter which was at first deposited is gradually dissolved out, and a new substance takes its place; or no new matter may be substituted, and merely the hollow mould may be left to prove that the organism was once there. Thus a shell or a coral, which consists of organized carbonate of lime, may be converted into the sparry mineral carbonate; and this may be dissolved and washed away, leaving a hollow mould marked with every ridge and line of the vanished organism; or this mould may be filled up again with silicious matter, so that the shell or coral seems to have been transmuted into flint, without losing the most delicate line traced on its original surface. The perfection with which the finest lineaments are thus preserved, after every particle of matter in the fossil has been twice changed, is almost incredible. As a writer on the subject remarks: "We have seen the faceted eyes of trilobites as perfect in form as when they received the rays of light through Silurian waters; carboniferous univalves with their color-bands still unobliterated; internal casts of *productæ* with their muscular apparatus displayed in a style of legibility to which no anatomical preparation could approach; and ink-bags of cuttle fishes so little changed as to furnish the pigments for their own portraiture."

Of course, all plants and animals are not preserved alike, nor are the same organisms always found in the

same state of preservation. Those that have partially decayed in the air before being imbedded in the earth will be less perfect than those that were buried by some sudden convulsion before decay had begun. The harder parts of plants, as roots, stems, and nuts, are more likely to be preserved than the soft and succulent portions. The shells, bones, teeth, and scales of animals will be found when all the fleshy parts have perished; and the larger and harder bones of a skeleton may be the only ones that escape destruction.

But the general nature of this process of petrifaction was all that we intended to discuss at this time. The subject is an interesting one in many of its details, and we may take it up again hereafter.

BATHING CHILDREN.

ORDINARY BATH.

Take some water, neither too warm nor too cold; pour it into a wooden tub or a large earthen vessel, such as a hand-basin; which should be of about the same temperature as the intended water. It is better not to use a metallic vessel unless it is a regular bath-tub. The water should *never* be so cold as to make the child *shiver* when put into it; and be very careful not to let the child strike the cold edge of the vessel, which is apt to frighten it and give future trouble when you attempt to bathe it at another time. See that the doors and windows are closed to keep little currents of air out of the room, which are apt to give it cold. The soap, towels and clean clothing for dressing the child again, should be got in complete order, and placed conveniently for use. Remove the child's clothing as you would at night, and be careful not to alarm it by anything you do. Place it sitting in the water, and then gently and rapidly wash the entire body, using some soap. The length of time the child should remain in the water must be left to the judgment of the mother; but in *no case* should it be continued until its lips and fingers become blue, or its teeth begin to chatter. Take it quietly out, and with a soft, dry, or even warmed towel, begin at the face and gently dry the entire surface of the body. Do not *scour* the skin with a single fold of the towel, but have it doubled. If you wish you may use a coarser towel afterwards. Dress the child as soon as possible, and be careful not to move it about the room too much before it is clothed, as you must remember a person moving about undressed becomes chilled much sooner than one who is kept quiet.

In the hot weather of summer, such a bath may be given once every day, unless there is some good reason for not doing so.

When a *bath* is ordered, a bath of *water* with soap is always meant, and in no case should mustard or anything else be used, unless you are told to do so.

SALT BATH.

This is given like the one just described, only you add as much common salt to the water as may be necessary. It is well to remember, that "salt cools water," as the saying is; so you must have the water rather warmer before the salt goes in than you wish the bath to be after the salt dissolves.

For the purpose of bathing, it will be found that the ordinary coarse salt is quite as good as what is called "rock salt."

HOT BATH.

This bath is not often necessary for infants or children, and when given, it should be by the advice of some competent person. Physicians frequently order it in certain affections of the chest, which usually occur in the cold weather; and, when ordered, do it as follows, unless a different plan is told you:—

Take an ordinary hand-basin, or, if it is not large enough, use a small, wooden tub, and stand it in front of a fire until the inside becomes quite warm. Then pour into it the water, which should be as hot as the child can bear without inconvenience. The skin of an infant is much more sensitive to heat and cold than a grown person's hand; so it is well not to forget that what may appear quite warm to you, will prove too hot to the child. As in the "Ordinary Bath," just described, see that every door and window has been closed, and let no one come into the room until the child has been bathed and dressed. The clothing should be carefully removed, and, while doing this, do not let the child become frightened, as it often will at your preparations. Then stand it in the tub, and, with a towel which has been dipped into the water of the tub, wash its limbs and the lower part of the body. The child should now be made to sit down in the water; then with the towel, wash the other parts of the body, neck, and face which are not under the water. Do it quickly, but *never* forget to be gentle. A little castile soap may be also used.

The length of time which the child should remain in the bath, must, as in other cases, be left a great deal to the intelligence of the mother; but usually it should not exceed two minutes. A good general rule, in the absence of a better one, is, to take it out as soon as the perspiration breaks out on the skin. Where the skin is wet this is hard to tell; but if you will look at the forehead, close to the hair little beads of moisture can be seen coming out on the reddened skin.

The child has now had the bath; but the more important things are yet to be done. The first of these is to have an old soft towel, which has been made quite warm at the fire; then begin to dry the face, neck, shoulders and downwards as far as you can. After this, lift the child from the tub and finish the gentle but rapid use of the towel. The clothing which is to be next put on should have been all arranged for use before the child's garments were taken off for the bath; and the linen, flannel, and whatever else is to be put on, all nicely warmed before the fire. Lastly, have a small blanket (the one used for the cradle will do), and after it has been warmed, wrap it around the child, secure it at the neck with a pin and the little one is ready for the bed. If all of these things have been done, and in this way the child feels quite comfortable, it would be a pity to put it into a cold bed; so, while you are dressing it, let some one take a hot iron, and with it go over the place in the bed where the child is to lie.

Arts.

CHEMISTRY OF THE EXPOSITION OF '67.

(Concluded.)

ARTICLES USED IN DYEING AND BLEACHING.

Aluminate of soda is obtained from cryolite in the manner already described. A better source is a mineral called beauxite, which contains sixty to seventy-five per cent of alumina. Aluminate of soda is used as a mordant, being preferred to alum in certain cases and for preparing alumina. A current of carbonic acid gas, passed through a concentrated solution of aluminate of soda, throws down all its alumina as a dense powder. From this precipitate are easily prepared the sulphate and acetate of alumina. The sulphate is a salt of considerable importance, for it can be sold cheaper and is purer than alum, and contains more alumina, weight for weight. It has also the great advantage of being entirely free from excess of acids, and therefore, for these reasons, will largely take the place of alum. To prepare the sulphate, the alumina precipitated by carbonic acid is simply dissolved in a little less than the equivalent quantity of sulphuric acid; but to make the acetate, the alumina must be thrown down by hydrochloric acid, else it will retain some carbonate of soda, which lessens its solubility in acetic acid. Where alum is used, the ammonia salt is often employed instead of the potash from its greater cheapness.

The use of bisulphite of soda for bleaching wool and vegetable fibres, is increasing. It produces a silky whiteness, that the hypochlorites will not give. The uses of hyposulphite of soda (as an antichlore) are also extending.

Dr. Smith gives details of several proposed methods for making chlorine, some of which may hereafter be of value, if the price of oxide of manganese should be enhanced, but at present they do not supersede the latter. He has no improvement to chronicle in connection with the manufacture of that important bleaching agent, chloride of lime or bleaching powder. The residue, after making chloride of lime, contains chloride of manganese and some free hydrochloric acid. This residue is utilized in various ways. By one process, peroxide of manganese is recovered from it, but it is rather an expensive operation, and, while the native oxide is so cheap, will hardly find general application. By another, it is made to assist in the recovery of sulphur from soda waste.

Another bleaching agent which is destined to be of great value to bleachers, if what is claimed for it is true, is permanganate of soda. Green manganate of soda, mixed with a certain amount of sulphate of magnesia, when treated with water, dissolves to a red solution,—the permanganate. The substance to be bleached is placed in this liquid for a short time, and taken out with binoxide of manganese precipitated upon it. This is removed by a weak solution of sulphurous acid. One or two repetitions of this operation are said to produce perfect bleaching. This, it will be at once seen, is a very expeditious process. Where it has been practically tested, it seems to work with great success. In order that it should succeed, it is necessary that manganate of soda should be cheaply made. This is done by a method to be mentioned further on.

COAL GAS AND UTILIZATION OF THE WASTE PRODUCTS OF ITS MANUFACTURE.

The exhibition of retorts and furnaces was very complete. Excellent clay retorts from both France and Germany were shown. The Reporter especially praises the establishment and productions of this kind of the Paris Gas Co. For heating the retorts, Siemens's furnaces have been advantageously used. Distributing pipes of many kinds were exhibited. A Paris firm displayed some bitumenized iron pipes. These pipes are no recent novelty, but within a few years their use has been greatly extended for carrying water as well as gas. There are, however, many objections to pipes of this description, and it is unlikely that they will replace the ordinary kinds for gas distribution.

In the way of meters, there does not seem to be any thing new or of especial importance. Wet meters are in general use on the Continent, and therefore particular attention is paid to their manufacture. In England, the makers of wet and dry meters are engaged in active rivalry. In this country, we believe that dry meters are considered the best, and are supplanting the wet altogether. In regard to regulators and burners, there does not appear to be anything of importance to private consumers.

The utilization of the waste products of the manufacture of illuminating gas from coal has become very complete. The value of coke is well known, and it is easily disposed of. The aqueous portion of the condensible vapors contains in solution various salts of ammonia. Treatment with acids, lime, and distillation, are different methods of obtaining the ammonia in salable form.

The tar is a very complex liquid, varying in quantity and composition with the quality of coal used and the temperature of the retort. It is divided into different substances by distillation, each having its special value and use. The more volatile portions are the crude naphtha and the light oil. These are mixtures of hydrocarbons, and are separated by fractional distillation into liquids of various densities, of use for many and various purposes, such as the production of benzol and toluol, from which are made the aniline colors, for varnishes, for solvents, for scouring, for burning, &c. &c. From light oil, too, is obtained carbolic acid, which has become a product of considerable importance. Its applications are very numerous, and its manufacture has very largely increased in late years.

The principal application of the creosote or dead oil is to the preservation of wood, particularly railroad sleepers. It has also some use as a fuel and as a lubricant. The pitch is applied to all sorts of uses, such as making patent fuel, artificial asphalts, &c. Besides the hydrocarbons that are now specially separated, great numbers of others exist in coal-tar, which are not well understood, but when better known will be found to have their particular value. After the removal of its condensible constituents, coal gas is further purified by passing it over or through various absorbents, usually lime, oxide of iron, and acids. The most important impurity

to be got rid of, is sulphuretted hydrogen. This is taken up by lime, either wet or dry, but the spent lime is a great nuisance. The spent lime of the wet purifiers is valueless, but dry lime can, by weathering, become of some use as a fertilizer.

Fresh hydrated sesquioxide of iron absorbs sulphuretted hydrogen readily. It is used mixed with sawdust, in order to present a large surface to the action of the gas. On exposure to the air, the sulphide of iron takes up oxygen with re-formation of the oxide of iron and separation of sulphur. The material thus revived can be again used to purify gas, and thus alternated, until it becomes too much charged with sulphur, when it is burned, for the production of sulphuric acid.

At some establishments the last traces of ammonia are removed from the gas by acids. Dr. Smith gives quite a detailed description of the principal aniline colors, and the modes of making them, mostly taken from Dr. Hofmann's report, but even the shortest summary of it would be much too long for our columns, and, besides, the subject has often been treated in them.

MISCELLANEOUS. PRODUCTION OF AMMONIA, BARYTA, MAGNESIA, OXYGEN, PHOSPHORUS, BROMINE AND IODINE.

Ammonia and its salts are entirely obtained from the ammoniacal gas-liquor. For many purposes they are taking the place of potash compounds. Dr. Smith has nothing new to say concerning their manufacture, but he figures a simple and very convenient apparatus for the distillation of ammonia. Compounds of baryta are coming into some use. The sulphate is made for use in painting, under the name of *permanent white*, but it does not mix well with oil, and has not sufficient body, so it has to be mixed with white lead. We fear, however, that sulphate of baryta is better known as the substance used by some unscrupulous manufacturers to adulterate white lead.

The only new application of magnesia is Sorel's use of oxychloride of magnesium. A mixture of chloride of magnesium with magnesia, like the oxychloride of zinc previously made by Sorel, solidifies in a very short time, forming a hard, smooth, close-grained, white, slightly translucent, stony mass. When new mixed, it can be moulded like plaster of Paris. This mixture can be used to cement together sand and other materials to make building materials, which, it is claimed, can be made very cheaply. In the last Mechanics' Fair, we noticed houses, emery wheels, building blocks and other articles made by a process of a similar character.

The exhibitor informed us that his company owned Sorel's patents for this country, but he claimed that they had made certain improvements upon them. Their articles appeared very well, but how they will bear the test of actual use, time only will show.

It is obvious that if oxygen can be cheaply made in large quantities, it can be put to very many useful applications. Many processes have been proposed to accomplish this most desirable object, but none of them promise to be of much importance, except Tessié du Motay's method by the use of the alkaline manganates.

This process has been fully described in our columns, and therefore we will only say here, that by it oxygen is obtained by passing alternating currents of air and steam over a heated mixture of oxide of manganese and soda. From the air-current oxygen is taken up, which is again yielded to the steam. This process is being tested on a large scale, and if successful, as it probably will be, cannot fail to be of very great value. We have already alluded to the use of the manganate of soda thus formed as a bleaching agent.

The production of phosphorus has largely increased, but there is nothing else worthy of notice connected with its manufacture. Amorphous phosphorus does not supersede the use of the ordinary form in friction matches. Many objections to it have yet to be overcome. The production and applications of bromine are increasing. Its latest use is in making some of the aniline colors. It is made from saline mother waters, but lately a new source has been found in the Stassfurt deposits, from whence large quantities are now obtained. The effect of this discovery will be to lower the price of bromine, which, of course, will have a tendency to extend its use. From the soda-nitre beds of Peru are now obtained considerable quantities of iodine. This locality will probably continue to furnish large amounts of this important article for years to come.

ARTIFICIAL ICE.—Ice has long been manufactured in parts of Europe, where the natural product is much more expensive than here; but it is only recently that the competition with "old Boreas" in this line of business has been attempted in the United States. Artificial ice is now made on a large scale in Philadelphia, and its cost is said to be only about half that of ordinary ice. The materials used are water, spirits of ammonia (commonly called hartshorn), steam, and salt. The retort is used for the heating of the ammonia. A coil of pipe, through which steam passes, winds around the interior. Eight hundred gallons of the ammonia are poured into the retort, and about twenty-four pounds of steam applied. The gas arising from the ammonia is conveyed into a pipe at the top of the retort. The pipe passes into a cooler filled with water, and thence into the liquefier. It now becomes a freezing cold liquid. Connected with the condenser is a pipe which carries this liquid into a series of pipes, which diverge through the freezing box. The latter is filled with a strong solution of salt and water, which, with the aid of the liquid ammonia in the pipes, causes an intense cold. Into the freezing box are introduced forty-eight brass boxes, filled with fresh water, each of them producing a 24-pound slab of ice, four inches in thickness, two feet in length, and one in breadth. It requires four hours to freeze the contents of the forty-eight boxes.

A DEEP WELL.

WE have received the following interesting note from Dr. H. Shidy, of the State Lunatic Asylum, Mo.:

"The article under this caption in the December number of your excellent JOURNAL contains several mistakes. St. Louis, Mo., has *two* of the deepest artesian wells in the world. One is at Belcher's Sugar Refinery, and, 'as long ago as 1854, this well had been bored to a depth of 2,199 feet,' where an abundant, self-discharging supply of water was obtained; but being strongly impregnated with sulphur and other impurities, which unfitted it for use in the refining of sugar, the work was abandoned, and has not since been resumed.

"The other well, the *deepest in the world*, was intended to supply the County Insane Asylum with water; and having reached a depth of 3,843 feet, six and one half inches, and penetrated some distance in the igneous rocks without obtaining water in any considerable quantities, boring ceased on the 9th day of August, 1869. The work had continued without interruption night and day for 1,235 consecutive days, or three years, four months, and twenty days."

GOLD AMONG THE BLUE NOSES.—The quantity of gold produced in Nova Scotia from the date of the first discovery of the precious metal to the end of 1868, a period of eight years, amounts to 160,000 ounces. The best year was 1867, when the yield amounted to nearly 30,000 ounces.

AMERICAN INVENTIONS ABROAD.

A BOSTON physician was in Paris the present year, and purchased there a microscope. He heard much of a new "oculaire" (*i. e.* eye-piece, as called by English and American opticians), lately invented by Hartnach, one of the most—and deservedly so—eminent of European microscope makers. Many American gentlemen had purchased this new "oculaire," and our friend also obtained one for his new microscope. His surprise was great, on showing his improved instrument, after his arrival home, when he was told that it was the solid eyepiece, which was invented and patented in 1856 by Robert B. Tolles, then of Canastota, but now of Boston, and was well known to, and extensively used by, American microscopists. C. S.

A CASE OF SPONTANEOUS COMBUSTION.

Editor Journal of Chemistry:

A merchant in this place received a box from Baltimore containing, among other things, ordinary bat cotton, and a can of Japan lacquer, or varnish. In transportation the can was broken, and the contents ran out, saturating one or two bats of the cotton. The box was received in the evening, and put in the store at night. When opened the next morning and exposed to the air, the cotton was found to be hot and smoking. The merchant took the precaution to lay it out at the door, when it ignited and blazed up. The cotton might have been taken out of the box the evening it was received, and carelessly laid aside, or it might have ignited before the box was opened; in either event the whole stock of goods would have been destroyed, and several houses in addition. The origin of the fire would, of course, have been attributed to an incendiary. The packing of Japan varnish with combustible articles, I suppose, is frequently done; and is it not well that the public should know the dangerous results that might ensue? I was ignorant of the fact myself, and I suppose others are also, as the box was put up by a reliable house engaged in the drug trade in Baltimore. There was nothing else in the box that could have had any agency in the combustion.

WM. H. BRAMBLITT, M.D.

Newbern, Va.

NEW KIND OF PAPER.—A new kind of paper, specially adapted for various kinds of clothing, has been invented in England. Both animal and vegetable materials are employed in its production, the latter being New Zealand flax, jute, hemp, and cotton, and the former wool, silk, skins, etc. These matters are reduced to a pulp and bleached, and then felted in appropriate machinery. The mixture of these materials gives a paper of extraordinary pliancy, flexibility, and strength, which may be sewn together as easily as woven fabrics, and make as strong a seam. Among the articles made of the paper are quilts and table-cloths, stamped with patterns of great beauty, curtains, shirts, and various other articles of dress; a very good imitation of leather is made of it, of which furniture coverings and even shoes may be made. The last may be rendered waterproof by the introduction of oils and India-rubber.

THE SANDWICH ISLANDS.—A few weeks ago we listened to a very interesting and instructive lecture upon the Sandwich Islands, given by Mr. George S. Chase, before the Y. M. C. Association, at Haverhill, Mass. Mr. Chase, who has charge of the publishing department of the JOURNAL, has been a very extensive traveller, having travelled around the world, and visited almost every country in both hemispheres. He writes with ease and fluency, and his narratives of personal observations and adventures are graphic and comprehensive. An evening can be very profitably and pleasantly spent in listening to his narratives of travels.

Agriculture.

A SCHOOL OF AGRICULTURE.

Since the publication in the Journal of some remarks regarding the Agricultural College at Amherst, a very considerable curiosity has been manifested by our readers, to learn what kind of an agricultural school or "college" we would suggest, as promotive of an intelligent and successful husbandry. When pressed for a reply to the question, in private, we have said that the *first* lesson we would teach farmers in "our college" would be, how to turn oil of vitrol out of a carboy, and not spoil the clothing; *second*, how properly to dissolve bones, prepare phosphatic fertilizers and efficient composts; *third*, how to use and how to take care of agricultural implements; *fourth*, how to lay drain tile; *fifth*, how to plow and pulverize land so as to fit it for seed; *sixth*, how to make and save manures; *seventh*, how to feed and properly take care of stock; *eighth*, how to keep buildings and fences in order; and, *ninth*, how to keep, systematically and accurately, farm accounts. Although this synopsis of a course of instruction in agriculture has been given partly in jest, still, upon consideration we are convinced that the points embrace about everything which modern science can teach farmers, or nearly all that is necessary to be known to attain the highest success in soil cultivation. While a knowledge of the higher branches of mathematics and of the natural and physical sciences is very gratifying and desirable, still the possession of such knowledge does not necessarily make good farmers. Indeed, we can conceive how in the acquirement of these branches of learning, a very promising boy-farmer may be spoiled for any good practical work in husbandry. Agriculture can hardly be called a science; it is an art, a vocation, which science can assist in perfecting, just as it does assist in facilitating all industrial pursuits. Agricultural labor is so modified and interfered with by meteorological and other uncontrollable influences, that it cannot be classed among those pursuits where fixed results may be expected from a definite course of procedure. While it is true that not a single movement in the progress of the growth of a plant can be made without involving chemical changes, chemistry is incapable of explaining the exact nature of these changes, and also it is incapable of pointing out methods by which certain and positive results may be reached. In our view, a good and sufficient agricultural education may be acquired without a four-years' college course of study, without the aid of extensive laboratories, museums, herbariums, or mineralogical cabinets. We believe what is needed for the interests of agriculture is not so much "agricultural colleges," where young men are to have prolonged training in such branches of study as are taught in our ordinary educational institutions, but schools to which active farmers and their boys may resort in the winter months, and learn by observation and experiment how practically to conduct farming operations to the best possible advantage.

Let us draw the outlines of such a school. In the first place, we would locate the school — or "college," if you prefer—upon a farm which has been under thorough, judicious, and enlightened cultivation, and which has the variety of soils, the uplands and the lowlands, the northern, southern, and other exposures, needed to show the influences of meteorological agencies upon crops. We would have the farm buildings plain but substantial, and combining every improvement of tested, practical value. There should be a herd of fine animals, embracing the different kinds of stock, with horses, sheep, pigs, and poultry. The arrangements for supplying water, foddering the animals, and saving the liquid and solid excrement, should be of the most inexpensive, but efficient character. The tie-ups, the stalls, the pens, the root cellar, the tool-room, the grain-bins, the food receptacles, should be most convenient, accessible, and kept in perfect order. A set of farm implements should be provided, embracing every kind which upon trial has proved to be labor-saving and useful. In brief, this is the farm.

Now another building is needed, which we will call "the College." This may be a plain, substantial structure, with dormitories, kitchen, and two or three lecture rooms. It should not be large, as it is not desirable to have a great number of "students" congregated together. It will probably be better to increase the number of "colleges," if needed, rather than have large institutions, as in this way they will be brought within easy distance of farmers' homes. There should be a very broad, cemented, well-lighted, and warmed basement, to be used as a "laboratory." Here we will place our carboys of acids, and our barrels of "salts and alkalies," to be used in compounding our fertilizers and making composts. As the time of greatest activity in the college will be in the winter, when farmers are comparatively at leisure, it will be well in the Northern States to provide a capacious cellar with a soft bottom, for the purpose of giving practical instruction upon the philosophy of land drainage, and the method of laying tile and stone drains. We need not particularize further as regards what will be required. The necessity of having a full assortment of all kinds of the best seeds, and perhaps dried plants, for examination and study, and also a moderate quantity of chemical "tools" and re-agents, to illustrate some of the most simple and easily understood chemical reactions, will be apparent.

Now as regards "term time," students, and methods of instruction, we propose to have school open in the winter months, to receive pupils direct from the farms of all ages and conditions. Of course, the very young and the very old would not wish to resort to it. One class of students — the active, busy farmers, whose duties will not allow of protracted absence from home — may "graduate" after *one or two weeks* of study. There should be a special course of instruction for such, eminently *practical* in its character, without long lectures or learned essays. The fertilizers and composts should be prepared under their eyes, drain tile laid, short discourses given upon stock, grains, plowing, saving manures, making manures, etc. Every suggestion and every facility for obtaining valuable information should be afforded, and also a free range given of all the departments of the school and farm buildings.

Another class — farmers' boys, who can attend school in the winter months—may be "graduated" in three, or perhaps four, months. The course of instruction in connection with this class should be plain, concise, useful, and have direct reference to the duties of the farm.

Still another class, who desire practical instruction upon the farm in the summer, may remain a year, not longer. The first class of farmers may take a second or third term of instruction of a week or two, if they desire to do so. Indeed, progressive farmers would probably like to spend a short time at the school each winter, to keep themselves informed of every thing new in agriculture; and to this there can be no objection.

The "Professors" in this school should be no *second* or *third rate* men, no quacks or pretenders. A thorough, practical, operative chemist, with a clear knowledge of farm pursuits and duties, would be required for the "chair" of chemistry. A man acquainted with fruit and vegetable culture, with the selection and preservation of seeds, &c., would be needed. A good, sensible, wide-awake farmer must have charge of the farm and farm buildings, and perhaps one or two assistants may be required in the institution.

This is a very rough and imperfect outline of a plan of an agricultural school, which we are confident would be of incalculable service to the interests of agriculture, if it were established. Its influence upon farm pursuits would be immediately seen, and an improved and more profitable husbandry result, whenever farmers could avail themselves of its advantages. The plan is economical of time and money, and it brings agricultural education home to the door of every earnest, industrious cultivator of the soil.

OATS CHANGING TO RYE.

Editor Boston Journal of Chemistry: —

I noticed in the October number of the Journal of Chemistry, that a correspondent has revived the long disputed question whether oats, sown in a pasture and fed down by animals during summer, will change to rye the following season.

The solution of this question involves the principle of transmutation of species. Professor Agassiz, when speaking of transmutation, says: "I nevertheless insist that this theory is opposed to the processes of nature as far as we have been able to comprehend them, and that it is contradicted by the facts of embryology and paleontology." Professor F. J. Pictet, the distinguished French naturalist and paleontologist, says: "The theory of transmutation of species appears to me entirely inadmissible, and diametrically opposed to all the teachings of zoölogy and physiology."

Now, there appears to be no doubt that oats and rye are distinct species. They are very different in form, and are ranked by botanists as belonging not only to different species, but also to different genera. They have never been known to hybridize, which is the surest proof of their specific difference. If, therefore, the opinions of these two great masters in science are correct, oats can never change to rye.

But, if we adopt Mr. Darwin's theory, that species are transmutable, the case under consideration will not fall within the circle of conditions which that theory requires. Mr. Darwin says: "New species have appeared very slowly, one after another, both on the land and in the waters." The change, therefore, by which one species is evolved from another, is the result of a long and gradual process by repeated reproduction in plants from the seeds, and could not take place in one season, as in the changing of the oats to rye. Many years, perhaps centuries, would be required to cause a divergence sufficient to produce a specific difference.

In the case of the oats, nothing has really been done to change the nature of the plant, except to cut off or bite off its leaves. It seems to me that it would be just as reasonable to suppose that cutting off the ears of a mule would change him to a horse, as that biting off the leaves of oats would change them to rye. But, so far as I have known, when the experiment has been made to test the truth of such a change, it has entirely failed. A careful examination of the process of the fertilization and the embryonic development of plants would, I think, convince any one of the utter absurdity of such a transformation. The cases adduced in proof have, no doubt, orig-

inated with superficial observers, and on thorough examination would be found to involve some latent fallacy adequate to account for the supposed transmutation. P.

Washington, D. C.

GIRDLING FRUIT TREES.

EVERYBODY has heard of the rascally act of certain miscreants in Michigan, who girdled fifteen hundred fruit trees belonging to a man against whom they had a grudge; and likewise how the neighbors turned out *en masse*, and bandaged the trees with cloth strips dipped in great kettles of heated sealing-wax. The outrage was repeated, and again the friendly surgery of the neighbors came to the aid of the mutilated trees, though, as was stated at the time, with small hope of saving them. The sequel of the history does not appear to have become so generally known. Strange to say, the trees all lived, and bore such fruitage as had never before been seen in that region. The marvel has made a great sensation in the vicinity, and the theory has been promulgated that fruit trees can be made to bear more abundantly by girdling them. This would seem to be rather a hasty generalization from the facts in the case, and we advise our orchardists not to try the experiment upon too many of their trees at once. Some have suggested that, though the interception of the sap in the girdled trees has caused fruit to grow instead of wood this season, the real trial of the trees will come next year. Time will show; and, as we have had occasion to tell farmers more than once, they must wait until time *does* show results that can be *depended upon*, before they are in haste to jump at conclusions. An experiment in farming is seldom worth a copper if it has not continued for *five years* at least. *Sequence* is very likely to be confounded with *consequence* (the *post hoc* with the *propter hoc*, as the logicians would say), if this rule is not borne in mind. It is a pity that writers on agriculture and teachers of agriculture so often forget it.

FLIES ON HORSES.—The following is given as a preventive of horses being teased by flies: Take two or three small handfuls of walnut leaves, upon which pour two or three quarts of cold water; let it infuse one night, and pour the whole next morning into a kettle and let it boil for a quarter of an hour. When cold it will be fit for use. No more is required than to moisten a sponge, and before the horse goes out of the stable, let those parts which are most irritable be smeared over with the liquor, viz.: between and upon the ears, the neck, the flanks, etc. Not only the gentleman or lady who rides out for pleasure, will derive pleasure from the walnut leaves thus prepared, but the coachman, the wagoner, and all others who use horses during the hot months.

THE RAIN-FALL OF AUSTRALIA.—The mischief done by clearing a country of its forests has in some cases undoubtedly been over-estimated, but man cannot always remodel nature with impunity. In Australia, since 1863, the rain-fall has gradually diminished from thirty-seven inches in that year, to seventeen inches in 1868. This year, the fall during the two wettest months has been unusually small. In the Colony of Victoria, the government has appointed an Inspector of Forests, whose duty is to prevent the destruction of forests, and to establish nurseries of young trees in favorable localities, with a view to replacing, to some extent, the wooded districts that have been cleared.

Boston Journal of Chemistry.

BOSTON, FEBRUARY 1, 1870.

THE "WATER" QUESTION.

THE *N. Y. Medical Gazette* (a journal, by the way, conducted with much spirit and ability) in commenting on the views presented in the JOURNAL regarding the evaporation of water upon stoves and in furnaces, remarks as follows:

"It may be news to the chemical gentleman in question, to learn that there are certain physiological phenomena connected with excessive or defective humidity of the atmosphere; that under the latter condition, owing to the affinity of air for moisture, the respiratory surfaces will be refrigerated and dried by unusual evaporation from them; and that the same process, to a less degree, affects the whole surface of the body. Now, granting that in a literal sense, none of the existing moisture is expelled from air by raising its temperature, an immense relative reduction of its humidity is thereby effected. Suppose, for instance, that the atmosphere of a room of two thousand cubic feet contents have its hygrometric capacity for moisture satisfied on a freezing morning. We build a good fire in a stove and warm this room to, say, 75° Fahrenheit; and in doing this we so reduce the *relative* amount of moisture, that at least a pound of water is required to bring the air to the same condition in which we found it. And what is more, the thirsty air will have this water in some way, and, if we do not supply it by evaporation from external sources, will, to use a vulgar but appropriate slang phrase, 'take it out of our hides.' For our own part, we prefer the former alternative."

"It may be news" to the gentlemen of the *Gazette* to learn that millions of the human family are living under conditions where the "respiratory surfaces" are constantly being "refrigerated" and "dried" by zero air. These people manage to maintain a very tolerable degree of health, much better, we venture to presume, than a majority of those who are steaming themselves over furnace evaporating pans in dwellings in cities. The cold air of high northern latitudes is *very dry*, and in passing into the respiratory organs it has its capacity for moisture increased by warmth. Does it rob the air cells of the lungs of moisture, to the injury of health? Experience and observation prove that it does not. Robust health attends upon those who live constantly in the dryest air. The dry air of Minnesota and New Mexico is resorted to by invalids for sanitary reasons.

Dr. Hayes informs us that he has lived for months in the Arctic regions, when the air of the ship's cabin was so dry as to cause the panels and mouldings to shrink until they almost fell from their places, and yet he suffered no inconvenience or injury to health.

The views expressed by the N. Y. medical gentleman are based upon the vulgar notion that the human organism and inanimate objects are alike influenced by dry air. The human body is a very complex piece of machinery, and its relations with external objects are very imperfectly understood. Enough, however, is known to prove that it cannot safely be compared with anything but itself, in all its physical and chemical changes. The experiment suggested by the *Gazette*, to be made upon a "freezing morning," should, theoretically, give the results indicated, yet practically it would not. The gentleman need entertain no fears of having "a pound of water taken from his hide," if he builds a rousing fire in his cold parlor some "freezing morning." If he will watch the indications of the wet and dry bulb thermometers, it will be seen that the supply of moisture very nearly keeps pace with the rise in temperature. Precisely how or where the thirsty air obtains its moisture so readily and rapidly, we do not know, but abundant proofs exist that but little of it comes from "our hides." It is possible that cold dry air suddenly warmed in our rooms has a power of absorbing moisture from the outer air through channels entirely unrecognized by us. The popular notions regarding the importance or necessity of throwing into our rooms large quantities of moisture from artificial sources, are due principally to inventors and makers of new patent stoves, new evaporating devices and "hygrodeiks," and have about as much scientific value as any of the taking newspaper advertisements. We are sorry to see first-class scientific journals following in the lead of these enterprising advertising philosophers.

THE RE-CAPITATED BRAZILIAN.

OUR readers have seen the story which has been going the rounds of the papers regarding a convict in Brazil, Aveiro by name, who was executed by decapitation in company with another prisoner, and who, having the other man's head placed upon his bleeding trunk by Dr. Lorenzo y Carino, a physician of Rio Janeiro, "recovered," and ran away with a head not his own. This story is defective in several particulars. To increase the interest and wonder, the head should have been placed upon Aveiro's neck *with the face to the back* instead of in its right position. Under the influence of Dr. Carino's "wonderful electricity," the wound would undoubtedly have healed just as readily, and the man would have "recovered" just the same. What an interesting "physiological experiment" this would have been! It is true that Aveiro would be put to some inconvenience by the novel position of the "face divine," but the "little stiffness" in the neck spoken of in the statement, which he experienced for some months, might possibly have been avoided. It would be a little awkward to have to turn the back to a friend to make a bow, and also, in walking backwards, there would be danger of tumbling over fences and into ditches. Notwithstanding these disadvantages to the individual, we are sorry for "science" that Dr. Carino did not stick on the head the other way. If Barnum could get hold of Aveiro, even as he is, and conjoin him with the Cardiff Giant in one grand exhibition, they would "draw" immensely. Of course the Brazil story is true, for it has not only been copied into the newspapers generally, but also, in all soberness, into many scientific journals of high pretensions.

VACCINATION.—The recent attempts made in England and to some extent in this country, to create popular prejudice against kine-pox vaccination, cannot but be deprecated by every well-wisher to the race. The writer or public speaker who in this epoch of time denounces and condemns the great discovery of Jenner, must be either a fool or a knave. If the utility of any principle or discovery has been fully and conclusively verified and established, it is that of Jenner, which stands as a guardian angel to shield us from a disease, the bare contemplation of which fills us with horror.

The outcry against vaccination is based on the plausible and taking theory, that dreadful diseases are communicated through the act of vaccination. In general, this theory is unqualifiedly false, and its promulgation is worthy only of quacks and charlatans. In the millions who have been brought under the protective influence of kine virus, not one per cent. probably have suffered extraneous injury in any form. The investigations and researches upon this point have been of the most

extensive and reliable character, and the testimony to the safety of kine-pox vaccination, when properly performed, is satisfactory and conclusive.

Let none of our readers be led into the serious error of imbibing prejudice against vaccination. As they value their own lives and those of their little ones, let them avail themselves of the "great protection." Commendable care is exercised by all respectable physicians in the selection of matter, and they are the proper persons to attend to the service.

A Case in Court. — The case of Mr. Wellington, a lawyer of this city, who was badly injured by a kerosene lamp explosion last spring, came up for trial a few weeks since in the Superior Court. Mr. Wellington, who resides on Temple St., purchased the spurious kerosene of one Chase, a dealer, on Cambridge St., who in turn purchased it of the Downer Kerosene Oil Co. Mr. W., instead of prosecuting Chase, went back of him, and claimed damages of the Downer Company. When the case came up for trial, Judge Lord ruled it out of court on the ground that no action would lie against parties not directly concerned in causing the damage. The direct agent was Chase, and Downer only the indirect agent. He could not be made to suffer, so long as he had nothing to do in the sale of the naphtha to Wellington. This is undoubtedly good and safe law, which will be sustained on appeal to the Supreme Court. Messrs. Downer claim that they sold the article to Chase as "naphtha spirits," and he sold it to Wellington as "burning fluid." It is earnestly to be desired that the villains who are making and retailing the death-dealing illuminating fluids, should be made to suffer. There is law enough, and it is evident that juries are ready and eager to convict, so soon as instances of fraud are properly brought before them. Let the people protect themselves.

Kind Words From Subscribers. — A farmer subscriber in Vineland, N. J., in sending for the back numbers of the Journal, remarks as follows: "The long evenings now afford me a good chance to read the back numbers of the ever-welcome Journal of Chemistry. I like your Journal very much, and I wish I had taken it from the beginning. I should like to procure and read all the numbers of the former volumes."

Another subscriber in Medina, Ohio, says: "I have taken the Journal one year, and it has given me the greatest satisfaction. Many a pleasant hour have I spent in perusing its interesting pages, and I am certain that any one number is worth more than you ask for a volume." Another says: "When your Journal was brought to my notice by a friend, and I was advised to subscribe for it, I said, What do I want of a journal of *chemistry?* I am a plain farmer, I can't understand it. But, thanks to my good fortune, I *did* subscribe for it, and now I find I *can* understand the Journal of Chemistry. It has been *worth its weight in gold to me.* Every number is read and re-read, by all the members of my family, and we wait for its monthly visits with much impatience." Still another says: "If the question came between giving up the little Chemical Journal and the half dozen other papers I take, I should let them all go, and hold on to the Journal."

Nearly every mail brings a dozen or more letters containing just such kind words of encouragement as is presented in the above extracts.

Coal-tar Paint. — Some months since allusion was made to the use of coal-tar paint in the Journal, and its application to shingled roofs, fences, &c. recommended. Since that item was published, we have been led to investigate the liquids which are largely used under the name of "coal-tar paint," and we regret to say that most of them are nothing more than crude coal-tar taken from gas-works and thinned with naphtha. This gross product holds ingredients positively injurious to woody fibre, causing in it speedy disintegration and decay; such are free ammonia, sulphur, and organic acids. The "paint" we intended to commend is prepared from asphaltum, the solid product of coal-tar distillation. This substance, when dissolved in naphtha or turpentine and mixed with oxide of iron, forms a very good and safe paint, but the filthy and deleterious coal-tar must never be used upon wood-work. As it is difficult for most of our readers to know regarding the nature of the coal-tar substances employed by painters and roofers, it will perhaps be the safer way to refuse to have any of the "paints" applied to buildings.

☞ That sterling publication, the *New York Medical Journal*, edited by Professor Dunster, and published by D. Appleton & Co., makes the following pleasant allusion to this Journal and its editor in the December number:—

A Commendable Example. — Dr. James R. Nichols, editor of the Boston Journal of Chemistry, — by the by, the most wide-awake journal of its class in the country, — gave a handsome entertainment to the Essex North Medical Society, at its recent fall meeting. During their entire visit to the doctor's farm, "Lakeside," it is said that not a "case" was mentioned, nor were pills, boluses, or powders, even alluded to. The whole affair was devoted to recreation, and we are sure no class stand more in need of it than our hard-worked profession.

To Delinquents. — We send bills in this number to a few delinquent subscribers, and we hope that not one of them will delay a moment in sending along the small sum of fifty cents, which is due. If one of these missives happens to be found folded in the Journal of any good, prompt, paid-up subscriber, let him regard it as a mistake. Do not upon any account sit down and write a scolding letter about it.

Velpeau. — The interesting sketch of the great French surgeon Velpeau, which we have published in the Journal, was written by Dr. F. Peyre Porcher, of Charleston, S. C., a gentleman of much culture, and who is known to many of our distinguished physicians.

☞ We recently made analysis of a specimen of whiskey sold by a town agent, which gave the following result:

Alcohol,	39 parts.
Sugar,	3 "
Burnt Treacle,	1 part.
Sulphuric Acid,	trace.
Water,	57 parts.

A very poor specimen of whiskey certainly, to be sold under State authority.

EDITORIAL NOTES.

Terrestrial Ups and Downs. — Land is going up, in other than a commercial sense, in some parts of our planet, and down in other parts. The islands of Jersey and Guernsey are slowly sinking, though they will keep above water for some generations yet. Meanwhile new islands are lifting themselves into view in the western hemisphere, and Chili and Sweden are likewise coming up. The earth hath its undulations, as the ocean hath, though the rise and fall of the terrestrial waves are more gradual.

Fossil Shells filled with Blue Vitriol. — An immense bed of fossil shells has lately been found in southeastern Russia. The shells are filled with beautifully crystallized sulphate of copper, from which it is proposed to extract the metal. This is a good illustration of what we have elsewhere said of the replacement of organic by inorganic matter in the process of petrifaction.

Liquid Fuel for Locomotives. — Naphtha has been tried as a fuel for locomotive engines, both in France and in Russia. A heavy train has been run at a speed of forty-six kilometres (almost twenty-nine miles) an hour, on an ascending grade, between Paris and Strasbourg, with a consumption of oil at the rate of from three and a half to five kilogrammes (about seven to eleven pounds) per kilometre. The experiments were under the direction of St. Claire Deville, and the results are considered very satisfactory; as was also the case with the trials of the same fuel in Russia.

Underground Dwellings in Africa. — Dr. Livingston, who was safe at last accounts, reports that he has found tribes in Africa living in subterranean villages. Some of their excavations extend for thirty miles, and have running rills in them. A whole tribe could stand quite a long siege in these singular abodes. Whether they have underground railways, as their African brethren in this country did in former days, is not stated.

The best way of Slaking Lime. — A French engineer has made an able report on the economy of using lime ground to a fine powder, instead of slaking it in lumps. He estimates the loss in using lumps at twenty-five per cent. Besides this saving of material, it is found that lime in powder is spread with greater facility, and the mortar thus made sets quicker, and is more solid.

The "Thunderer" a Blunderer. — The *London Times* copies in all soberness the story that the telegraph wires in New York were *melted* by the rapid succession of messages sent over them during the famous "gold excitement." The report was true, of course, and it is *likewise* a fact that the telegraph companies have determined that they will hereafter avoid the risk of melting their wires, either by sending messages too *fast*, or by transmitting any that are too *warm*. Ardent lovers are no longer to be allowed to communicate by telegraph, and messages which appear to be the expression of "hot haste" will not be taken on any terms.

A Prophet Without Honor. — The Peruvians have hanged Professor Falb in effigy, because he promised them an earthquake and a hurricane, which didn't "come to time." His prophecies seem to have frightened the people pretty thoroughly, large numbers having left their homes and fled to the mountains to escape the threatened visitation. We think they served him right, though we do not suppose that they would have liked it any better if his predictions had proved true.

A Formula for Scent Bags. — Take of coriander, orris root, and calamus aromaticus, four ounces each; of lavender flowers, eight ounces; of rhodium wood, one ounce; and of musk, twenty grains. Reduce to coarse powder, and bag it. The recipe is said by good authorities to be an excellent one.

Trade in Flowers for Perfumery. — A recent French authority states that to obtain one kilogramme of oil of roses, from 10,000 to 30,000 kilos. of rose petals are required; for the same amount of oil of lavender, 250 kilos. of the flowers; of oil of geranium, 2000 kilos. of the leaves; and so on. The trade in some of these perfumes is enormous; as may be inferred from the fact that the neighborhood of Nice alone produces annually $40,000 worth of a single flower, the sweet smelling Nizza violet.

The leaves of the orange tree are valued at about forty dollars a ton — in gold, of course.

A New Kind of Lamp.—At a meeting of the British Association for the Advancement of Science, not long ago, a lamp was exhibited which transmits light through living bodies. Small animals become as if transparent; and the thinner parts of the human body, especially in a child, are quite diaphanous. We have heard before of "letting daylight shine through a man," but it was not done in precisely this way.

Vagaries of the Type.—Printed matter is rarely immaculate in respect to typographical errors. It strikes us, however, that some of our medical journals are especially rich in these provoking little inaccuracies. The account of the lamp just mentioned, as given in a medical magazine, says that the "mogresium" light is best for the purpose. If that could not be obtained, it might be well to try *magnesium*. Sometimes these misprints are very pretty little enigmas. Thus, in a recent number of "Nature" (which, as a rule, is very accurately printed), we find the following in an interesting account of deep-sea dredgings by the British expedition of the last year: "I attifie leas 60haieddnts." From the connection it is probable that it means, "I have identified at least 60," but some readers might not see it.

De Profundis. — The deep-sea dredgings to which we have just referred, prove clearly, not only that animal life is abundant at abysmal depths, but also that light must penetrate to those nethermost parts of the ocean. The eyes of creatures found at depths of from 1,500 to 3,000 fathoms are in some cases more highly organized than those of many fishes. With such eyes colors can be readily distinguished; and, since many of the objects from these great depths are found to have varied and beautiful colors when brought up to the surface, it is reasonable to suppose that they are not destitute of color down there, and that they do not "blush unseen." The "unfathomed caves" of ocean are not necessarily "dark," as both poets and philosophers have heretofore pictured them.

Mental Progress of Animals. — It has long been assumed as an axion that *instinct* differs from *intellect* in being incapable of improvement; but a writer in "Nature" argues that it is no such fixed and unchangeable thing. He believes "that much of what has been termed *cunning* in animals will be found to be very much sharpened and made evident in quadrupeds and birds, owing to the new necessities imposed upon them by man the tamer, or man the destroyer." In support of this view, he urges the fact that "no bird or quadruped so high in the mental scale as the dog, horse, rat, rook, or sparrow, has been found in the lonely oceanic isles, or in any region free, or all but free, from human influence"; not because such animals could not exist there, but because they would have no chance of improving their wits, "by coming in contact with an enemy or a friend, so complex, dreadful, and ingenious as a human being." When not trained to be the companion of man, even the dog, as in some Eastern countries, is a very stupid animal. Many other facts appear to show that "man the thinker has to a considerable extent reacted on animals, wild and domestic."

The Irrepressible Spectroscope. — There seems to be no end to the applications of this marvellous instrument. It would be rash to say what question in science it may not be the means of settling. It has lately proved, either that chlorophyl is not, as has been taken for granted, an exclusively vegetable product, or else that what have been considered as some of the lower forms of animal life are really to be classed as plants, since they contain a green coloring matter, which gives the same absorption bands as chlorophyl. It has also refuted the theory that chlorophyl is separable into two primary substances of a yellow and blue color, the xanthophyl and cyanophyl of Frémy.

LITERARY NOTES.

The Messrs. Harper, of New York, send us *The Malay Archipelago*, by Alfred Russel Wallace. This is a most beautiful and interesting book, full of thrilling narratives of adventures in the land of the orang-utan and the bird of Paradise. It presents fresh pictures of a country about which but little has been written, and therefore it will be welcomed by every reader. The Malay Archipelago includes three islands larger than Great Britain; and one of them, Borneo, is more than four times as large. The area of land embraced in the whole is larger than the continent of Europe, and the islands are covered with luxuriant tropical vegetation. Mr. Wallace's narrative of adventures will create a new interest in a hitherto unexplored country.

The same eminent house publish new editions of Dr. Worthington Hooker's Elementary Treatises upon *Chemistry* and *Natural Philosophy*, books of science suited to the school and family. Prof. J. C. Dalton's *Physiology and Hygiene* is a work which can be safely recommended for the use of students and general readers.

The Chemical Forces, Heat, Light, and Electricity, by T. R. Pynchon, M. A., just published by O. D. Case & Co., of Hartford, is a handsome volume of more than five hundred pages, and supplies a good introduction to Chemical Physics. What used to be known as the "Imponderables," are now better understood, not only in their relations to each other, but in their applications to the expansion, vaporization, &c., of solids, the steam engine, photography, spectrum analysis, the galvanic battery, electro-plating, the fire alarm of cities, telegraphy, &c., &c. The recent researches connected with light, heat and electricity, have a deeper interest, and are fraught with more important practical benefits, than any connected with other departments of scientific labor. This work of Professor Pynchon will serve a good purpose in supplying a text-book in which the most recent discoveries are presented in a clear and very concise manner.

Dr. C. Neidhard, of Philadelphia, published, in 1867, an important and exhaustive treatise upon Diphtheria, which has had a wide circulation. A copy has recently been sent to us, and we have been interested in the history of this terrible disease as presented by Dr. N. The work affords evidence of much research and careful observation, and is worth attentive examination.

A Winter in Florida, by Ledyard Bill, (New York, Wood & Holbrook, 1869), is a very pleasant account of the author's experience and observations in Florida during the winter of 1868 and 9. To the thousands of invalids and pleasure-seekers who are now turning their steps toward the land of the orange-tree and the magnolia, this narrative of travel will be of particular service, as it affords information which we regard as reliable and important.

One of the most attractive and instructive writers that our country has produced, is Donald G. Mitchell, of New Haven. The force and purity of language, the keen insight into character, the genuine humor, the good sense and knowledge of farm pursuits, displayed in "*My Farm of Edgewood*," have never been excelled in any publications, and the book is a great favorite in thousands of families. Mr. Mitchell is now editor of that charming journal, *Hearth and Home*, published by Messrs. Pettingill, Bates & Co., New York. If our readers desire a journal devoted to the Farm, Garden, and Fireside, which will be the delight of the household, let them subscribe for Hearth and Home.

The name "Country Gentleman" conveys to the mind impressions of dignity, quiet respectability, culture, good sense, accuracy; and all these most desirable traits are found in the *Country Gentleman and Cultivator*, published by Messrs. Luther Tucker & Sons, Albany. This is the leading agricultural paper of the country, and has that which it deserves, a large patronage. We always read the "*Country Gentleman*," and when it is misplaced, or lost in the huge pile of exchanges which come to the Journal office, all other duties are suspended until it is found. This journal is an honor to agricultural literature, and it is doing a great and good work in promoting the important interests of husbandry.

A growing interest in popular science is shown, among other indications, by the prominence given to the subject in the magazines of the day. "Science" is set forth as a special attraction in every new prospectus, and the names of scientific contributors are displayed in as large type as is allotted to the writers of poetry and fiction. Efforts are made to secure the aid of eminent men in this department, as in others, and their labor is liberally paid for.

Harpers' Monthly has always made popular science one of its leading features, and the articles have been ably written and admirably illustrated. The *Nation* has said that "the periodicals which the Harpers publish are almost ideally well edited," and their immense circulation shows that the verdict merely echoes that of the *nation*.

Appleton's Journal is devoted to "literature, *science*, and art." A good share is given to science, and the matter is invariably excellent. As in the case of *Harpers'*, the illustrations add much to the interest and value of the articles.

The *Atlantic*, too, has from the first given *science* a prominent place on its cover and in its contents. Agassiz has been the leading name in this department, with others not unworthy to be associated even with him.

The *Galaxy*, which is taking a high rank among its rivals, announces that Dr. Draper and Dr. Dalton are to head the list of its scientific contributors this year.

Even the juvenile magazines are, in this respect, not behind those for older people. The *Riverside*—a model periodical of its class, externally and internally—begins the new year with an article on "Gunpowder Explosions," by Jacob Abbott, which is capital in its way. In writing for young readers, however, *we* should have said "ground to the finest powder," — or something of that sort, — rather than "reduced to a state of the most extreme comminution." But even Homer sometimes nods. *Our Young Folks* for January gives a sketch of the life of Agassiz, with a really good "counterfeit" of his genial physiognomy; and Mrs. Agassiz is to continue her account of the early history of "the world on which we live."

Personal. — Mr. J. A. Gillet, late of the Cambridge High School, and one of the editors of the popular "Cambridge Course of Physics," has been appointed Professor of Mathematics and Physics in the new Female Normal and High School of New York City, with a salary of $3,500 a year.

Medicine and Pharmacy.

FRACTURE OF THE LOWER THIRD OF THE HUMERUS FROM A FALL ON THE HAND.

BY M. M. SHEARER, *Act. Asst. Surgeon U. S. A.*

[Dr. Shearer sent to the JOURNAL, some months ago, the following interesting communication, but it was misplaced, and therefore did not appear. The surgical case is one that should not fail to be recorded, although not appearing immediately upon its occurrence.]

PRIVATE Lewis Wilhite, Battery B, 4th Artillery U. S. A., while walking rapidly over a raised porch facing the barracks at Fort Leavenworth, Kansas, reached the extremity in the darkness sooner than expected, and unconsciously stepping off a full pace, missed the steps and fell headlong to the earth.

The instinctive act of preservation, throwing the hands forwards, prevailed in this instance, and the right palm catching the entire weight of the body, conjoiued with the momentum acquired by the fall, produced an oblique fracture of the lower third of the humerus just above the condyles.

I have been thus explicit in stating *how* the fracture was occasioned, by reason of two standard authors, on dislocation and fractures, diametrically differing as to the etiology of this particular kind of fracture.

Dr. F. H. Hamilton, page 244, paragraph 6, says: "I have never been able to trace it to a fall upon the hand, but to an indirect blow inflicted upon the elbow!" Dr. Gross writes in his Surgery: "This fracture is more *frequently* occasioned by falls upon the palm of the hand in attempts to save the body from more serious injury." In this case there is no doubt whatever the injury resulted in the manner described by Dr. Gross. The patient, who was in entire possession of his faculties at the time, so explicitly states it, and could not easily have been mistaken. Besides, the palm was considerably bruised, while there was not an abraded spot anywhere on the arm. A small amount of ecchymosis was discernible on the internal surface of the joint, produced by the extremity of the fractured bone.

Did not see the case for sixteen hours after the occurrence of the accident, the patient failing to report himself immediately, supposing it to be "only a sprain!" In consequence, immense tumefaction presented, the infiltration obscuring perfectly the osseous structure of the joint, and extending as high as the middle third of the humerus. Our diagnosis, therefore, as to whether dislocation existed conjointly, was considerably retarded.

Upon a cursory inspection, we first supposed it to be luxation of the ulna backwards, the projection of the olecranon process in that direction being very marked. The impression was corrected, however, upon manipulation, by remarking the condyles still in a line — from side to side — with the process. The whole three, lacking osseous support just above the condyles, were tilted backwards by action of the triceps. These symptoms, together with distinct crepitation, and a lateral movement of the member above the joint, with diminished length from elbow to shoulder, decided us as to an oblique fracture from before backwards; likewise its exact location and direction. The patient being completely anæsthetized by chloroform, a careful and extended examination was made for detection of dislocation of radius, an exceedingly obscure point to determine where much tumefaction exists. Being satisfied as to non-impairment of the joint through dislocation, extension was made, the fractured extremities brought into juxtaposition, obtuse angled splints adjusted anteriorly and posteriorly, and a roller applied from the tips of the fingers to the shoulder. The patient, having rallied splendidly from the effects of the anæsthetic, was put to bed, and a constant application of cold water to the affected limb enjoined for several days.

Up to this date the swelling has greatly subsided, osseous union has taken place kindly and firmly, betokening a speedy recovery and use of the member.

In the great majority of such accidents, violent falls upon the palm occur when the arm is in a partially flexed condition, the elbow raised from the hand, flexed horizontally to the body, instinct as it were, prompting the person falling to instantaneously so place the limb, in order to avoid a direct and more serious shock to the body, which would follow were the arm in a perfectly straight and rigid position.

In this semi-flexed condition, the force of the blow, following a straight line in the direction of an axis drawn perpendicularly to the palm or carpal extremity of the metacarpal bone of the middle finger, would emerge at the middle or lower third of the forearm, producing fracture of one or both bones in this locality. But supposing the arm *straight*, — a rare condition, I admit, but possible, — then certainly the force extends throughout the entire axis of the limb, when the weakest point succumbs. This undoubtedly will be either fracture of the lower third of the shaft of the humerus, or disarticulation of the shoulder joint. Again, the blow striking as above described, — arm semi-flexed, — might follow a straight line with the axis of the forearm, when the lower third of the humerus, receiving it obliquely, would be fractured. In either case, we can always look, as a result of accidents of this kind, for fracture above the condyles.

IMPROVED FORMULA FOR CHALK MIXTURE.

Ed. Boston Journal of Chemistry:

CHALK mixture, the *mistura cretæ* of the Pharmacopœia, is one of the remedies most frequently employed in the summer complaints of children. Yet, as commonly prepared, its use is attended with both inconvenience and danger. The mixture ferments with the greatest ease in warm weather, and the supernatant liquid becomes sour or mouldy. The mixture also ferments frequently in the stomach after administration. This is entirely obviated by substituting glycerine for sugar, according to the following formula:—

Take of Prepared Chalk and Glycerine, each, *half an ounce;* Gum Arabic in powder, *two drachms;* Cinnamon Water and Water, each, *four fluid ounces.* Rub them together until they are thoroughly mixed.

This mixture will readily keep during a whole summer. I recently had occasion to administer some of the mixture prepared as above, which had stood for three or four months during the hottest weather, and found it in perfect condition.

The diarrhœa of children in hot weather is generally accompanied, if not caused, by fermentation. Sugar is therefore contra-indicated. But glycerine seems to exert a positive soothing action upon the bowels, as well as, in some degree, to arrest fermentation.

The substitution of glycerine for sugar, in the proportion of two parts of the former to one of the latter, ought to be made in all sirups, elixirs, mixtures, which are subject to fermentation. The *mistura cretæ* may be taken as an illustration.

Glycerine may be used with great advantage to replace sugar in the food of children or adults, where there is enteric irritation or inflammation. Under these conditions of great local heat and excitement, sugar almost always ferments and acidifies. Pure glycerine, on the other hand, does not ferment, is bland, and at the same time a concentrated nourishment. In a recent case of severe gastric irritation or enteritis of an infant only three months old, fed by hand, the writer gave from four to six drachms of glycerine daily for a fortnight in place of sugar, with rice-water or porridge. Here the glycerine constituted a considerable portion of the nourishment taken. The result was entirely favorable, where it would probably have been fatal, if a fresh amount of acid from fermented sugar had been periodically introduced into the bowels.

Familiar Science.

TORPEDOES IN WARFARE.

EVER since the discovery of the explosive properties of that mixture of nitre, carbon, and sulphur known as gunpowder, the modes and instruments of war have been constantly changing. There is as great a difference between the arquebus and culverin of former days, and the breech-loading magazine rifle and columbiad of the present time, as there is between one of Columbus's caravels and a modern iron-clad. Progress has steadily gone on from small, uncertain weapons, to the terribly destructive rifles, needle-guns, and monster ordnance now so common. The problem is to apply explosive force so as to combine certainty with completeness. Nevertheless, in battles, vast quantities of powder and shot are expended that do not produce the slightest effect. Forts are constructed for the defence of a coast, and navies are built for offensive and defensive purposes, but in spite of the enormous sums lavished on such works, we are constantly finding that new discoveries and improvements are making them less and less valuable, if not useless. Fortifications of granite or brick are now almost despised; there are very few such fortresses that could not be quickly battered into ruins by the artillery now in use.

So, also, iron-clad war vessels must be built, in order to counterbalance the increased destructive power of ordnance, by increasing the resistance offered to the shot. Numberless experiments have been tried, having in view the construction of some combination of materials that will successfully withstand heavy artillery. In England, especially, great sums have been expended in making and setting up targets to be knocked to pieces. It has been a question of considerable moment for some years past, which of the two sides, the offence or the defence, the gun or the target, would come out victor. The question still remains unsettled, since in such experiments many very important considerations are neglected. The subject of plating vessels with armor is very complicated, and involves many problems which are not solved by determining experimentally what thickness of iron will be proof against a particular kind of attack. In our monitors, we think that we have a war vessel better than any other form of iron-clad; yet they are not really good sea-boats. Though some of them have crossed the ocean, nevertheless it will be admitted that they are not adapted for cruising. Supposing it to be granted, however, that an iron-clad can be so built as to be impenetrable to shot from the largest cannon, and still possess all the other qualities required of a ship of war, yet such a vessel can be entirely destroyed in an instant by exploding a comparatively small amount of powder *under her*.

No armor will resist explosive force thus applied. This consideration is a very important one, since the destroying agent in such case is insignificant in comparison with the effect it produces. It will be readily seen that the possibility of making such a use of explosives opens a very interesting field of inquiry. This subject is one which is attracting a great deal of attention at the present time, and all the principal maritime nations are more or less concerned in its investigation. In the event of another war, torpedoes will play an important part in naval encounters. We propose, therefore, in the following paragraphs, to submit to our readers some remarks upon the subject of torpedo warfare.

The use of torpedoes in warlike operations is not really new, but they never have been so extensively applied to such purposes as during the civil war in this country. David Bushnell was the inventor of the torpedo. Becoming interested in the subject of submarine warfare, he devoted all his time and property to it. His plan consisted of a "submarine vessel" provided with a "magazine and its appendages, designed to be conveyed by the submarine vessel to the bottom of a ship." The boat would carry but one person, and contained sufficient air to enable him to remain under water half an hour. By expelling or admitting water, the boat could be raised or lowered at pleasure. The magazine or torpedo contained one hundred and fifty pounds of powder and a train of clockwork, which would, at the expiration of the time for which it was set, move a lock like a gun-lock, and thus explode the charge. The vessel floated low in the water, so that in the night a ship might be approached very nearly; and then, by going down, the operator could come close beneath without discovery. He could then fasten his torpedo to the bottom, set the clockwork in motion, and make off himself.

Bushnell tried many experiments with his submarine boat and torpedo which were successful. He next tried to put his inventions into practical use, by making an attempt to blow up the British ship Eagle, of sixty-four guns; but, though the operator succeeded in getting under her, he could not, for some reason, fasten his torpedo, and so failed. Two other attempts were afterwards made, but were also unsuccessful. Bushnell seems to have had very great difficulties to overcome. His health gave way, and, from the exigencies of public affairs, he was unable to obtain the requisite attention to his inventions. He did not confine himself entirely to this form of apparatus, but prepared another very ingenious one, with which he tried to blow up the British frigate Cerberus, by working it against her side by means of a line. It so happened, however, that it came in contact with a schooner, which he did not see, belonging to the frigate, and anchored just astern of her. The sailors on the schooner drew the machine on board, when it exploded, destroying the vessel, and killing three men.

Shortly after, he filled several kegs with powder and set them floating down the Delaware, toward the British fleet at Philadelphia. They were so contrived that upon touching anything, explosion would take place. But being unacquainted with the river, he set them off too high up, so the greater num-

ber did not reach their destination. One of them was taken on board a boat and blew it up. In consequence of this attempt of Bushnell's, the celebrated "Battle of the Kegs" took place. Bushnell's inventions displayed originality and ability, but everything seemed to work badly, so that at last, bitterly disappointed, he gave them all up.

Twenty years later, Fulton tried to revive the matter. In 1797, he offered to the French government a machine "to impart to carcasses of gunpowder a progressive motion under water to a given point, and there explode them." It was then rejected, but, soon after, he offered in addition another form of apparatus — a diving or plunging boat. By direction of Napoleon, experiments were tried with them, but although not unsuccessful, Fulton was unable to induce the French government to adopt his plans. He then carried them to England. Pitt, the Prime Minister, was interested in them, and gave him an opportunity to test them. Several failures occurred, and they were pronounced impracticable. At last, Fulton made, after several trials, a perfectly successful experiment. With one hundred and seventy pounds of powder, he blew up a stout brig, completely destroying it. Nevertheless, he could not persuade the English government to prosecute his schemes.

Coming to this country, he laid them before the authorities. A commission was appointed to test them practically. The experiments were not very successful, but some of the commissioners were strongly impressed with the importance of the subject. One of them said, "The submarine use of gunpowder will at no distant day be entitled to rank among the best and cheapest defences of forts and harbors." Nevertheless, no further investigations were made. The opposition to such outrageous and new-fangled notions was altogether too strong. During the war of 1812, quite a number of attempts were made by individuals to blow up British vessels, but without very striking results. They excited, however, very great alarm among the British cruisers, making them very watchful and suspicious, and also chary of entering harbors.

Colt, the inventor of the revolver, was the next person to follow in the footsteps of Bushnell and Fulton. The progress of discovery had furnished many ideas which, applied to the torpedo, greatly increased its effectiveness. Fulton had thought of employing the electric current as a means of explosion, but considered it impracticable. Colt actually applied it, and by its means made a number of successful explosions. He also tried to interest the government in his system, and, in 1842, Congress made an appropriation of $17,000 to continue his experiments, which were attracting a great deal of attention. But, as in Fulton's time, the opposition was too strong, and the whole thing was finally dropped.

The Russians, during the Crimean war, used great numbers of torpedoes, but the Allied fleets were very careful, and met with but very few accidents from them. They were, however, unquestionably a valuable means of defence; and that they were dangerous was shown by the fact that two British vessels came very near being destroyed by them. But all the cases we have mentioned are but of trifling importance, in comparison with the extensive use to which torpedoes were put during the late war in our own country.

From the very beginning of the conflict, the Union forces greatly predominated in naval power. This was a very great disadvantage to the rebels, since the extent of their coast-line, and the number of navigable streams opening upon it, invited naval attack. Their seaports were captured or effectually blockaded by our vessels. They had no navy with which to oppose ours, so they were compelled to find some other means of defence against our gunboats, or at least some way of making their entrance into and passage up harbors and rivers more difficult and dangerous. Obstructions could, of course, be placed in narrow rivers, but, besides being very limited in their application, they had the disadvantage of preventing the passage of friends as well as foes.

A torpedo system was therefore devised and very rapidly put into execution, which went far towards attaining the desired end. Torpedoes of all sorts were constructed, put into use, and soon began to demonstrate their destructive powers. It is in consequence of the success achieved by the rebels in this direction, that the importance of this branch of warfare has come to be recognized. We shall, therefore, try to give a short account of some of the details of their system. Our readers will remember that, through '61 and the early part of '62, the operations of our navy had been very successful. An efficient blockade had been kept up, and a great part of the Atlantic coast occupied. No torpedoes had thus far been met with. They were first observed in February, 1862, by some gunboats endeavoring to pass up the Savannah River. They were planted so as to be seen at low water, but at all other stages of the tide, would be entirely covered. Fortunately, they were noticed and removed by exploding them. Later in the year, almost all the narrow rivers on the coast were supplied with torpedoes of various constructions, but as yet no regularly organized system had been put into operation. In October, '62, however, by act of the rebel Congress, a secret service corps was organized, and soon torpedoes might be found in any of the waters under rebel control. Different forms of torpedoes were used according to circumstances; but most of them may be classified by division into *frame*, *buoyant*, and *electric* torpedoes.

[*To be continued.*]

THE DISTANCE OF THE SUN.

A correspondent in Iowa does not understand how the solar parallax of 8.58", as given by Mitchel in 1860, has been changed to 8.94" by some recent authorities, making a difference of almost 3,500,000 miles in the sun's distance from the earth. He says: "As the solar parallax is determined by observations on the transit of Venus, and as the last transit occurred in 1769, I am puzzled to know how the correction has been made."

It is true that the parallax as obtained from the observations of the transit of 1769 was 8.578", but a careful re-calculation, *from the same observations*, has recently given 8.91". Within a few years, moreover, several determinations of the parallax have been made by independent astronomical methods; and the values obtained range from 8.91" to 8.97". The new value obtained by Hansen, from the moon's parallactic equation, is 8.916"; by Winnecke, from the observations of Mars, 8.964"; by Foucault, from the velocity of light, 8.96"; and by Leverrier, from the motions of Mars, Venus, and the moon, 8.95". The distances corresponding to these values range from about 91,300,000, to 91,850,000. The distance 91,430,000 is adopted by many of the best astronomers, and is undoubtedly correct within 200,000 miles.

Gravity Below the Earth's Surface. — We have received from Mississippi a long communication on this subject. The writer says: "It is a settled fact, I believe, that all bodies in space are mutually attracted, directly as their masses, and inversely as the square of the distance. The same law is supposed to hold good from the surface to the centre of masses of matter." He then goes on to disprove the latter proposition, and to show that beneath the surface of the earth, the attraction diminishes directly as the distance from the centre. He is clearly correct in his demonstration, but we were not aware that the contrary view had ever been maintained. All the authorities, so far as we know, — even the common school-books,— agree in stating that below the surface the attraction diminishes (that is, it is partly counterbalanced by the attraction of the portions of the earth outside), until at the centre the attractions in all directions are equal, and a body virtually weighs nothing. The assertion which our friend quotes, to the effect that if there were a hole through the earth, a body dropped into it would go *beyond* the centre, does not conflict with this view: it would go beyond the centre, *not* because of the increasing attraction, but because of its *momentum*, —just as a pendulum swings beyond the lowest point of its curve, on account of the impetus it has acquired in descending to that point.

It does not follow, from the law of attraction mentioned above, that the *density* of the earth must be greatest at the surface and least at the centre, as our correspondent argues; but it is hardly worth while to show up the fallacy of his reasoning on this point.

THUNDER AND LIGHTNING.

A correspondent in Michigan sends us the following speculations as to the causes of these phenomena:—

"The commonly accepted theory of thunder is, that lightning, in passing through the air, separates it, causing a vacuum; and the concussion of the recoiling air upon itself sets it into sonorous vibration. If this were so, any body passing rapidly through the air, as cannon and rifle shot and falling meteoric stones, would produce a sharp report. I think the vacuum comes from another cause, and one purely chemical.

"Lightning is conducted to the earth, and from cloud to cloud, by the intervening watery vapor. The water along its course is decomposed; the hydrogen, mixing with atmospheric air, is ignited by the electric heat, or perhaps the heat of friction, producing an explosion and a track of fire along the whole electric course. It is a fact of common observation, that lightning more often strikes and more violently rends trees that contain the most of acid sap, such as black and white oak, elm, hemlock, etc. (beech and maple being almost exempt), because such trees are good conductors, while dry-wooded ones are not. The acid condition of the sap materially assists the decomposition of its water into many volumes of its constituent gases, hydrogen and oxygen; hence the more perfect destruction of such trees. I believe the great heat evolved by lightning depends more upon rapid chemical changes, such as decomposition and combustion, than any property of heat possessed by electricity. The report, too, compared with all better understood phenomena, is one of detonation."

Liquids as Conductors of Heat. — The form of apparatus for showing the feeble conductibility of liquids, which a correspondent describes, is very good; but the same fact may be shown even more simply by holding the upper part of a long test-tube full of water over the flame of a spirit lamp or Bunsen's burner. The water at the top of the tube can thus be boiled, while the lower end of the tube is held in the hand. If a small piece of ice is put at the bottom of the tube

(where it can be kept in place by a bit of wood or cork, across the tube), the experiment is even more striking, as the water can be boiled without melting the ice. In that admirable little book, "The Wonders of Heat," by Cazin (published by Scribner, of New York), our correspondent will find a number of these experiments described and figured.

ICE MOUNTAINS AND CAVERNS.

THE ice mountain in Virginia, described by Mr. Hayden in Vol. 45 of the American Journal of Science, is an instance of the fact of ice being preserved under the surface. An immense mass of *débris*, the stones varying in size from a few inches to many feet, rises several hundred feet against a rocky wall. The interstices are filled with ice, which is preserved there in the summer as in a vast refrigerator.

An ice mountain also exists at Wallingford, Vt., where a wall of quartz rock has a space of more than thirty acres at its base, covered with loose fragments, and ice occurs in a ravine in which these fragments have been cast. Ice also is constantly found in the elevated ravines of the Catskill and White Mountains.

The ice caverns of Europe and Asia also present phenomena allied to these frozen strata discovered in wells. Prof. Pictet, of Geneva, describes in the Edinburg Philosophical Journal, in 1823, four of the grottoes examined in the Alps and the Jura. Each of these had upon the bottom a surface of about 3,000 feet of ice, of the thickness of a foot. When this was quarried during the summer, it constantly renewed itself by freezing. Strong currents of cold air constantly issued from these caverns, and the strength of the current seemed to increase with the heat of summer. Water was found in them all, and the air was loaded with vapor. The freezing in these caverns is explained by the descent of currents of air into the caverns in summer, and their escaping at the bottom. These currents in their descent part with their heat, and acquire the temperature of the surrounding rocks, and if these be covered with moisture the evaporation diminishes the temperature. In winter the current ascends, and the evaporation being less, the cold is not so intense. Sir R. J. Murchison, in his Geology of Russia, has described some frozen caverns existing at Orenburg and Indursk, on the Siberian side of the Ural Mountains. These are similar to the caverns described by Prof. Pictet, excepting that the freezing, for the most part, takes place in summer, while in winter the ice thaws.

There is an old iron mine at Port Henry, on the west side of Lake Champlain, in which ice is found at a depth of from thirty to one hundred feet during the summer, and a current of cold air issues from the opening. Ice is also found in a cavern in a hill about two miles north of Brandon village. — *Aaron Lloyd, in Hours at Home.*

SEEING WITHOUT EYES.

IT is fully established that somnambulists go wherever they please without hesitation, read and write, and give ample evidence of a power of perception independent of the usual organs of vision. Persons subject to attacks of catalepsy frequently show the same peculiarity. M. Despine, late inspector of the mineral waters of Aix, in Savoy, mentions the following among many other cases: "Not only could our patient hear by means of the palm of her hand, but we have seen her read without the assistance of the eyes, merely with the tips of the fingers, which she passed rapidly over the page that she wished to read. At other times we have seen her select from a parcel of more than thirty letters the one which she was required to pick out; also, write several letters, and correct, on reading them over again, always with her finger ends, the mistakes she had made; copy one letter word for word, reading it with her left elbow, while she wrote with her right hand. During these proceedings a *thick pasteboard completely intercepted* any visual ray that might have reached her eyes. The same phenomenon was manifested at the soles of her feet, on the epigastrium, and other parts of the body, where a sensation of pain was produced by the mere touch."

Persons who have become blind have also been known to acquire the same power, and Harriet Martineau tells of an old lady who had been blind from her birth, and yet saw in her sleep, and in her waking state described the color of the clothing of individuals correctly.

In these cases, no doubt, perception is, as usual, in the brain; but either all the nerves of the surface have the power of conveying the impressions of light to that organ, or some special parts of the body, as the ends of the fingers, the occiput, or the epigastrium, assume the office of the eyes. — *Dr. Clark, in Hours at Home.*

SCHÖNBEIN'S TEST FOR PRUSSIC ACID.—It is stated by Mr. Welborn in the London *Pharmaceutist*, that Schönbein's test paper, described in the JOURNAL for November, is equally sensitive to the action of chlorine, and, in a less degree, to that of nitric acid vapor. This does not, as Mr. W. assumes, make the test worthless. It merely complicates the testing process; as in Marsh's test for arsenic, where the black spot on the porcelain *may* be produced by antimony as well as by arsenic, and further tests must be employed to decide the question.

Arts.

THE METALS OF THE HOMERIC AGE.

"JUVENTUS MUNDI, or the Gods and Men of the Heroic Age," by the Right Hon. W. E. Gladstone, (Macmillan & Co., London, 1869,) is a minute study of the times of Homer through the medium of the Homeric poems. Every chapter is of the highest interest to the classical scholar, and parts of the work will have an attraction for the scientific student as well. We cannot resist the temptation to quote a few paragraphs from the section on "Metals in Homer": —

"Archæological inquiry is now teaching us to investigate and to mark off the periods of human progress, among other methods, by the materials employed from age to age for making utensils and implements, and the poems of Homer have this among their peculiarities: they exhibit to us, with as much clearness, perhaps, as any archæological investigation, one of the metallic ages. It is, moreover, the first and oldest of the metallic ages, the *age of copper*, which precedes the general knowledge of the art of fusing metals; which (as far as general rules can be laid down) immediately follows the *age of stone*, and which in its turn is often followed by the *age of bronze*, when the combination of copper with tin has come within the resources of human art.

"The grand metallic operation of the Poems is that of Hephaistos in the production of the shield of Achilles. The metals used were gold, silver, tin and *chalcos*, which has been, by mere license of translators, interpreted as *brass*, for there was no brass till long ages after Homer's had rolled away: which has been more plausibly taken to mean *bronze:* but which, after a good deal of inquiry, I am satisfied can only mean *copper*, either universally and absolutely, or as a general rule, with very insignificant exceptions. . . .

"In the formation of the shield, there is no mixture or fusion of metals. The same, and all the same, which are put into the roaring fire, re-appear, each by its original name, in various portions of the shield. . . . There is no sign of founding or casting in this great masterpiece of Hephaistos. He could only mix by melting; and had he melted metals, we must have heard of moulds to receive them. Instead of this, the only instruments which he makes ready for the work are,

1. The anvil.
2. The hammer in his right hand.
3. The pincers in his left.

It is plain, then, that he was supposed not to melt, but only to soften the metals by heating, and then to beat them into the forms he wished to produce.

"Had Homer been conversant with the fusing or casting of metals, this is the very place where we must have become aware of it, especially as his works of skilled art are all of Phœnician origin or kin, and his Hephaistos is a god of Phœnician associations.

"If *chalcos* be not copper, then copper is never mentioned in Homer. But in an early stage of society, copper was commonly by far the cheapest and most accessible of metals; and it is quite impossible to suppose that we never once hear of copper from an author, who incessantly makes mention (so it is argued) of another metal, whereof it is by far the largest component part. . . .

"We find *chalcos* in Homer a very cheap and common metal; tin a very scarce and rare metal, only used in very small quantities, and even approaching in some degree to the character of what we now term a precious metal. It is very improbable that the defensive armor, and all the meaner utensils in Homer, could have contained an eighth part, or thereabouts, of tin. . . .

"It is said that copper cannot be hardened so as to make a cutting tool; whereas *chalcos* is named in Homer as used for peeling bark, and cutting twigs and young branches, as well as for making weapons of war. . . But as portions of tin are found in some copper ores, may it not be that there are also small portions of it in virgin copper used for these purposes? I find, moreover, that ancient nails have been discovered, containing ninety-seven and three-fourths per cent of copper, and only two and one-fourth of tin: and surgical instruments made of copper alone have been discovered recently in a tomb in Athens. . . .

"Silver appears to have been rarer than gold: as might be expected, considering that it is chiefly obtained by scientific means. It came but from one place, Alube in Asia Minor. We do not hear of it as used in exchange, nor, I think, in stored wealth; but in plating only, and in works of art. . . . Of lead we hear very little indeed. Iron was greatly more esteemed than copper, and was very rare, though seemingly more abundant than tin. We hear of it, together with gold and copper, as an article of stored wealth. It was only used for cutting instruments; and chiefly, as far as appears, for woodmen's axes. The quantities of all the metals would seem to have been very limited, except of *chalcos* only. . . . Tin was used for ornament, and was plated on copper. The only articles entirely made of it were the greaves of Achilles; and these proceeded from a divine not a human workman."

THE METRIC SYSTEM.

WE have seen communications in some of the medical journals, complaining of the use of the metric system in the books and periodicals of the day, because of the difficulty of changing the foreign denominations to our familiar ones. We cannot believe that any one who has perceived the simplicity of *plan* in the metric system, need have any trouble in *translating* its weights and measures into those commonly used among us. All that is necessary, is to note the way in which the *names* are formed, and then to fix in the memory the value of some *one* denomination in each table.

The *names* are formed on the following plan : —

The names of the *higher* orders, or the *multiples* of the standard unit (*metre, gramme*, or *litre*), are formed from the name of that unit by means of prefixes taken from the *Greek* numerals, namely: *deca-* (10), *hecto-* (100), *kilo-* (1000).

The names of the *lower* orders, or the *subdivisions* of the standard unit, are formed in a similar manner by means of prefixes taken from the *Latin* numerals, namely: *deci-* (10), *centi-* (100), *milli-* (1000).

Now, if we have learned this simple nomenclature, we have only to learn the value of the three standard units, and we can then readily figure out the value of any weight or measure that we meet with. For instance, the *mètre* is 39.37 inches. We can fix that in our memory, or call it *3 feet, 3¼ inches*, which is near enough for most practical purposes. A *décimètre* is, of course, *one-tenth* of that; a *millimètre* is *one thousandth*; a *kilomètre* is a *thousandfold* greater, etc.

If you prefer it, you can cut out (or copy upon a card, if you do not wish to mutilate the paper), the following brief tables, which give the English equivalents established by Congress in July, 1866: —

LINEAR MEASURE.

1 centimètre	=	0.3937 inch.
1 décimètre	=	3.937 "
1 *mètre*	=	39.37 "
1 décamètre	=	393.7 "
1 hectomètre	=	328 ft. 1 inch.
1 kilomètre	=	3280 " 10 "

MEASURES OF CAPACITY.

1 centilitre	=	0.6102 cubic inches.
1 décilitre	=	6.1022 " "
1 *litre*	=	1.9567 wine quarts.
1 décalitre	=	2.6417 " gallons.
1 hectolitre	=	26.417 " "
1 kilolitre	=	264.17 " "

WEIGHTS.

1 centigramme	=	0.1543 grains.
1 décigramme	=	1.5432 "
1 *gramme*	=	15.432 "
1 décagramme	=	0.3527 oz. avoirdupois.
1 hectogramme	=	3.5274 " "
1 kilogramme	=	2.2046 pounds "

The following simple rules for the conversion of the linear measures (which have probably never been published in this country) will be found convenient:—

"To change kilomètres to miles, multiply by 5 and divide by 8. To change mètres to yards, multiply by 35 and divide by 32. To change décimètres to feet, divide by 3. To change millimètres to inches, multiply by 4, and point off the last two figures. To change miles, yards, feet, or inches, into metric equivalents, multiply by the divisors, and divide by the multipliers, as just given."

As the *kilogramme* is very often used, it is well to recollect that it is 2 1-5 *pounds;* or, for ordinary cases, 2 *pounds* will be near enough. In like manner, the *litre* may generally be reckoned as a *wine quart*.

Some of our readers may not know that they have a key to the tables of linear measures and of weights, in the five-cent piece of our recent coinage. The diameter of that coin is 2 *centimètres*, and its weight is 5 *grammes*. Five of them placed in a row will, of course, give you the length of the *décimètre*; and two of them will weigh a *décagramme*.

As the *kilolitre* is a *cubic mètre*, the key to the measures of length is likewise the key to those of capacity: so that any man who is the happy owner of a five-cent bit may carry in his pocket the entire metric system of weights and measures.

CARBOLIC ACID FOR PRESERVING SPECIMENS.—At a recent meeting of the Chicago Academy of Sciences, Dr. Stimpson gave the result of three months' experiments upon carbolic acid as a substitute for alcohol, in the preservation of wet specimens. He found that deliquesced crystals of the acid, dissolved in forty times their bulk of water, gave a fluid which equalled alcohol in its preservative qualities, at less than one-twentieth its cost, with the additional advantage of keeping the specimen far more nearly in its original condition. In a solution of twice that strength, the specimen itself is soon destroyed. Specimens should be first placed in a very weak solution, say one-half per cent; but as the action of the acid is very rapid, it may be daily changed for a slightly stronger one, until the full strength (two and one-half per cent) is reached. This should be done to prevent the contraction resulting from the sudden contact of a strong solution, and preventing endosmosis. Fluids once used will be found to have lost their preservative power far more than alcohol, and must be strengthened before being used again. The freezing of the fluid may be prevented by the addition of one-eighth part of alcohol. If the smell of carbolic acid, which is very slight in the weak solutions, should be objected to, the addition of a minute quantity of the oil of wintergreen will cover it completely.

Agriculture.

S. L. GOODALE ON COMMERCIAL FERTILIZERS.

IT must be confessed that for the year past we have been living quite in the dark regarding the existence of some agricultural literature of a rather remarkable character, which the Secretary of the Maine Board of Agriculture has given to the world. The author, strange to say, did not remember us when his production was published, and we are indebted to a friend for a copy of an address upon Commercial Fertilizers, delivered before the Farmers' Convention at Augusta, Jan. 1869, by S. L. Goodale, Secretary of the Maine State Board of Agriculture.

Coming, as this document does, from one who holds an important official connection with the agriculture of a great State, we had a right to expect to find in it some suggestions of practical value, or at least the presentation of some facts, or some advice, of a useful character, and promotive of the general interests of husbandry. We are sorry to say that in this we are disappointed. Mr. Goodale, it appears, is acting in a double capacity: he is engaged in making commercial fertilizers, and serving as secretary of the Board of Agriculture. If any of the good farmers of Maine have ever suspected that there might be a certain degree of incompatibility in the two vocations, this pamphlet furnishes abundant proofs that their suspicions were well grounded. The interests of the "superphosphate" maker appear to preponderate over those of the secretary. Mr. Goodale claims to be a chemist, and to show how he came to be one, he states that "when a lad his favorite play-room was a laboratory, and that more money went for chemicals than for jack-knives and skates"; and that since he "was a lad", or since he became secretary, "he has endeavored to keep within hailing distance of the science, and on speaking terms with it." Any man who spent more money for "chemicals" than for "skates and jack-knives," when a boy, and who in manhood "keeps within hailing distance of the science," is certainly competent to act as chemist to the "Cumberland Bone Company," and also to criticise, overturn, and demolish any statement made in this, or other journals, which conflict with the interests of the said "Bone Company." The secretary further informs us, in his address, that "latterly he has given *some* thought to *business*": not the business of the secretaryship, but that of "phosphate making." Very well; we think we understand him.

Nearly three pages of this address are devoted to criticism of this JOURNAL and its editor. The article published by us in the number for April, 1868, upon "*Superphosphates*," is particularly offensive to him, and he comments upon it at length. In this article, our readers will recollect that in reply to the inquiries of farmers, "where they can procure genuine 'superphosphates,'" we state that we do not know of any *true* article for sale in the market. There is no brand that we can recommend as being fully up to a proper, scientific standard, and we advise farmers to make their own "superphosphates," as we do upon our farm. This does not suit the phosphate-making secretary, and he proceeds to inform us that "within ten minutes' walk of the JOURNAL office, there can be found a ton, or a hundred tons of good quality, which can be had for a fair price." This means, we suppose, that the "Cumberland Bone Company" had a stock of their products within ten minutes' walk of our office, when the paragraph was written. Of this important fact, we were certainly ignorant, and therefore beg pardon. We never heard of the "Bone Company" before the address fell into our hands. This "superphosphate," compounded under the supervision of the chemical secretary, he informs us, "has an addition made for the purpose of rendering it repellant to vermin in the soil, infesting plants, like wire-worms, onion maggots, etc." What it is, he does not inform us. As secretary he ought to have named the "addition"; as bone-grinder and chemist, he has a right to keep the great secret, or even to patent it if he chooses to do so.

This statement is made by way of explanation, or apology for an "unpleasant odor" which the compound has, and we are left to infer that the article "repellant to maggots and worms" is not grateful to the olfactories.

The secretary explicitly advises farmers *not* to make their "superphosphates." Of course, after this disinterested advice from so high a source, farmers will give up all experiments, all attempts to dissolve bones, and—buy the secretary's genuine mixtures. Not being in the phosphate-making business, we *have* advised farmers to manipulate their own bones, and manufacture their own fertilizers, but—we stand rebuked.

This document, with the name of the secretary upon it, stands on the same level with similar business circulars, or advertisements, and must go into the waste basket along with other rubbish. We understand it has been very extensively distributed to the farmers, at all the agricultural meetings in Maine, New Hampshire, and elsewhere, during the past year, and therefore we have felt called upon to notice it. In conclusion, we can only say, that if the farmers of Maine are to have their official documents and agricultural literature scented with the odor of the "phosphates" of any "Bone Company," we sincerely hope the "dead cat" flavor may be less offensive than is found in the article usually met with in commerce.

ROMAN AGRICULTURE.

FAULT has been found with history, that while it tells a good deal about a few leading characters, it gives us very little information about the masses of the people. We thus get a partial and often a perverted idea of the real life and spirit of a nation or a period. The history of Rome, for instance, as it appears in most of the books, is merely a succession of battle-pieces. War and conquest, and politics as connected with war and conquest, make up the bulk of it. The soldier and the statesman are almost the only actors that appear on the stage. We take it for granted that there must have been Roman tradesmen, and mechanics, and farmers, for we cannot imagine how the rulers and the warriors could get along without them; but we do not see that otherwise they are of any importance to the great drama. Especially would it surprise most persons to be told that agriculture was a recognized force in Roman polity, and that the farmer was made the direct ally of the soldier in the work of conquest. This, however, is clearly shown by Mommsen in his admirable "History of Rome," which is now made accessible to American readers by Scribner and Co.'s cheap but excellent reprint of the English translation. The following is a paragraph from the chapter on "Agriculture, Trade and Commerce," in the first volume:—

"The beautiful custom of commencing the formation of new cities by tracing a furrow with the plough along the line of the future ring-wall shows how deeply rooted was the feeling that every commonwealth is dependent on agriculture. In the case of Rome, in particular, the Servian reform shows very clearly, not only that the

agricultural class originally preponderated in the state, but also that an effort was made permanently to maintain the body of freeholders as the pith and marrow of the community. . . The whole policy of Roman war and conquest rested, like the constitution itself, on the basis of the freehold system; as the freeholder alone was of value in the state, the aim of war was to increase the number of its freehold members. The vanquished community was either compelled to merge entirely into the yeomanry of Rome, or, if not reduced to this extremity, it was required, not to pay a war contribution or a fixed tribute, but to cede a portion (usually a third part) of its domain, which was thereupon equally occupied by Roman farms. Many nations have gained victories and made conquests as the Romans did, but none has equalled the Roman in thus making the ground he had won his own by the sweat of his brow, and in securing by the ploughshare what had been gained by the lance. That which is gained by war may be wrested from the grasp by war again, but it is not so with conquests made by the plough. While the Romans lost many battles, they scarcely ever, on making peace, ceded Roman soil; and for this result they were indebted to the tenacity with which the farmers clung to their fields and homesteads. The strength of man and of the state lies in their dominion over the soil; the greatness of Rome was built on the most extensive and immediate mastery of her citizens over her soil, and on the compact unity of the body which thus acquired so firm a hold."

FARM ACCOUNTS.

The methods and results of farming are in general so defective and unsatisfactory, that a large amount of "moral courage" is deemed necessary fairly to face accounts at the end of the year, and look over the balance-sheet. It may be said, and with much truth, that most farmers have no accounts to examine, and as to a "balance-sheet," they do not know the meaning of the term. It is, indeed, a pity that farmers give so little attention to book-keeping in connection with their vocation. The value of a systematic, careful record of labor performed, and of crops, purchases, and sales, and also of the weather from day to day, has never been properly estimated. A man cannot have much self-respect, nor be mindful of his true interests, who does not use his pen daily in keeping accurate accounts of receipts and disbursements. Those who do not do this rest upon an unsubstantial basis; everything is at loose ends, and they become the easy victims of fraud and dishonesty.

Farm books should be systematically arranged and carefully kept. We should know at the end of the year how the account stands. No matter whether the balance is on the right or wrong side of the ledger, there is high satisfaction in knowing the truth; if we have made mistakes, or met with misfortunes, we want to have the facts recorded for our better guidance in the future; if we have been successful and made money, then we know we are on the right track, and the assurance of being right increases our confidence, and doubles our strength for future work.

Seed Corn. — So many requests have come to us from all parts of the country for *seed corn*, that we have placed a few bushels in the hands of *Messrs. Parker, Gannett & Osgood*, seedsmen, North Market street, this city, for distribution. Our friends can procure it of them. We do not know that it has any marked excellencies as a *variety*, but it is perfectly *sound* and *well matured*, and is reliable seed.

THE RELATIONS OF WATER TO AGRICULTURE.

[*Dr. Nichols's Address at Greenfield.*]

There is a property in water which is of the highest importance, as upon it all success in agriculture depends. I allude to its solvent power, or its capability of taking up and holding in solution every substance which enters into the constitution of plants. This singular property is, as it were, the pivot upon which the existence and welfare of the race is poised. Take away from water this power, and no greater disaster could result if the dynamical forces of the universe were thrown into disorder. The rain which falls upon the earth is due to the condensation of aqueous vapor previously existing in the atmosphere, and supplied in great measure from the surface of the sea, the area of the latter compared with that of the land being very great — necessarily so perhaps to furnish the requisite extent of evaporating surface. This water is, as is well known, perfectly fresh and pure, the saline constituents of the ocean having no sensible degree of volatility at the temperature at which the vapor has been raised. No sooner, however, does it reach the earth than its solvent powers are brought into requisition, and it becomes contaminated with, or takes up a large number of substances, which it holds in solution. The waters of rivers and springs invariably contain a greater or less amount of alkaline and earthy salts, which have been washed out of the earth by percolating rains. In the water we daily use for household purposes, and that which we furnish to our animals, are found considerable quantities of these salts, together with numerous other substances. We are accustomed to regard these as *impurities*, and they are such, strictly considered; but these very impurities are of vital consequence to the living system. These matters exercise an important influence upon the body in health and disease, and if they were entirely absent, physical weakness and probably death would ensue. It has been proved by careful experiments upon men and animals, that pure distilled water, so vapid and disagreeable to the taste, cannot be allowed to take the place of impure spring water, without producing emaciation and actual disease. There is a wonderful provision in nature by which the solvent powers of water are prevented from being injurious to the race. It will be understood that water is capable of dissolving many compounds of the elementary bodies which are poisonous or prejudicial in their influence, as well as those which are harmless or beneficial. Among the metals, almost the only one the oxide of which is harmless to the living body, is the metal iron. This is held in almost all natural waters. If the oxides of copper or lead were as constantly present in our springs, lakes and rivers, as iron, our earth would be uninhabitable. The daily absorption into the system of minute quantities of metallic poisons, is known to be followed by consequences of a fearful kind. Why are not these poisonous salts present in our natural waters? It is not owing to their insolubility, but to the fact that they are very sparingly diffused through the earth; they are not present in most soils. Iron is everywhere; copper, lead, arsenic, nickel, etc., are confined to specific localities, away from the great centres of population. Lime is a very abundant product of nature, and the water in some sections is changed with it, in the form generally of a carbonate. If another carbonate, — the carbonate of baryta, — were as common, animated life would fall before its deadly influence. Thus we see the hand of kind Providence manifested in all the provisions of nature. The condensation of poisonous substances held in water leads me to briefly remark upon the importance of not doing violence to ourselves, by allowing the deleterious metals which nature has so wisely placed in remote localities, to come in contact with water designed for culinary employment. This we are very liable to do, in the use of leaden service-pipes. I do not intend to create needless alarm, but I must be permitted to say that more of the obscure and painful diseases which come into the notice of physicians are due to lead-impregnated water, than is generally supposed. Many of these instances are found in the families of farmers, for unfortunately the innovations of fashion and modern improvements have led to the banishment of the old well-sweep and curb, and the copper pump and leaden service-pipe have taken their place. It should be understood by farmers and stock-raisers that it is not the members of the household alone that suffer from lead-impregnated water; the animals — the cows, the oxen, and the horses — are just as susceptible to its deadly influence as human beings. I have frequently found in my observations in the country, that the stock upon farms were furnished with water conveyed through lead pipes from lakes and mountain springs, while the family, with commendable caution, drew their supplies from other and safer sources. Many a fine animal has been lost to its owner through the agency of lead poison, and I trust the hint given will not pass unheeded. Iron pipes for the conveyance of water are cheap and safe under all possible conditions, and if those of the capacity of one or two inches are used, they will not soon become obstructed with rust. Never employ what is known as "galvanized" iron pipe, as it is exceedingly dangerous during the first two or three months of service. The superficial covering of zinc upon its surface is rapidly decomposed, and the carbonate and oxide are held in solution or suspension in the water. The salts are hurtful, and must not be allowed to mingle with the food and drink. I allude to this variety of pipe at this time, because I have recently been consulted in several cases of poisoning resulting from its use.

The vast importance of the solvent power of water will be appreciated when it is understood that it is due to this that all plant structures are able to grow. The aqueous fluid which slowly but constantly during the life of the plant creeps up from the roots, passing through every microscopic cell and fibre, carries along in its current the little atoms of inorganic substances which are so essential to its development. The stream floats not only a great variety of common and well-known elements and compounds, but also, in the case of many plants, some of the most rare and curious of which science has any knowledge. Potash, lime, nitrogen, phosphorus and silica, are almost universally found in the sap and substance of plants, and these are the elements which the farmer is desirous of placing in the soil so that the water may dissolve and convey them in ample abundance to vegetable structures. These are the great essentials so far as the supply is connected with the agency of water, and they are in a measure accessible; but there are other bodies of the highest importance which it is impossible to furnish. We can supply in a large measure the nitrogenous and other elements which are common to the cereal grains, but we cannot in the case of many of the esculent vegetables. It is certainly remarkable that the common garden beet demands from the water of its circulation one of the rarest of all the minerals, rubidium. This metal has only recently been made known to us, through the agency of that marvellous optical instrument, the spectroscope. When and how the water finds and takes up this strange metal, is a problem we are wholly unable to solve. By spectroscopic analysis we are able to detect the thirty-thousandth part of a grain of the chloride of the metal; yet it is so sparsely disseminated that even this delicate test fails to give any signs of its presence in soils upon which the beet-root flourishes. The growth of the root demands it, and water by some subtle instinct hunts it from the soil, and supplies it in the needed quantity. Tobacco is one of the most extraordinary plants which spring from the soil. In its ash are found a class of rare and complex bodies which it has abstracted therefrom, and which are not found in any other regular structure. Also, it is a great plunderer of the soil, in respect to those substances which are supplied to the soil through the ordinary fertilizing agents. The amount of mineral constituents which it carries off, can be judged of by carefully examining the ash upon the end of a smoker's cigar. Every one hundred pounds of the dried leaves which the soil produces, rob it of at least twenty pounds of its most valuable mineral atoms. This vast amount of mineral the plant pumps up, while held in solution in water. To this plant, potash is what pie or cake is to the school-boy: it evidently loves it, and consumes it in prodigious quantities. Five per cent of the dried leaves are composed of this alkali. A bushel of ashes, such as the smoker so carelessly and wastefully brushes from the end of his cigar, would, if leached, and the lye formed into soap, make enough to answer the purpose of a small family for a year. The new and rare element, lithium, is found in the tobacco plant, and, although the

spectroscope will detect in any substance a quantity so infinitesimally small as the six-millionth part of a grain, yet it is hardly revealed in soils in which the plant flourishes. These facts open up subjects of thought so interesting and instructive, that it is hazardous to enter upon their consideration in the few moments allowed to a public address. I have only drawn a brief outline of some of the important relations of water to agriculture. It is a subject of almost limitless extent, and may be studied with profit by every cultivator of the soil.

Boston Journal of Chemistry.
BOSTON, MARCH 1, 1870.

PROSPECTUS.

BOSTON Journal of Chemistry.

Vol V. — Commencing July 1, 1870.

Volume V. of the JOURNAL, commencing July 1, 1870, will be increased in size, each number containing not less than *twelve pages* of reading matter. It will be printed from stereotype plates, on the finest book-paper; and we shall continue to make it the *best and cheapest scientific journal in the world. The terms for the* JOURNAL *will be one dollar per year; single numbers, ten cents.*

The JOURNAL will be, as it has been, independent, unbiased, careful, and reliable. No individual, corporation, or organization is rich or influential enough to suppress its opinions, or in any way control its influence. It will continue to expose frauds, schemes, and speculations, which profess to originate in or grow out of progress in science and art. The great and growing evil of *adulterations* in articles of food, medicine, fertilizers, and substances used in the arts, will receive special attention, and the nature of the sophistications and adulterations will be fully exposed. We shall present numerous useful practical formulæ, recipes, and scientific suggestions, which alone will be worth many times the price of the publication.

TO PHYSICIANS,

It will continue to be of *special service*, as it will keep them informed of the nature of all new remedial agents, all new discoveries in chemical and medical science, all new principles or processes connected with toxicology and pharmacy.

TO DRUGGISTS,

It will come as a reliable friend and adviser, affording information and instruction upon all matters relating to the manufacture and dispensing of medicines, and the other substances and agents produced or vended by them.

TO FARMERS,

It will impart information upon the important subjects of the chemistry of plant-growths, and the nature and preparation of fertilizing agents.

TO CHEMISTS, MANUFACTURERS, ARTISTS, TEACHERS, STUDENTS, CLERGYMEN,

All intelligent readers, men and women, everywhere, the *Boston Journal of Chemistry* will supply information and instruction of the highest importance and value.

The JOURNAL has, at the present time, a large army of friends, and these we ask to aid us in extending its circulation. Our patrons know how instructive and useful it *has been* in the past: we assure them it will be even *better* in the future. Cannot each one send us a new subscriber, to commence with Vol. V.?

We make this offer to *new subscribers:* All those who subscribe, and send us *one dollar* in advance, will receive the remaining numbers of Vol. IV. They will receive the whole of Vol. V., and all the numbers of Vol. IV. which are issued after the date of their subscription. *Subscribe early*, and thus obtain a part of Vol. IV. as a gratuity.

JAS. R. NICHOLS & CO., Publishers,
BOSTON.

THE JOURNAL GIVEN AWAY.

ON receipt of the publisher's price of any one of the following periodicals, we will send *both the* JOURNAL *and that periodical* for one year. This offer applies to those persons only who are not already subscribers to either.

EVERY SATURDAY	$5.00
ECLECTIC	5.00
NATION	5.00
N. Y. JOURNAL OF PSYCHOLOGY	5.00
PHILA. MEDICAL AND SURGICAL REPORTER	5.00
PUTNAM'S MAGAZINE	5.00
AMERICAN NATURALIST	4.00
APPLETON'S JOURNAL	4.00
ATLANTIC	4.00
COLLEGE COURANT *(New Haven)*	4.00
GALAXY	4.00
HARPER'S MONTHLY, WEEKLY, OR BAZAR *(each)*	4.00
LIPPINCOTT'S MAGAZINE	4.00
N. Y. MEDICAL JOURNAL	4.00
OLD AND NEW	4.00
SUNDAY MAGAZINE	3.50
HOURS AT HOME	3.00
TILTON'S HORTICULTURAL MAGAZINE	3.00
GOOD WORDS	2.75
GOOD WORDS FOR THE YOUNG	2.50
OUR YOUNG FOLKS	2.50
OLIVER OPTIC'S MAGAZINE	2.50
RIVERSIDE	2.50

ERRORS IN CHEMICAL NAMES.

"SULPHATE of copperas" was given in a newspaper, the other day, as one of the components of a recipe. Did it mean sulphate of *copper*, commonly known as "blue vitriol," or did it mean *copperas*, often called "green vitriol," which is a sulphate of *iron?* Copperas contains no copper, though its name is suggestive of that metal. In the recipe to which we have referred, a chemist would suppose that sulphate of copper was intended, and not copperas; but if one should go to a druggist's and ask for "sulphate of copperas," a careless clerk would be quite as likely to give him the one as the other.

It is no uncommon thing to see these slips of the type in recipes published in the newspapers. We have seen "organized ether" for "ozonized ether," in a city journal. "Carbolic acid" has been printed as "carbonic acid" in repeated instances. Now a misprint in itself is no unpardonable sin, but misprints of this particular kind are *not* so readily to be excused. They are especially liable to escape detection, and they may do a deal of mischief. We can imagine cases in which the consequences might be very serious, and even fatal. Ought journalists, then, to attempt to print such matter, unless some one connected with the periodical is sufficiently versed in science to know whether it is printed correctly? Caution is certainly demanded in the use of chemical names, when we know that, if changed in a single letter, they may represent substances of radically different properties. A *sulphate* and a *sulphite*, or a *sulphite* and a *sulphide*, are almost identical as mere words, but the compounds known by those names are wholly dissimilar in their nature, and it might be dangerous sometimes to mistake one for another. There are hundreds of such nearly coincident terms in the chemical nomenclature, readily distinguishable by one who is familiar with the principles of that nomenclature, but easily confounded by one who does not understand the system.

Sometimes these blunders are simply amusing. A harmless joke perpetrated by a scientific writer may be taken in sober earnest by one of these editors who dabble in things above their comprehension, and may thus become, for those who "see it," a better joke than it was in the first place. In a letter sent to the London *Times*, not long ago, Mr. Crookes referred to the highly explosive nature of a dye which had been denounced as poisonous. He said: "It is almost as explosive as nitro-glycerine, and has already destroyed one factory, with loss of several lives. Should the dye retain this character in the fabric, the wearers of these socks would be able to vary in a highly sensational manner the excitement they are now indulging in." The editor of another London paper, delightfully innocent of all appreciation of the joke, reproduced the statement in the following shape: "Mr. Crookes has recently asserted that woollen stockings dyed with picrate of potash are liable to explode on the feet of those who sit too near the fire." This was sufficiently startling, and probably no ambitious cockney who had bought a pair of the brilliant but dangerous stockings, ventured to put them on after reading it. The double risk of being poisoned or blown up would be too much for John Bull, though a Yankee might be reckless enough to run it.

GEORGE PEABODY.

SINCE the last issue of the JOURNAL, the world's great benefactor, the friend of education, science, art, and everything that tends to elevate and ennoble the race, has been gathered to his final resting-place. George Peabody sleeps by the side of his father and mother, in the cemetery of his native town, Danvers. No private citizen ever received, at his decease, higher honors, and no one ever more richly deserved them. But our readers are acquainted with all the details of what has occurred, and therefore we need not dwell upon the subject. In this connection, however, we are reminded of a remark made by Mr. Peabody, the last evening we spent with him. It seemed to express a presentiment that the time of his departure was not far off. He was speaking of his residence in Baltimore, and giving some most interesting reminiscences of those with whom he was connected in business. "But," said he, "they have nearly all passed away, and the time is short for us all. I have in my trunk a document which I carry with me wherever I go. It contains the names of *one hundred and twenty* of the prominent shippers and merchants of Baltimore, who were in business when I was there, and as fast as I have learned of their *failure in business, or death*, I have noted it against their names. The last record left *but six names unmarked*. Most of them are *dead*, and a large proportion failed in business before death."

The examination of this document seemed to fill him with the profoundest impressions of the mutability of all earthly things, and the uncertainty of life. The paper had originally been placed in his hands by the merchants, as chairman of a committee, chosen to present a petition to the board of underwriters.

Among the many institutions aided or founded by Mr. Peabody, we think no one will longer perpetuate his *memory*, or render more efficient aid to science, than the Peabody Academy of Science, at Salem. We shall give some particulars regarding this institution at a future time.

Mr. Carl Meinerth, of Newburyport, has furnished us a few dozen very beautiful mezzotint card photographs of Mr. Peabody. We will send one of them to any subscriber who will send us the name of a new subscriber for Vol. V., with one dollar enclosed.

☞ Every number of the JOURNAL is stereotyped, and therefore we can furnish back numbers of the present volume to all who may desire them.

CHLORAL. — The editor of the JOURNAL, having been recently prostrated by great nervous exhaustion, resulting from protracted mental labor, made trial of the new agent chloral hydrate as an hypnotic. It proved, in his case, a remedy of remarkable efficacy. After suffering from nervous wakefulness for a period of nearly seventy hours, thirty grains of chloral brought in thirty minutes a sweet refreshing sleep, lasting eight hours. In three subsequent trials it has acted as a powerful, harmless hypnotic. He is still too weak to make any extended observations regarding the remedy, but desires, in this number, simply to call the notice of physicians to an agent which is certainly worthy their prompt attention.

ANCIENT STATES AND EMPIRES. — A notice of Dr. Lord's new book, *Ancient States and Empires*, will be found under its appropriate head. We have spent so many pleasant hours in its perusal, and have derived from it so much instruction, that we feel a strong desire that our readers should have access to the work. To bring it within the reach of those who have not the means to make a direct purchase, we propose to send the book free to any one who will send us *ten dollars*, with the names of *ten new subscribers*. We will enter the names of the subscribers for the whole of Vol. V., and send them all the remaining numbers of Vol. IV. This liberal offer ought to place the history in at least a thousand families, where it would not otherwise find its way. The price of the work is $3.00.

ONE OF THE DRUG STORES. — A prominent drug store, situated on the corner of two important streets in this city, is advertised in the newspapers as for sale. The owner says: "A knowledge of the drug business is not necessary, as the trade is principally fancy goods, patent medicines, cigars, and soda water."

In what strange association medicines for the sick are placed in this and other cities! "*Patent medicines, fancy goods, cigars, and soda water*" are principally sold in this "*drug store*," and no knowledge of medicines is needed by the proprietor! And yet this *is* a drug store, and the sick are expected to go to it for remedies. The proprietor deals in cigars and soda water, needs no knowledge of medicine or pharmacy, and yet has medicines to dispense. What a commentary this is on the present state of the drug trade!

EDITORIAL NOTES.

A REMEDY FOR THE HEADACHE. — "We can confidently recommend" to those suffering from headache the following excellent recipe, which is given by Pliny: "The small bone from the head of a snail that has been found between two cart ruts, and after being passed through a gold ring with a piece of ivory, is attached to the patient in a piece of dog's skin." The eminent old Roman adds that it is "a remedy well known to most persons, and always used with success"; but if, owing to constitutional peculiarities of the patient, it *should* fail in any case, we advise following it up with another valuable prescription from the same distinguished philosopher, namely, "the brains of a vulture mixed with oil and cedar resin, and applied to the head and nostrils."

SOME GOOD THINGS IN ANCIENT ROME. — But the Romans were not the worst of fools after all. Somebody has lately shown that the water supply of the ancient metropolis was more liberal than any great city of our day has provided for its inhabitants. The public baths were not inferior to those of Boston; in fact, they were on a considerably larger scale, and were patronized by all classes of the people. There were also some good sanitary regulations, and, what is more, they were enforced in the sturdy Roman way. Overseers, appointed by the government, examined the meat in public markets, and butchers were often fined for selling that which had not been officially approved. The record of some of the prosecutions under this law has been preserved to our day. There were no enactments against the sale of bad kerosene, for the excellent reason that the poor benighted heathen of that day had no kerosene, good or bad; but we may be sure that if they *had* had it, and if, as in the city of New York, more than one-tenth of all the fires (98 out of 913 in a year) had been caused by it, there would have been stringent laws to regulate its storage and sale, and those laws would not have been a dead letter.

"THE WORLD OF WONDERS." — An English book with this title is a fair sample of a certain class of popular books on science, being a jumble of facts and falsehoods gathered at random by an ignorant editor. Among the "wonders of digestion," a mournful story is told of a juggler who passed a sword "too far down the *windpipe*" into his stomach, where it was nearly all dissolved, but "a foolish medical man ordered the conjurer horse exercise," which led to "a severe internal wound and death." We hope the doctor was indicted for malpractice, and that no physician will ever again be in haste to prescribe horseback riding for a patient who has swallowed a sword. The same book, among "wonders of vegetation," gives pictures of a turnip with a human face (grown in 1682), a radish in the form of a human hand (A. D. 1672), and other plants equally remarkable.

Our readers must not confound this "wonderful" book with the "Library of Wonders" published by Scribner & Co., of New York. All the books of that series are thoroughly trustworthy.

SAL MIRABILE. — Speaking of wonders reminds us of Glauber and his "wonderful salt," or *sal mirabile*, as he named it, because it had, according to his view, wonderful power in the vegetable world, in medicine, and, indeed, for "all men of whatsoever state or condition." He little thought that hundreds of thousands of tons of it would come to be made yearly, not for direct use, but simply as a stage in the manufacture of soda-ash, which is mainly used in the preparation of that *sal mirabile* known as *soap;* for soap, chemically speaking, *is* a salt.

POPULAR SCIENCE. — As a recent writer has well said, "Do not let us suppose that popular knowledge is merely a little of the least valuable. The people seize on the highest, and, for general purposes, best; and let scientific men blame themselves in most cases if their work is not known to the public. The amount of scientific work done in Europe is beyond the ken of any man. Even profound scientific men are obliged to pick out the best in a popular way; the word *popular* having a meaning differing according to the man. Scientific journals exist professedly to abstract the best, and reviews and newspapers abstract again, and make clear; that which bears explanation without long study becomes popular. No magnitude repels the public; vastness is always attractive, but complicated studies require time, and these never can become popular, whether small or great in value. The people seize *the best they can use*, and this is popular science."

NEW SOURCE OF QUICKSILVER. — A stratum of quicksilver ore has been recently discovered in the island of Borneo. The ore promises to be one of the richest in the world, yielding from 70 to 80 per cent of pure metal. In fact it is very nearly pure mercuric sulphide. The average yield of mercury ores is from 2 to 20 per cent of metal. Borneo is rich in minerals of all kinds, and the ores are generally of superior quality.

FAST TRAVELLING. — There is a canal from Mons in Belgium to Paris, a distance of 350 kilometres, or about 220 miles. The barges laden with coal that navigate this canal make only three voyages during a whole year. The statement is made on the authority of *Les Mondes*, and may, therefore, be depended upon.

COAL-TAR COLORS. — 100 lbs. of coal-tar yield 3 lbs. of crude, and 1½ lbs. of pure benzol. From this are obtained 3 lbs of nitrobenzol, 2.25 lbs. of rosaniline, 3.37 lbs. of aniline red, and 1.12 lbs. of fuchsine; 1 lb. of pure fuchsine requires 3000 lbs. of pit-coal. The coal-tar produced by all the gas-works in Europe is sufficient to yield annually 53,000 cwt. of fuchsine!

MARVELS OF TELEGRAPHY. — Somewhere in the *Spectator* Addison quotes, from a monkish Latin writer of the middle ages, an account of a wonderful magnet, by means of which two lovers, far away from each other, might, under certain conditions and at certain hours of the day, hold sweet converse, in spite of the leagues that separated them. This dream of the mediæval monk has become a reality under the magic wand of modern science; or rather, the fiction has been more than made true. At all hours of day and night, across broad continents, beneath thousands of miles of tempestuous ocean, messages are sent on the wings of lightning. All things that are done by men are made known throughout the circuit of the globe in less than the "forty minutes" in which Puck promised to put a girdle round it. The miracle has become so familiar to us, that it ceases to excite our wonder or admiration; but what would old Ben Franklin say, if he could come back to earth and pay a visit to one of our telegraph offices?

THE AMERICAN DISEASE. — A Yankee, writing home from Berlin, says that dyspepsia, neuralgia, and nervous exhaustion are much less frequent in Germany than here at home; and that a friend of his who consulted a German physician was told that he had "the American disease, — dyspepsia."

WESTWARD MARCH OF MEDICAL LITERATURE. — A medical journal has been started in Oregon, under the title of the *Oregon Medical and Surgical Reporter*. It is edited by Prof. E. R. Fiske, of the Faculty of Willamette University, in the city of Salem, and published at $4.00 per annum. Success to our new contemporary on the sunset edge of the Continent!

CONCERNING DROPS. — Herr Quincke, of Berlin, has found that the size of drops bears a fixed relation to the chemical composition of the liquid. He has proved experimentally that all liquids, at a temperature near their liquefying point, have specific cohesions, which are proportionate to the numbers 1, 2, 3, 4, etc. Taking the specific cohesion of the metallic bromides and iodides as 1, that of mercury, the nitrates, the metallic chlorides, the sugars, and the fats, will be 2; that of water, the carbonates, the sulphates, and probably also the phosphates, will be 4. In the case of the metals (referred to the same standard), the specific cohesion of lead, bismuth, and antimony is 2; that of platinum, gold, silver, cadmium, tin, and copper, is 4; that of zinc, iron, and palladium, 6; that of sodium, 12.

DON'T USE CRACKED DISHES. — Such dishes absorb oils and fats from the various kinds of food put into

them. These fats soon become decomposed in the pores of the dish, and no amount of cleansing can remove the nauseating and poisonous deposit. The peculiarly unpleasant taste sometimes noticed in pie-crust is caused by baking it upon old cracked dishes, from which it absorbs the rancid fat left by former bakings.

ANTIDOTE TO CARBOLIC ACID. — Until people learn to distinguish the different preparations, of greatly varying strength, which pass under the common name of *carbolic acid*, it will be well for them to make a note of the following suggestion published in England by one of the leading houses engaged in the manufacture of this important article: —

"Messrs. Calvert wish to make known the fact that sweet oil or castor oil in large quantity is the best antidote to carbolic acid, when it has been swallowed in poisonous doses."

Speaking of poisons, somebody has recommended that the labels of druggists' bottles in which poisons are put up, should bear a brief statement of the best antidotes for those poisons. It is a good idea, and if carried out would often be the means of saving life.

HORSE-CARS WITHOUT HORSES. — A company has been organized in New Orleans, for the application of condensed air as a motive power for street railways. For economy in weight, the cylinders into which the air is compressed are to be made of *paper*. A trial cylinder of this kind has borne a pressure of three hundred pounds to the square inch without yielding. A car fitted up for experimental purposes, with leaky iron cylinders (weighing 1600 pounds) made three miles and a half in seven and a quarter minutes, carrying twenty-eight passengers. The cylinders are to be on the top of the car, and are to be charged at the depot by means of a stationary steam-engine.

A NEW USE OF PHOTOGRAPHY. — A London company is building a railway somewhere in South America, and photographs of the completed portions of the road have to be sent to London as vouchers for the work done by the contractors, before they can receive the successive instalments of their pay.

A BIG FIRE. — The heat given out from each *square yard* of the sun's surface is as great as would be produced by burning *six tons of coal* on it *each hour*. Taking the sun's surface as 2,284,000,000 square miles, each of which contains 3,097,600 square yards, our young friends can figure up how many tons of coal it would take to supply this big heating apparatus. All the coal fields of our little planet would be exhausted in very brief space, if they had to feed a furnace like that.

☞ It is very gratifying to know that the proposition to increase the size and price of the JOURNAL, meets with nearly the unanimous approval of our old friends and patrons. So strongly attached are they to the publication, and so much practical instruction have they derived from it, that even if the cost was many times as great, they would not allow its visits to be discontinued. In publishing a journal of this character for four years at a cost barely sufficient to pay for paper and printing, we have done what we think was never accomplished before. Although no pecuniary return has come to us, we have the satisfaction of knowing that an army of friends has been raised up, all over the country and the world, who will remain with us to the end. This journal has but just entered upon its career of usefulness, and we can assure old friends and new, that we have an abundance of good things in store for them.

LITERARY NOTES.

Scribner & Co., of New York, have just published *Ancient States and Empires*, by John Lord, LL. D. Our readers will remember our commendation of Dr. Lord's *Old Roman World*, which appeared two years since. This new book is even more attractive and interesting. It begins with the history of mankind in the Garden of Eden, and carries the reader along the great succession of events to the fall of the Roman empire. The work should find a place in every family, for its perusal will delight and instruct children as well as adults. Dr. Moffat, the accomplished Professor of History in Princeton College, pays it the following appropriate tribute in the *Princeton Review*:—

"This book is not a mere compendium of history or sketches, or dry and dead annals. It has, like all the author's productions, the flesh and blood hues, the motion, the breath, and pulsations of life. It is full of graphic portraitures of the life, manners, customs, and institutions of the Ancients, and of the growth of Oriental, Greek, and Roman culture and civilization. There are few who have not known and felt the inspiration of the author's enthusiasm, poetic eloquence, and vivid delineations in his great historic lectures. They will find all these animating the printed page. They will also find the condensation and clearness required in a text-book for the young, enlivened with all the brilliancy of which the matter and space admit. We think that it is highly adapted to the use of students in schools and colleges, and of all who. before going into thorough historical research, wish a pleasant introduction to the elements of ancient history."

Prof. Pumpelly's *Across America and Asia* has reached a third edition before it is three months old. This rapid sale of a book which, as one of the best critics has said, "repels at first sight," is simply a tribute to its substantial merit. *Old and New* (the new magazine of that name which, by the way, is old and new in leaping at once into mature life, like Minerva from the brain of Jove), says of it: "Whoever reads five pages will not leave the book willingly. His excellent opportunities were well improved by the author; and he has made a fascinating narrative, which carries with it sound and sagacious observation of the great social problem the East now presents to the West. His sincerity impresses us at once, and he has given that bird's-eye view which is the most reliable in this hurried and partial intercourse between modern nations. Who is ever deceived when he follows his first impression of a human face or character? It is only when this subtle image is blurred and confused by subsequent and imperfect knowledge, that the deep instinct which attracts or repels the natures of men or peoples, is turned away from its true course."

While this book will attract the general reader, it will have a special interest for the scientific student. The author is one of the few travellers who know what to see, and how to see, and he knows, also, how to tell the story of his travels in a clear, direct, graphic way; so that he gives us as complete an account of the physical geography (using the term in its widest sense) of the regions he visited as could well be put into the space.

Fields, Osgood, & Co. have reprinted *A Physician's Problems*, by Dr. Chas. Elam, — a thoughtful and able book on a most fascinating subject. The topics are those which relate to the "brotherhood of spirit and body," and, as a brother critic has said, the author "has treated them with the learning of a scholar, and the practical sense of a trained medical man. It is a volume which we read with decided zest, for its discussions have a sort of personal interest; and besides, the reader is constantly refreshed by anecdotes, instances, references to literary men and the habits of great men, by whatever, in short, will throw light upon the problems considered."

The editor of *Old and New* gives a list of twenty-one books which have recently been most in demand "at the largest retail store in Boston," and among them are the three noticed above — Dr. Lord's, Prof. Pumpelly's, and Dr. Elam's. The fact is creditable to the readers as well as to the writers.

We referred in our last to the fact that the popular magazines are making *science* one of their prominent features. This is the case with *Old and New*, which has secured Profs. Cooke and Lovering, of Harvard College, among its contributors in this department.

Putnam's Magazine, which is hereafter to be under the editorship of Parke Godwin, puts down as one of its "distinctive features," and *first* in the list, "popular papers on science and natural history, and practical information for everyday life."

Lippincott's Magazine, which has won a high literary reputation in its first two years, promises a continuance of its excellent "articles on popular science," among the other temptations of its prospectus.

Lippincott & Co. have just added *Good Words*, one of the most successful of the English popular monthlies, to their list. Their edition is a fac-simile of the original, and we have no doubt that it will become a favorite on this side of the Atlantic. Charles Kingsley and Prof. Ansted are among its scientific contributors.

Carlyle has said that "history is distilled newspapers," and the *Half-Yearly Abstract of Medical Sciences*, edited by Dr. Stone, might be called "distilled medical journals." Sixty or more foreign periodicals are boiled down, and their essence given in these semi-annual volumes of three hundred pages each. The one for the last half of 1869 has just been issued by Henry C. Lea, of Philadelphia, and shows the same judgment and skill in the selection and condensation of matter as its predecessors.

The *College Courant* (New Haven, Conn.), is not a mere organ of Yale College, but represents the collegiate interests of the whole country. It numbers among its contributors more than a hundred presidents and professors of our leading colleges. We can indorse the opinion expressed by Dr. Dunster, in the *New York Medical Journal*, that "it is one of the most interesting and valuable of our non-professional exchanges," and "indispensable to all college graduates of this country."

Every Saturday, in its new form, takes the leading place among our illustrated papers, while it gives, as it always has done, the very cream of foreign periodical literature of the lighter sort.

Medicine.

HYDRATE OF CHLORAL.

THE distinguished Dr. W. A. Hammond publishes in the *New York Medical Journal* the following interesting and important article upon chloral. Although it is long, we feel assured our readers will thank us for placing it before them:—

All the experiments which have been performed with the hydrate of chloral, whether upon man or the lower animals, go to show that it is a powerful hypnotic; but there is a difference as to whether the first effect is not the very reverse of sedative. Demarquay has shown, by *post-mortem* examinations, that it produces congestion of the brain and its membranes; but his researches are, in this respect at least, not very precise, for they do no

touch upon the point of different effects being produced by different doses; nor was any accurate examination of the state of the cerebral circulation made during life. My first object, therefore, was to determine the influence of the hydrate of chloral over the cerebral circulation.

Experiment.—I examined very carefully, with the ophthalmoscope, the retinæ of a rabbit, and ascertained that they were in a normal condition. I then injected seven grains of the hydrate of chloral, dissolved in water, into the cellular tissue, and two minutes afterward made another ophthalmoscopic examination. The vessels were decidedly increased in size, and several that were previously invisible made their appearance. The pulse and respirations were both increased in frequency. At the end of five minutes another retinal examination showed increased congestion, not only of the retinæ, but of the optic disks. The pupils were largely dilated. After seven minutes had elapsed, the animal exhibited signs of drowsiness. The pupils began to contract; and examination with the ophthalmoscope showed that the retinal congestion was greatly lessened. At the end of ten minutes sleep was profound. The pupils were strongly contracted; the temperature had fallen four degrees; the action of the heart was less frequent; the respirations were diminished, and the retinæ were of a pale pink color, with but two or three very minute veins visible. At the end of two hours the sleep was very deep; the respirations were feeble and slow; the ears were cold, and the retinæ were pale and exsanguined. After nine hours and twenty minutes the animal was found awake, and in a perfectly normal condition as regards temperature, circulation, respiration, and the condition of the retinæ.

This experiment was repeated three times, and always with similar results.

Now, as is well known, the ophthalmoscopical examination of the retinæ affords very exact indications as to the condition of the cerebral circulation; but by means of an instrument devised, though in somewhat different forms, by Dr. Weir Mitchell and myself, independently of each other, we are enabled to determine the point directly. This instrument, which I venture to call the cephalo-hæmometer, consists of a brass tube which is screwed into an opening made in the skull with a trephine. The lower end of the tube, which rests upon the dura mater, is closed with a piece of very thin india-rubber cloth; the upper end of the tube is closed with a brass cap, into which a glass tube is inserted. To this tube a scale is attached, and the brass tube is filled with colored water, so that when it is screwed into the skull, and the end touches the dura mater, the level of the liquid stands at zero. When the apparatus is in place and properly adjusted, it is very evident that any increase in the amount of blood circulating through the brain will cause the dura mater to press with increased force against the rubber membrane, and will thus cause the liquid to rise in the glass tube. Any diminution of the circulating fluid will cause the level of the liquid to fall. We have thus a very accurate means of measuring the cerebral hæmostatic pressure.

Experiment.—I operated on a rabbit with a small trephine, and inserted a cephalo-hæmometer. As soon as the instrument was *in situ*, I injected seven grains of the hydrate of chloral into the cellular tissue. In one minute and ten seconds the fluid began to rise in the tube, and in three minutes it stood at a point an inch higher than the normal level. After five minutes it was an inch and seven-eighths higher. This was the maximum point. It now began to fall steadily, and in two minutes and fifteen seconds reached the zero, the point from which it had started. Coincident with its further depression, drowsiness came on, until, when the level was about an inch below the zero, the condition of sleep was well established. The fluid continued to fall till the level was two inches and a half below the zero, which point was reached in thirty-two minutes after the injection was made. It remained stationary about an hour longer, and then fell about a quarter of an inch lower. It was not further depressed. After the lapse of seven hours and forty minutes it began to rise, and with this change the respiration, which had been feeble, became stronger and more rapid, and the animal exhibited signs of returning animation. At the end of nine hours and twenty minutes the animal awoke, and the level of the liquid, which at the time was about half an inch below the zero, rose rapidly to the original point. It continued to rise for a few minutes, but gradually fell again to the zero. This experiment was repeated upon three other rabbits, and similar results elicited.

Up to this time, it will be observed, that what may be called large doses for rabbits had been employed. Desirous of ascertaining the effects of a small dose, I performed the following experiment:—

Experiment.—Having adjusted the cephalo-hæmometer to the skull of a large rabbit, I injected under the skin a solution containing one grain of the hydrate of chloral. The water in the tube began to rise in a minute and forty seconds, and at the end of five minutes was three-eighths of an inch above the zero. The animal continued lively, and the pupils were dilated. The respiration and pulse were both accelerated. In half an hour the level of the liquid was at its highest—about three-quarters of an inch above the starting point. It now began to fall slowly, and in fourteen minutes was at the zero. During the whole time of the experiment the animal showed no signs of sleep, but was, on the contrary, unusually active. Ophthalmoscopic examination revealed the existence of a state of congestion of the retinæ, which lasted till the liquid in the cephalo-hæmometer had fallen to its original point. The experiment was repeated, with similar results, on two other rabbits.

Demarquay found, as one of the results of his investigations, that the hydrate of chloral in large doses produced continued congestion of the cerebral blood-vessels of the rabbits to which he administered it. His observations were made *post mortem*, and cannot, therefore, be considered as altogether reliable. The congestion was, in all probability, caused after death.

To be still further assured upon the point, I performed the following experiment:

Experiment.—I removed from a large rabbit nearly one-half of the cranium, and, opening the dura mater, laid bare the cerebrum and its membranes. I had thus almost the whole superior and external surface of one hemisphere exposed to view. I now injected one grain of chloral into the cellular tissue. In about two minutes the surface became redder and the vessels larger. I now injected five grains. The surface of the brain now became of a dark-blue color, and protruded through the opening in the skull. In something less than five minutes, however, a change ensued. The color gradually changed to red, the brain sunk again below the surface of the opening, and a state of anæmia ensued. With these changes the animal fell asleep. At the end of half an hour the surface of the brain was colorless, and no blood-vessel could be perceived. After seven hours and thirty-three minutes from the first injection, the brain again assumed a pale-red color, and the animal awoke.

I regard these experiments as showing conclusively that the first effect of the hydrate of chloral is to cause congestion of the cerebral blood-vessels, and that subsequently it induced directly the opposite condition. With a small dose, this latter effect is not reached, congestion only being produced.

[*To be continued.*]

A REMEDY FOR ASTHMA.

Editor Boston Journal of Chemistry:

For the benefit of those afflicted with *asthma*, I enclose a recipe which can be commended as being at least simple, safe, and useful. A prominent professor in one of our New England colleges, who has been an asthmatic for upwards of forty years, and tried a great variety of remedies, gives this the preference over all others. It consists simply in inhaling the smoke of stramonium leaves, which have been immersed in a saturated solution of nitre (nitrate of potassa), and then dried. Prepared in this way, it burns with great energy and completeness, rarely going out until the whole is consumed. These remedies, separately, have long been known, both to professional and private experience; but the combination seems particularly convenient and useful. It is best kept in a tin or other metallic box, the inside of the cover being used as a surface on which to burn it while inhaling. The effects are the more marked if it is used early, and before the paroxysm becomes fully developed. E. K. BAXTER, M. D.

Sharon, Vt.

Dr. R. Snead, of Strawberry Plain, Tenn., sends us the following:—

INGROWING TOE NAIL.—This painful abnormal condition of the toe-nail may be cured by allowing the nail to continue to grow without paring it. The boot or shoe will depress the nail at the *end* as it grows longer, which will gradually elevate it at the *point*, where it presses upon and into the soft tissues of the toe; thus removing the irritation, the sore soon heals. This is far preferable to the rash and painful operation of tearing off the toe-nail with forceps.

OINTMENT FOR CHILBLAINS.—(KAPELER).

℞ Almond Oil,	℥i.
White Wax,	℥iiss.
Spermaceti,	℥i.
Peruvian Balsam,	℥ss.
Muriatic Acid,	℥ss to i.

HARVARD UNIVERSITY.

Medical Department, - Boston, Mass.

SUMMER SESSION, 1870.

THE regular course of Summer Instruction will begin at the Massachusetts Medical College, North Grove street, Boston, on March 14th, and continue until the next Winter Course of Lectures, on the first Wednesday in November. The Session is divided into two Terms by the Summer vacation of two months. Gentlemen who finish their undergraduate course during the summer months, should join the Medical School at the beginning of the Fall Term, Sept. 13th, their requisite three years of study being thus completed in time for the special examination for medical degrees, which precedes the annual commencement at Cambridge.

Recitations are held daily by the Professors and Instructors in all the branches necessary to a medical education. Clinical instruction in Medicine and Surgery is also given daily at the Massachusetts General Hospital and the City Hospital. Other hospitals, and the various dispensaries and infirmaries in the city are likewise open to students. Lectures on special branches will be given at the College by University Lecturers, and courses on the sciences connected with Medicine, Zoölogy, Botany, Chemistry and Physics, will be delivered in Cambridge by the Professors in these departments, which students may attend without extra charge.

THE CHEMICAL LABORATORY is open during the summer, and practical instruction is given in physiological, pathological and toxicological Chemistry. A Laboratory is also opened in which students are thoroughly exercised in the management of the Microscope.

THE DISSECTING ROOM is open and abundantly supplied with RECENT SUBJECTS, during March, April and October. *No charge is made for anatomical material, or for demonstration.*

Fees.—The fee for instruction during the Summer Session, from March to November, is $100; for the Winter Lectures, $121. The fee for the entire year, for the Winter Lectures, as well as for the Summer Session, is $200. The fee for Graduation is $30. The fee for Matriculation is $5. This is appropriated to the increase of the Library, and is to be paid to the Dean once by all who desire to become members of the College.

FACULTY OF MEDICINE.

CHARLES W. ELIOT, LL.D., President.

JOHN B. S. JACKSON, M. D., Shattuck Professor of Morbid Anatomy, and Curator of the Anatomical Museum.
OLIVER WENDELL HOLMES, M. D., Parkman Professor of Anatomy and Physiology.
GEORGE C. SHATTUCK, M. D., Hersey Professor of the Theory and Practice of Physic.
JEFFRIES WYMAN, M. D., Professor of Comparative Anatomy and Physiology.
HENRY J. BIGELOW, M. D., Professor of Surgery and Clinical Surgery.
JOHN BACON, M. D., University Professor of Chemistry.
CHARLES E. BUCKINGHAM, M. D., Professor of Obstetrics and Medical Jurisprudence.
EDWARD H. CLARKE, M. D., Professor of Materia Medica.
CALVIN ELLIS, M. D., Jackson Professor of Clinical Medicine.
RICHARD M. HODGES, M. D., Adjunct Professor of Surgery and Clinical Surgery.
JAMES C. WHITE, M. D., Adjunct Professor of Chemistry, and Lecturer on Diseases of the Skin.
DAVID W. CHEEVER, M. D., Adjunct Professor of Clinical Surgery.
JOSIAH STICKNEY LOMBARD, M. D., Assistant Professor of Physiology.
JOHN E. TYLER, M. D., University Lecturer on Psychological Medicine.
FRANCIS MINOT, M. D., Instructor in Theory and Practice.
FITCH E. OLIVER, M. D., Instructor in Materia Medica.
HENRY W. WILLIAMS, M. D., University Lecturer on Ophthalmology.
JOHN P. REYNOLDS, M. D., Instructor in Obstetrics and Medical Jurisprudence.
J. NELSON BORLAND, M. D., Instructor in Clinical Medicine.
GUSTAVUS HAY, M. D., University Lecturer on Ophthalmology.
HENRY K. OLIVER, M. D., University Lecturer on Laryngoscopy.
J. ORNE GREEN, M. D., University Lecturer on Otology.
CHARLES B. PORTER, M. D., Demonstrator of Anatomy.
HENRY H. A. BEACH, M. D., Ass't Demonstrator of Anatomy.

☞ A detailed account of the Winter and Summer Sessions, as well as of the Harvard Dental School, will be forwarded (post-paid) by DAVID CLAPP & SON, 334 Washington street, Boston. The Janitor of the College will advise students in the selection of boarding places, and will always have a list of such as are in the vicinity of the College Building, varying in their rate of charges. Students are invited, on coming to town, to call upon the Dean of the Faculty, 114 Boylston street, to whom all letters must be addressed.

CALVIN ELLIS, M. D.,
Dean of the Faculty.

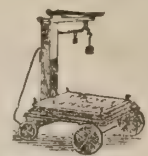
BOERICKE & TAFEL,

Homœopathic Pharmaceutists and Publishers,

145 Grand St., between Broadway and Elm St.,

Have constantly on hand a full assortment of Homœopathic Medicines and books for Physicians and family use. Medicines sold by whole sets or single vials.
Orders by mail promptly attended to.

FAIRBANKS' PREMIUM STANDARD



Scales.

These celebrated scales have now been justly acknowledged the Standard for FORTY YEARS, for ACCURACY, DURABILITY AND SUPERIOR EXCELLENCE in every respect, and they are constantly receiving such REAL IMPROVEMENTS as are suggested by the large experience and skill of the original inventor and manufacturers.

Every Variety, as

HAY, COAL, RAILROAD,

Butchers', Grocers', Druggists',

APOTHECARIES' and CHEMISTS' SCALES, &c., &c.

—ALSO,—

Patent Alarm Double Lock

AND

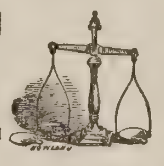
DIAL MONEY DRAWERS,

A PERFECT

PROTECTION

against

Till Tapping.



NEW ENGLAND WAREHOUSE,

118 Milk Street, - - - - BOSTON.

FIRE EXTINGUISHERS,

WITH

Bate & Pinkham Attachment.

These Extinguishers are free from every objection, and having the new Bate & Pinkham Attachment, the pressure is not generated until required for use, consequently cannot leak out its power.

They are simple in construction, cannot get out of order, and are easily worked by man, woman or boy.

They have already saved over 500 buildings and property amounting to many millions of dollars.

PRICES:

No. 1, $45. No. 2, $50. No. 3, $55.

☞ Send for a Circular.

AMERICAN CONSOLIDATED

FIRE EXTINGUISHER CO.,

95 Water Street, Boston.

PREMATURE LOSS OF THE HAIR,

Which is so common nowadays, may be entirely prevented by the use of *Burnett's Cocoaine*. It has been used in thousands of cases where the hair was coming out in handsful, and has never failed to arrest its decay, and to promote a healthy and vigorous growth. It is at the same time unrivalled as a dressing for the hair. A single application will render it soft and glossy for several days.

BURNETT'S

FLAVORING EXTRACTS.

The superiority of these extracts consists in their perfect purity and great strength. They are warranted free from the poisonous oils and acids which enter into the composition of many of the factitious fruit flavors now in the market. They are not only true to their names, but are prepared from fruits of the best quality, and are so highly concentrated that a comparatively small quantity only need be used.

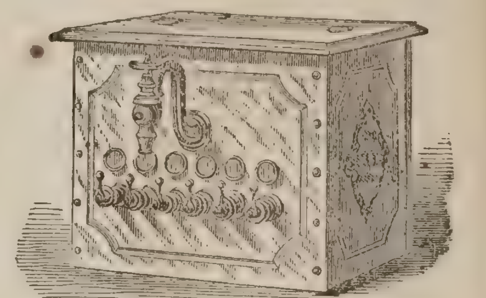
JOSEPH BURNETT & CO.,
BOSTON,

Manufacturers and Proprietors. For sale by all Grocers and Druggists.

The Best Soda Apparatus in the Country.

To increase your sale of Soda Water use

TUFTS' "ARCTIC."



POPULARITY A TEST OF MERIT.

The demand for this Apparatus is still increasing, the sales last season being greater than ever before.
The coming season I shall offer several new and attractive styles, together with an entirely new Counter Soda Apparatus, which I have recently patented, the price of which will meet the requirements of those who wish for a low-priced apparatus.

TUFTS' IMPROVED GENERATOR,

FOR MANUFACTURING SODA WATER.

This Generator combines in its construction the important requisites of

Safety, Simplicity, Economy and Durability,

And is warranted to give complete satisfaction. Descriptive Pamphlets will be mailed Free to any address upon application to the Patentee and Manufacturer.

JAMES W. TUFTS,

No. 33 & 35 Bowker Street, Boston, Mass.

BRANCH OFFICE, 26 MAIDEN LANE, COR. NASSAU ST.,

New York City.

PURE CHLORAL HYDRAT.

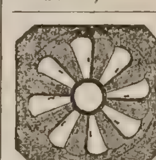
Physicians, in every part of the country, can be supplied with this important agent, from our

LABORATORY,

In its *purest form*. We have it put up in 1 lb., 1 oz. and in ¼ oz. vials, with full directions.

JAS. R. NICHOLS & CO.

FOR SALE. A Homœopathic town and country practice, well-established, and transferable; of from $2,000 to $5,000 a year; 12,000 inhabitants; one hour from New York; house, furniture, horse, &c.
Address, H. F. K., P. O. Box 2750, New York.



GARRAT'S ELECTRIC DISK.

For local rheumatism, weakness, pain or palsy. It is simply to be worn on the body or limb (as if a plaster) for constant localized electricity. While it is active it is easy and perfectly safe in every case. For sale everywhere by first class Druggists.

WE manufacture ENAMELLED EVAPORATING DISHES of different styles, Tinned, Turned and Plain; CORK-SQUEEZERS; ENAMELLED CAULDRONS, 12 to 120 gals.; with a variety of other articles suitable for chemists' use. For sale by

SAVERY & COMPANY,

Corner South Front and Reed Sts., and 614 and 616 Market St., PHILADELPHIA.

PLATINUM Apparatus, Vessels, Sheet, Wire, etc., for all Laboratory and Manufacturing purposes. Platinum Scrap and Ore purchased.
H. M. RAYNOR,
Office, No. 57 Bond Street, New York.

MARK YOUR CLOTHING.—A finely cut Name-Plate, Ink, Brush, and directions for using, sent by mail for *fifty cents*. Fancy styles, *seventy-five* cents. Address,
G. Y. MILLER, LUZERNE, N. Y.

FOR SALE.—A homœopathic town and country practice, worth from $2,000 to $3,000 a year; about thirty miles from Boston. Address,
DR. L. G. LOWE, 136 Washington street, Boston.

BOSTON JOURNAL OF CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. IV.—No. 11. BOSTON, MAY 1, 1870. ONE DOLLAR PER ANNUM, SINGLE NUMBERS TEN CENTS.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston.

TERMS, ONE DOLLAR PER ANNUM, IN ADVANCE.

Contents.

☞ Subscribers will remember that the volumes of the *Journal* commence and end upon the 1st of *July*, not January.

RECEIPTS.—A receipted bill will be sent by return mail to any subscriber who will enclose with his subscription a three-cent postage stamp, for return postage.

A list of premiums is offered to those who obtain subscribers.

☞ Correspondents are particularly requested to give their names in full, with their Town and State; and in case of change of residence, requiring a corresponding change in the mailing of their papers, to give, not only the new address, but the old one also.

☞ We have no complete files of either Vols. 1, 2, or 3; of Vol. I. (originally issued bi-monthly), we have only Nos. 4, 5 and 6 (January, March and May, 1867); of Vol. II. (monthly), we have Nos. 2, 4, 5, 7, 8, 9, 10, 11 (August, October, November, 1867, January, February, March, April, and May, 1868); of Vol. III. we have all the numbers *except* 11 and 12 (May and June, 1869). All the other numbers are out of print, and it is impossible for us to furnish them.

Of the numbers mentioned we have a few copies left, which we will forward to our friends, at the following prices, viz: Vol. I., three numbers, twenty-five cents; Vol. II., eight numbers, fifty cents; Vol. III., ten numbers, fifty cents. Vol. IV. has been stereotyped as issued, and we are able to furnish back numbers since July 1869, to any extent. Price, single copies, six cents; six copies for twenty-five cents.

Familiar Science.

WHERE DO DIAMONDS COME FROM?

UNTIL within a period of one hundred and fifty years, the East Indies furnished all the diamonds found in the markets of the world. In Hindostan and Borneo the precious gems were found in detached crystals, accompanied with grains of gold, amongst metallic sand washed down from the mountains. When the poor miner who wandered into the mountainous districts of Brazil in pursuit of gold accidentally stumbled upon the famous diamond mines of that country, the whole world was filled with excitement, and the number of miners who crowded thither was very great. The quantity of gems of the very first water obtained from these mines was sufficient to keep the gay and luxurious courts of France and Spain in a blaze of light, as the noble ladies of the time adorned their persons with them. The region of country in Brazil in which diamonds are found is extremely limited. The district of Minas Geraes extends only about eighty miles north and south, and eight from east to west. The character of the earth is an agglomerate, formed by the decomposition of granite and mica slate, and is made up of rounded white pebbles and light-colored sand; in this mixture the diamonds are found along with grains of gold, sometimes crystalized. It is curious that the nature of the earth and the deposits corresponds with that of Hindostan and Borneo where diamonds exist. No one knows how a diamond is produced, or where its natural home is. If its original position is a rocky matrix, as is suspected, it is certain no one has ever seen it. The chemist or mineralogist who will furnish a diamond involved in its primitive home, will certainly shed great light upon an interesting scientific problem, and render his name famous. The mountains which supply the *débris* which hold the gems, are composed of schistose rocks, intermixed with quartz, sandstone, brescia, flinty slate, limestone, etc. The limestone brescia is the only rock in which diamonds are found in the mountains, and this comprises all we know regarding their original position. By what subtle chemical processes the brilliants have been formed, at some time, in the course of those stupendous changes to which our planet has been subjected, we have no knowledge. Undoubtedly fire, water, gases, pressure, etc., have all been concerned in the synthetical work. Chemists have not yet been able to manufacture colorless gems, and it is doubtful if the process is ever understood. In an industrial view, the problem has but little practical importance.

It may not be generally known to our readers that new diamond mines have been recently discovered in Australia, and that we are at present receiving from that distant quarter of the world large numbers, and of a brilliancy unsurpassed. In February last the Diamond Mining Co. forwarded to England two hundred and twenty-five diamonds, the produce of four weeks' work with one washing machine. This Company have sent in all, since October, nine hundred and eighty-four stones. Another machine will be at work this summer, which it is expected will more than double the supply. A Mr. Scott, working in the Mudgee district, washed twelve loads of earth and obtained one hundred and ten gems, weighing three and one half dwt., equal to 26 carats; nine of them weighed one carat each. The miners earn about £12 a week, or $60 our currency. A party of miners owning about eight acres of territory have refused $20,000 for one half interest in the "diggings." It is evident that the world is about to receive from Australia a large accession to its diamond treasures, and it is possible that the quantity will be so large as greatly to unsettle prices. The value of diamonds is based upon an arbitrary standard, and a considerable increase in the supply will have the effect to create a panic among holders, and values will fall to a much lower point. Our wealthy and fashionable ladies may yet live to see the brilliants flashing upon the bosoms of their servants in the kitchen, and from the cravats of the Johns and the Patricks in the stables. No very serious disturbance to the world's well-being will result, if this revolution in the value of diamonds should occur.

DUST AND DISEASE.

PROF. TYNDALL's lecture on this subject, before the Royal Institution, has made a great sensation on both sides of the Atlantic. Singularly enough, both the lecturer and the majority of those who heard or who have read his lecture, appear to consider that the *organic* character of "the gay motes that people the sunbeam" is a new discovery. The Professor himself, after telling how he burned up this floating dust, says: "I was by no means prepared for this result; for I had thought, with the rest of the world, that the dust of our air was, in great part, inorganic and non-combustible."

But, as Dr. R. Angus Smith has stated in a paper published since Prof. Tyndall's lecture, "the knowledge of organic matter in the air has never been absent entirely from men's minds in historic times"; and the truth has never been more completely expressed than by Bishop Berkeley, in *Siris*:—

"Nothing ferments, vegetates, or putrefies, without air, which operates with all the virtues of the bodies included in it,—that is, of all nature. . . . The air, therefore, is an active mass of numberless different principles,—the general sources of corruption and generation; on the one hand, dividing, abrading, and carrying off the particles of bodies, that is, corrupting or dissolving them; on the other, producing new ones into being, destroying and bestowing forms without intermission. . . . The seeds of things seem to be latent in the air, ready to pair, and produce their kind whenever they light on a proper matrix. The extremely small seeds of ferns, mosses, mushrooms, and some other plants, are concealed and wafted about in the air, every part whereof seems replete with seeds of one kind or other. The whole atmosphere seems alive. There is everywhere acid to corrode and seed to engender. Iron will rust, and mould will grow in all places."

As long ago as 1846, Dr. Smith described, before the Chemical Society, a simple method of obtaining organic

matter from the condensed breath on windows. This attracted sufficient attention at the time to lead the British Association to request him to examine the subject further, and report upon it. He did so, and his report was published in 1848. The following are extracts therefrom:—

"That animals constantly give out a quantity of solid organic matter from the lungs, may readily be proved by breathing through a tube into a bottle, when the liquid or condensed breath will be collected at the bottom of the bottle; or by breathing through a tube into water, when a solution of the same substance will be found in the water. This would scarcely require proof if we consider that breath so frequently has an organic smell.

"If this condensed breath be put on a piece of platinum, or on a piece of white porcelain, and burnt, the charcoal which remains and the smell of organic matter will be conclusive. If it be allowed to stand for a few days (about a week is enough), it will then show itself more decidedly *by becoming the abode of small animals.* These are rather to be styled animalculæ, and very small ones certainly, unless a considerable quantity of liquid be obtained; they may be seen with a good microscope. Animalculæ are now generally believed to come from the atmosphere and to deposit themselves on convenient feeding places; that is, they only appear where there is food or materials for their growth, and they prove, of course, the existence of that continuation of elements necessary for organic life. At the same time, their presence is a proof of decomposing matter, as their production is one of the various ways in which organized structure may be broken up."

In 1866 again, in a Report to the Cattle Plague Commission, Dr. Smith refers to Pasteur's investigations in the same field, in the following terms:—

"It would appear as if oxygen were not the only agent in the atmosphere causing decomposition. The investigations of M. Pasteur, who found the subject in this uncertain condition, have advanced it so far that we may now with certainty reason in the belief that organized substances are really found in great abundance in the atmosphere (in all places), and that they are the cause of some hitherto entirely mysterious phenomena, putrefaction included. His object was first to inquire into the possibility of spontaneous generation, and he found that carefully filtered air allowed no organisms to appear in vegetable solutions. He found that near the usual surface of the ground these organisms were so numerous that whenever a vessel containing vegetable matter fit for their growth was opened for a very short time they were found to enter; that in cellars and damp and quiet places, where there was no air or dust floating about, these organisms were fewer; and that, as he ascended the sides of the Alps and the Jura, they diminished in number. A commission of the French Academy confirmed his results."

For some years past, Dr. Smith has been attempting to *measure* the amount of this putrescible matter in the air of different places, and also the amount that has undergone putrefaction and left its remains in the air,—"the sewage of the atmosphere," as he forcibly expresses it. In this attempt he has succeeded to a considerable extent, and the results are to be published in a work on "Chemical Climatology."

Prof. Tyndall cannot claim, therefore, to be the discoverer of the organic character of the dust in the air. Nor has he advanced our knowledge with regard to the "germ theory of disease," which, as "*Nature*" reminds him, is neither confirmed nor refuted by his investigations. What he *has* discovered is an easy, and, at the same time, a very clear and striking method of *showing to the eye* that the dust in the air is largely organic. The practical results of his experiments, so far as health is concerned, are summed up by "*Nature*" thus:—

"Prof. Tyndall has given us a scientific account not only of certain optical properties of impure air, but likewise of the benefit of several popular practices; such, for example, as lighting fires during epidemics, to purify the air; the use of gauze curtains in malarious districts, as a protection against fever; covering the mouth with cloth during sleep in fever countries, and the like. He has shown that heat purifies, more or less, impure air; and that impure air can be deprived of its suspended impurity by filtering it, as is the case with water. On the real proximate aërial cause of disease, if such there be, no new light has been yet thrown by the optician, the microscopist, or the chemist."

Scienti[illegible] men are fast coming to the conclusion that *carbonic acid*, which has so long been held responsible for most of the mischief done by bad air, is by no means so pernicious as has been supposed, and that a large part of the mischief ascribed to it should really be charged to these *organic* impurities in the atmosphere. On the other hand, as Doctor Smith suggests, it is not to be taken for granted that *all* the organic matter in the atmosphere is necessarily injurious to health. Of these organized germs some are unquestionably hurtful, but "it may be that others are required for the maintenance of healthy animal life, exactly as in vegetable fermentation." Many workers are already busy in this field of research, and Prof. Tyndall's experiments will attract increased attention to it, while they suggest a new method of conducting the investigation, and one that will doubtless lead to fresh discoveries of the greatest interest and importance, both theoretically and practically.

GASES AND LIQUIDS.

One of the most interesting and most important of recent discoveries is that of "the continuity of the gaseous and liquid states of matter," by Dr. Thos. Andrews, Vice-President of Queen's College, Belfast. He has proved experimentally that these two states are nothing more than widely separated forms of the same condition of matter, and that they may be made to pass into one another by gradations so gentle that there shall nowhere be a perceptible breach of continuity. Carbonic acid has thus been carried from the gaseous to the liquid state, without break or interruption. Dr. Andrews has lately illustrated this in a lecture before the Royal Society, from the concluding paragraphs of which we give the following extracts:—

"Take, for example, a given volume of carbonic acid gas at 50° C., or at a higher temperature, and expose it to increasing pressure till 150 atmospheres have been reached. In this process its volume will steadily diminish as the pressure augments, and no sudden diminution of volume, without the application of external pressure, will occur at any stage of it. When the full pressure has been applied, let the temperature be allowed to fall till the carbonic acid has reached the ordinary temperature of the atmosphere. During the whole of this operation no breach of continuity has occurred. It begins with a gas, and by a series of gradual changes, presenting nowhere any abrupt alteration of volume or sudden evolution of heat, it ends with a liquid. The closest observation fails to discover anywhere indications of a change of condition in the carbonic acid, or evidence, at any period of the process, of part of it being in one physical state and part in another. That the gas has actually changed into a liquid would, indeed, never have been suspected, had it not shown itself to be so changed by entering into ebullition on the removal of the pressure. . . . From carbonic acid as a perfect gas to carbonic acid as a perfect liquid, the transition we have seen may be accomplished by a continuous process, and the gas and liquid are only distant stages of a long series of continuous physical changes. Under certain conditions of temperature and pressure, carbonic acid finds itself, it is true, in what may be described as a state of instability, and suddenly passes, with the evolution of heat, and without the application of additional pressure or change of temperature, to the volume which, by the continuous process, can only be reached through a long and circuitous route. In the abrupt change which here occurs, a marked difference is exhibited, while the process is going on, in the optical and other physical properties of the carbonic acid which has collapsed into the smaller volume, and of the carbonic acid not yet altered. There is no difficulty here, therefore, in distinguishing between the liquid and the gas. But in other cases the distinction cannot be made; and under many of the conditions I have described it would be vain to attempt to assign carbonic acid to the liquid rather than the gaseous state. Carbonic acid, at the temperature of 35·5°, and under a pressure of 108 atmospheres, is reduced to 1-430th of the volume it occupied under a pressure of one atmosphere; but if any one ask whether it is now in the gaseous or liquid state, the question does not, I believe, admit of a positive reply. Carbonic acid at 35·5°, and under 108 atmospheres of pressure, stands nearly midway between the gas and the liquid; and we have no valid grounds for assigning it to the one form of matter any more than to the other. The same observation would apply with even greater force to the state in which carbonic acid exists at higher temperatures and under greater pressures than those just mentioned. . . . The properties thus exhibited by carbonic acid are not peculiar to it, but are generally true of all bodies which can be obtained as gases and liquids. Nitrous oxide, hydrochloric acid, ammonia, sulphuric ether, and sulphuret of carbon, all exhibited, at fixed pressures and temperatures, critical points, and rapid changes of volume with flickering movements, when the temperature or pressure was changed in the neighborhood of those points."

Dr. Andrews closes his lecture thus:—

"A problem of far greater difficulty yet remains to be solved, the possible continuity of the liquid and solid states of matter. The fine discovery made some years ago by James Thomson, of the influence of pressure on the temperature at which liquefaction occurs, and verified experimentally by Sir W. Thomson, points, as it appears to me, to the direction this inquiry must take; and in the case at least of those bodies which expand in liquefying, and whose melting points are raised by pressure, the transition may possibly be effected. But this must be a subject for future investigation; and for the present I will not venture to go beyond the conclusion I have already drawn from direct experiment, that the gaseous and liquid forms of matter may be transformed into one another by a series of continuous and unbroken changes."

The Physiological Effect of the Ruhmkorff Spark.—It has been taken for granted that to allow the spark of a large Ruhmkorff coil to pass through the body would be dangerous, if not fatal; but recent experiments by Dr. Richardson, in England, have proved that this is an error. Our readers have heard of the immense Ruhmkorff coil at the "Royal Polytechnic," in London, which gives a spark of 25 or 28 inches. Dr. R. sent the charge of this powerful machine through a pigeon, which had previously been put under the influence of anæsthetics. Each spark caused a general muscular contraction, but the action of the heart and of the respiratory organs was not affected, and the bird came out of the experiment unharmed, except for the ruffling of its feathers. A frog was then subjected to a similar trial, with a like result. To one who has witnessed the action of this monster coil, which in its luminous and calorific effects as far exceeds an ordinary induction coil as the latter surpasses a common Leyden jar, this seems scarcely credible. Whether the experimenter allowed the spark to pass through any part of his own person, after trying it on the pigeon and the frog, is not stated in the only account of the investigation that we have seen; but if *they* could stand it, there could be no serious risk in a man's taking a similar dose of artificial lightning.

Vine Culture in France.—According to the Bulletin of the Scientific Association of France, the vine occupies in that country 2,500,000 hectares, or 6,175,000 acres,—the sixteenth part of all the land capable of cultivation. The gross produce amounts to 1,500,000,000 francs, or about $300,000,000 in gold. This industry gives employment to six million men, women, and children, and nearly two million merchants, agents, etc.

Cologne Vinegar.—To one pint of good *eau de cologne*, add half an ounce of strong acetic acid. This mixture is much used in France as an application in nervous headaches, etc.

VICTORIA AND ITS GOLD.

THE population of the Australian colony of Victoria has risen from 77,000, in 1851, to 660,000, in 1867, and its acres under cultivation from 57,000 to 631,000. Its imports and exports are tenfold what they were in 1851, and the valuation of taxable property in town and country is estimated at £42,000,000.

This marvellous growth is mainly due to the discovery of gold in 1851. The richness of the gold-fields is shown by the fact that, from 1851 to the end of 1868, the yield had been 36,835,691¾ ounces, worth £147,342,767. The annual product is, however, steadily diminishing. In 1856, the quantity exported was 2,985,991 ounces, while in 1868 it was only 1,657,498 ounces. In 1854, when the gold fever was at its height, the number of miners was 65,763; but it has slowly fallen off, and in Sept., 1868, was 63,482.

Silver, tin, copper, antimony, zinc, lead, cobalt, bismuth, manganese, and iron are found in Victoria, some of them abundantly. Coal, lignite, and bituminous shales are also met with; and the sapphire and the diamond are to be added to the list.

HOUSEHOLD RECIPES.

TO IMPROVE STARCH.—To each bowl of starch, add one teaspoonful of Epsom salts, and dissolve in the usual way by boiling. Articles starched with this will be stiffer, and will be rendered to a certain degree fireproof.

TO REMOVE STAINS FROM LINEN.—To remove wine, fruit, or iron stains, wet the spot with a solution of hyposulphite of soda, and sprinkle some pulverized tartaric acid upon it; then wash out as usual. Strong vinegar can be used instead of the tartaric acid.

MOTH POWDER.—Lupulin (flour of hops), 1 dram; Scotch snuff, 2 oz.; gum camphor, 1 oz.; black pepper, 1 oz.; cedar sawdust, 4 oz. Mix thoroughly, and strew (or put in papers) among the furs or woollens to be protected.

LIQUID FOR CLEANING SILVER.—Add gradually 8 oz. of prepared chalk to a mixture of 2 oz. of spirits of turpentine, 1 oz. of alcohol, ½ oz. of spirits of camphor, and 2 drams of aqua ammonia. Apply with a soft sponge, and allow it to dry before polishing.

Arts.

NEW THINGS IN THE ARTS.

TUNGSTEN BLUE.—M. Tessié du Motay, whose name is already familiar to our readers in connection with the new method of obtaining oxygen gas cheaply on a large scale, has announced the discovery of a new coloring substance. It has a striking resemblance to Prussian blue, but differs from it in not being bleached by sunlight. Like that substance, it resists the action of acids, but not of alkalies. The directions for preparing it are as follows: Dissolve, in a sufficient quantity of water, and successively, 10 parts of tungstate of soda, 8 of tin-salt (protochloride of tin), 5 of ferrocyanide of potassium, and 1 of perchloride of iron. When all these substances are dissolved, the mixture is thoroughly stirred up, and the sediment which is formed is separated by filtration. As soon as the liquid has run off, the moist pasty matter is spread out in thin layers upon suitable glass plates, or shallow dishes, and for several days exposed to the action of strong daylight and sunshine. This slowly causes the formation of a beautifully-blue pigment; and this action may be accelerated by washing the material, so as to remove the matters soluble in water which it yet contains. The tungsten blue can be heated to about 180° C. without decomposition. Its percentage composition in 100 parts, is—water, 7·85; tin, 31·69; iron, 5·13; cyanogen, 19·41; blue oxide of tungsten, 35·60; total, 99·68. It costs no more than the finest quality of Prussian blue.

WATERPROOFING PAPER.—The solution of oxide of copper in ammonia acts, as is well known, as an energetic solvent of cellulose, or woody fibre. Advantage is taken of this fact in waterproofing paper by the following process:—

A tank is made to contain the solution just alluded to, and the paper is rapidly passed just over and in contact with the surface of the liquid, by means of properly placed rollers moving with speed. The paper, on leaving, is pressed between two cylinders, and next dried by means of so-called drying cylinders, similar to those in use in paper mills. The short contact of the felty paper tissue with the liquid gives rise to just sufficient solution of cellulose to form an impermeable varnish.

WATERPROOFING WOVEN FABRICS.—A late number of *Cosmos* gives the following method:—

1 kilo. of alum is dissolved in 32 kilos. of water, and 1 kilo. of acetate of lead is dissolved in the same quantity (separately) of water. The two liquids having been mixed, there is, of course, precipitated sulphate of lead; as soon as this is deposited, the clear liquid is decanted, and the fabric which it is desired to render waterproof is thoroughly steeped in this fluid, and next dried by being hung up in open air.

COPPER WINDOW SASHES.—These sashes are now manufactured in England under patent. The metal used is drawn copper, and is hard and tough. The sashes, when completed, are submitted to a bronzing process and are not affected by atmospheric influences. They have been experimentally proved to be weather tight, and are thus peculiarly adapted for resisting the attacks of heavy rain in exposed situations. The manner in which the parts are put together precludes the possibility of rattling in high winds. Once fixed, these sashes require no painting or other attention. The glass is embedded in an impermeable putty, and fixed in its place by strips of copper attached with screws of the same metal. The first cost is slightly beyond that of the ordinary sashes, but their unquestionable durability more than compensates for the extra outlay.

LACQUERS.

1. *Deep Golden Lacquer.*—Seed lac, 3 oz.; turmeric, 1 oz.; dragon's-blood, ¼ oz.; alcohol, 1 pint. Digest for a week, shaking frequently; then decant and filter.

2. *Golden Lacquer.*—Turmeric, 1 lb.; gamboge, 1½ oz.; gum sandarach, 3½ lbs.; shellac, ¾ lb. (all in powder); rectified alcohol, 2 gallons. Dissolve, strain, and add 1 pint of turpentine varnish.

3. *Red Lacquer.*—Spanish annatto, 3 lbs.; dragon's-blood, 1 lb.; gum sandarach, 3¼ lbs.; rectified alcohol, 2 gallons; turpentine varnish, 1 quart. Dissolve and mix, as in No. 2.

4. *Pale Brazen Lacquer.*—Gamboge (cut small), 1 oz.; Cape aloes (do.), 3 oz.; pale shellac, 1 lb.; rectified alcohol, 2 gallons. Dissolve and mix, as in No. 2.

5. *Another Brazen Lacquer.*—Seed lac, dragon's-blood, annatto, and gamboge, each, 4 oz.; saffron, 1 oz.; rectified alcohol, 10 pints. Dissolve, etc., as in No. 2.

As these lacquers are often wanted of different shades of color, it is well to keep on hand a concentrated solution of each coloring ingredient, so that it may be added at any time to produce the desired tint.

USEFUL RECIPES.

MUCILAGE FOR LABELS.—Macerate five parts of good glue in eighteen or twenty parts of water, for a day, and to the liquid add nine parts of rock candy and three of gum arabic. The mixture can be brushed upon paper while lukewarm. It keeps well, does not stick together when dry, and adheres firmly to bottles when moistened.

For the labels of soda and seltzer water bottles (or for any bottles kept in damp cellars), make a paste of good rye flour and glue, and to each pound of it add half an ounce of linseed oil varnish and half an ounce of turpentine.

An excellent paste for the manufacture of portfolios is made by preparing a saturated solution of borax in hot water and filtering it when cold. It is then to be heated and as much well washed and dried caseine dissolved in it as it will take up. This is to be used when cold, and is said to be much superior to glue.

ZINC WHITEWASH.—Mix oxide of zinc with common size, and apply it with a whitewash brush to the ceiling. After this, apply in the same manner a wash of the chloride of zinc, which will combine with the oxide to form a smooth cement with a shining surface.

TO TIN IRON COLD.—Take equal parts of quicksilver and block tin, and melt them together. Mix also equal parts of muriatic acid and water. Apply the amalgam with a clean rag steeped in the acid mixture.

AN AMALGAM FOR ELECTRICAL PURPOSES.—Those who have occasion to experiment with frictional electricity will be glad to know of a new amalgam, which is much better than the one in common use (two parts quicksilver, one of tin and one of zinc). It is made by melting two parts of chemically pure zinc in an iron ladle, and then carefully adding, while gently stirring it with an earthen pipe-stem, one part of quicksilver. After cooling, an extremely tough, but easily pulverized amalgam, of a silver white color, is obtained, which may be kept in closed vials for any length of time; and when needed, the necessary quantity is to be ground up in a porcelain mortar, with a little tallow.

In the construction of electroscopes, aluminium foil is much superior to gold foil, being equally sensitive, while it is much stronger and less liable to be torn.

TO PASTE PARCHMENT PAPER.—It is well known that it is not easy to make surfaces of parchment paper adhere by means of common paste. If, however, the surfaces are moistened with dilute alcohol or other spirits before applying the paste, they will adhere with the greatest tenacity.

COMPOSITION FOR WALKS.—The following is highly commended, and is not patented:—

Sand, 5 parts; coal ashes, 2 parts; slaked lime, 1 part; fine gravel, 2 parts. Mix cold, and add coal tar, hot or cold, until the mass becomes just sticky with it. Make the foundation of the walk by ramming down or rolling hard 6 inches of gravel; then put on a three-inch layer of the mixture, and roll or pound very hard.

PRESERVATION OF MILK. *Cosmos* gives the following recipe:—

Add to every litre (about 29 ounces) of unskimmed milk, previously poured in a well-annealed glass bottle, 40 centigrms. (about 6 grs.) of bicarbonate of soda. Place the bottle containing the milk, well corked, for about four hours in a water-bath heated up to 90° (194° F.). On being taken out, the bottle is varnished over with tar; and in that state the milk it contains will keep sound and sweet for several weeks.

To Preserve Steel Goods from Rusting.—The simplest way of preventing the oxidation of polished iron and steel goods is to dust them over with quick lime. When articles are required to be preserved for many months (such as polished steel grates), strips of paper freely covered with powdered lime are to be wrapped around the bars; or they may be placed in cases, and interstices filled up with quick lime. Pianoforte wires and small goods are preserved in the same way. The *rationale* of the method is this—steel will not oxidize in dry air, and thus indirectly the lime preserves steel from rust. This is not a new plan, but it is the method adopted by the majority of the Birmingham houses.

Purification of Water.—Dr. Dunning, of Amsterdam, recommends for the purification of dirty water, for household and manufacturing purposes, the addition of half a grain of chloride of iron to each quart of the water. By this means the foreign constituents are deposited, and by a further addition of about one and a third grains of soda to a quart of the water, the iron is precipitated. Experiments made on a large scale, in Holland, upon impure river water, gave the most satisfactory results.

Cement for Aquaria.—A correspondent, who has made hundreds of aquaria, and who has experimented with numerous cements for the purpose, writes us that the following is much better than the one for which we gave a recipe in our last number:—

Take 10 parts by measure of litharge,
10 " " " " plaster of Paris,
10 " " " " dry white sand,
1 " " " " finely powdered rosin,

and mix them, *when wanted for use*, into a pretty stiff putty with boiled linseed oil. This will stick to wood, stone, metal, or glass, and hardens under water. It is also good for marine aquaria, as it resists the action of salt water. It is better not to use the tank until three days after it has been made.

Waterproof Varnish.—Take 2 parts of rectified petroleum spirit, in which dissolve 2 parts of prepared gum dammar, and filter or strain the whole. In making paints, take stearic acid or paraffine, alone or in combination, and reduce them by means of heat to a liquid state. To every 8 lbs. of paraffine or stearic acid, alone or in combination, add 2 lbs. gum dammar. The paints may be colored by any suitable coloring matter, and may be applied in a heated state; or when used cold, may be diluted to a suitable consistency by means of rectified petroleum spirit.

Stucco.—This substance, now much in use for walls, pillars, etc., is at present prepared by mixing plaster of Paris with a solution of gelatine or glue, instead of with water. This, while stiffening more slowly, becomes much harder than with water alone. For white stucco, the proper quality of gelatine must be employed; for colored, less care need be exercised. When the mass has been suitably applied, and sufficiently hardened, the surface is to be moistened and rubbed down with pumice stone until smooth. It is finally to be coated by means of a brush with a concentrated solution of gelatin, and, when perfectly dried, it may be polished with tripoli on a buffer, with the addition of a little olive oil. It is often desirable, in using plaster of Paris in the ordinary way, to prevent its hardening too rapidly. This may be easily done by adding a saturated solution of borax to the water in suitable proportion. One volume of the solution to twelve of water will prevent hardening for fifteen minutes; while with equal parts this will not take place for ten or twelve hours.

Genuine Port Wine.—Cider, 14 oz. Alcohol, 3 oz. Strong decoction of logwood, 4 oz. Alum, 40 grains. Cream of tartar, 20 grains. White sugar, 1¼ oz. This, being a *native* wine, is largely patronized in America. By all means, make it for yourself. It will be much cheaper than to buy it, and you will have the satisfaction of knowing that it is unadulterated.

THE TESTING OF KEROSENE.

There has been a good deal of dispute and some litigation, in England, in regard to the method of testing petroleum and similar oils which is prescribed by law. The discordant results obtained by different chemists in testing samples of the very same oil have led scientific men to investigate the subject very carefully, and the conclusions to which they have come are of great practical importance.

In the first place, it is found that the *time* taken to heat the oil up to the "flashing point" has a marked influence upon the result. In experiments made by Mr. Calvert upon six different samples of oil, it was found that when they were heated from 52° F. up to the flashing point in fifteen minutes, they "flashed" at temperatures *from 2° to 8° lower* than when twenty minutes were taken to heat them to the same extent; and in the latter case they flashed at temperatures from 2° to 9° lower than when thirty minutes were spent in the process. Thus the very same oil, heated for fifteen minutes, flashed at 95°; heated for twenty minutes, flashed at 99°; for thirty minutes, flashed at 108°. All three tests would be consistent with the wording of the law (which merely directs the use of "a small flame" in heating the oil); but while two of them would condemn the oil and subject the seller to a penalty, the third would prove it safe for sale or use.

This difference is probably due to the fact that when the oil is heated slowly, the more volatile products escape gradually into the air, and are never present in sufficient quantity to produce a flash when a taper, as directed by the act, is passed within a quarter of an inch of the surface of the oil.

Again, it is found that, if two thermometers are placed in the oil, one (as the act prescribes) one and one-half inches below the surface, and the other only one-half inch, there will be a difference of several degrees between the two at the time of the flash. In three experiments, the difference was 5°, 4°, and 4°, respectively.

This very curious and unusual difference in the temperature of a fluid near the surface, and at a point an inch lower, is probably to be ascribed to the fact that the oil is not a homogeneous liquid, but a mixture of several hydrocarbons; the lightest of which rise first to the surface, carrying the heat with them.

Mr. Calvert recommends that the vessel containing the oil should be heated by setting it into a vessel of water, previously heated to some 10° above the probable flashing point—or to about 110°—and that the bulb of the thermometer be placed half an inch below the surface of the oil. The flashing point is then to be tested in the usual way. A variety of experiments with this method gave uniform and consistent results.

JOTTINGS.

A Soda Mine.—The *Gold Hill News* gives an account of a soda mine in Nevada, which is as singular as it is valuable. It is an immense and apparently inexhaustible deposit of almost pure soda. It is free from all earthy matter, and yields 80 per cent of soda, the balance being mainly salt. A shaft has been sunk beside it to the depth of fifty feet, from the bottom of which a drift has been made for 25 feet into the vein of soda, without getting through it. The owners sell the soda to soap manufacturers in the State, and also as a chemical agent in the reduction of ores. It is also used for washing and other purposes for which ordinary soda is employed.

Oxygen Peddled in the Streets of Paris.—Oxygen is now made on a large scale in Paris. Carts, with metal reservoirs containing the compressed gas, deliver it to customers in all parts of the city. Some of the theatres are large consumers, using it for illumination both outside and inside. The oxyhydrogen light is also much used for the illuminated advertisements that are now so common on the Boulevards and elsewhere. These are produced by a magic lantern and screen in the second stories of buildings, and the furnishing of them has become quite a business.

Good News, if True.—It is stated that M. Tessié du Motay (may his shadow never be less!) has devised an oxyhydrogen light, in which no pencil of lime, magnesia, or zircon is required. Supercarburetted hydrogen is used instead of ordinary hydrogen. The new light is wonderfully cheap, as well as brilliant, costing only two centimes (*less than half a cent*) for five hours. If there is no mistake about this (and it comes on good authority), the old-fashioned mode of gas-lighting may be considered as "played out."

The Newall Telescope.—This new instrument, made by Cooke & Sons, of York, Eng., for R. S. Newall, of Gateshead, is now completed. A full description of it, with illustrations, is given in No. 16 of *Nature*. The object-glass has a clear aperture of twenty-five inches. The great refractor at Cambridge, Mass., has but fifteen and one-half inches aperture, and the one made by Alvan Clark, for the Chicago Observatory, eighteen and one-half inches. This last was the largest refracting telescope in the world, but is thrown quite into the shade by this new English instrument. The light-collecting capacity of the latter is nearly *double* that of the former, or as 625 (the *square* of 25) is to 342.25 (the square of 18.5). After being thoroughly tested, the telescope is to be removed to some climate more favorable for astronomical observations than that of England.

Last Words over two Great Works.—"*Gesta dei per Francos*, le Canal de Suez est l'œuvre de Dieu et de la France," says M. Lesseps, at the conclusion of his labors. "We've got through praying and are going to strike," was the message which sped from Promontory Point to all the cities of the Union, after the thanksgiving had been uttered, and the hammer was about to descend on the last spike which completed the Pacific Railway. As *Engineering* remarks, these utterances are characteristic of the two great nations that had achieved two great national undertakings.

Alcohol and Soda.—It has long been known that soda is not only unable to dry alcohol, but that it actually moistens it; but the fact has only recently been explained. It appears that the sodium replaces the hydrogen of the alcohol, while the displaced hydrogen combines with the oxygen of the decomposed soda, and thus forms water.

Southern Ice for Northern Cities.—One of the curiosities of this singular season is the sending to the South for ice to eke out the deficient supply from the native "crop." The *Picayune* says, that New Orleans now manufactures its own ice by steam, and that the Louisiana Ice Company recently received an order from Philadelphia for fifty tons of the product. The editor adds, "We shall be supplying Boston next, though that would indeed seem like sending coals to Newcastle."

Agriculture.

ABOUT MANURES.

At this season of the year, when farmers are employed in preparing their fields for the growth of crops, the question of manures becomes one of the first importance. We have repeatedly pointed out to farmers the great difference existing in manures which are alike in physical appearances, and also we have shown to be erroneous the notion that bulk in manurial substance affords evidence of value. A cord of barnyard manure taken from the premises of one farmer may be worth ten dollars, while the same quantity from another may not have half that value. Animal excrement as a marketable commodity has a fixed price in our towns and cities, and no variations are made, based upon assumed differences in fertilizing value. And yet, if exact justice were done to seller and purchaser, and the price based upon actual value, it would present as wide a range as is found in different qualities of cloths or groceries. The excrement sold by one stable keeper or farmer, who feeds his horses and cows upon rich upland grasses, with an abundance of grain, would hold more than double the amount of soluble plant nutriment contained in that of another, who supplied to his animals only meadow hay and small quantities of the cereals. The vender of excrement who carefully houses it, and retains in association much of the liquid portion, supplies an article of *twice* the value of that produced from the same rich foods, but left out of doors in yards, exposed to the winds and drenching rains. This matter of exposure of manures is so important, the injury from exposure being really so great, we cannot speak of it too earnestly. The fertilizing elements in excrement are mostly soluble in water, and when the barnyards are drenched with it, they usually overflow, and the valuable portions are carried away. The farmer who hauls out his manure in the autumn, and leaves it in a heap upon his field, cannot fail to notice the extreme fertility of the spot where it was deposited. For several consecutive years vegetation grows upon it in rank luxuriance, and it is a marked feature in the cultivated field. By the leaching influence of rain-water, the salts are removed from the dung and carried into the soil, and if that be porous or silicious, a considerable portion is carried down so far as to be beyond the reach of plant roots. The loss from this treatment of manure is very great, and it cannot be shown in a more striking or conclusive way, than by presenting an analysis of a specimen of manure taken from a water-soaked heap, and another from a parcel preserved in a barn cellar. The exposed manure furnished,

Nitrogen	1.35 per cent
Soluble organic matters,	1.78 " "
Soluble inorganic matters	2.67 " "
Phosphoric acid	0.20 " "
Potash and soda	0.79 " "

The cellar manure furnished,

Nitrogen	1.88 per cent
Soluble organic matters	6.22 " "
Soluble inorganic matters	3.98 " "
Phosphoric acid	0.29 " "
Potash and soda	2.00 " "

It will be noticed that in the nitrogen (ammonia-forming constituent), the soluble organic and inorganic bodies, and potash and soda salts, there is a loss in the exposed manure, which renders it of less than half the money value of the other. The quality and the preservation of manures supply topics which should be presented to farmers very often, that they may be led clearly to understand the whole subject, and provide against losses, which are of a most serious nature. We shall refer to this important matter again.

A FALSE THEORY FROM A TRUE PRINCIPLE.

Editor Boston Journal of Chemistry: —

In the case of the fruit trees, mentioned in the Journal for February, there is no doubt that the girdling was the cause of the abundant fruitage; but it by no means follows from this fact that a general principle can be deduced, that trees would be improved, or the crop increased for a series of years, by such treatment. It is well known that gardeners frequently girdle a branch, by removing a narrow ring of bark around it, when they wish to increase the size and beauty of the fruit; but it is done at the expense of its vitality, and, unless the operation is skilfully performed, will invariably destroy it before the season of bearing the next year.

The crude sap, taken up from the soil by the roots of the tree, ascends principally through the vascular tissue of the alburnum, or sap-wood, to the leaves of the branches, and there both this and the carbon of the carbonic acid, absorbed from the air by the leaves, are organized into the proper substance for the growth of the wood and fruit. It then descends on the outside, principally through the sieve tissue of the cambium layer, forming a new layer of wood and bark; while a part also goes to the nourishment of the fruit. If there is no obstruction of the elaborated sap in its downward course, it is equally distributed to the branches, fruit, stem, and roots; but, if the bark and cambium layer are removed by girdling, it is stopped in its descent, and consequently received into the branches and fruit in excess, and they are thus increased at the expense of the part below. In this way we account for the increase of the fruit by girdling.

Professor John Lindley, when speaking of this subject in his late treatise on horticulture, quotes Mr. T. A. Knight approvingly, as follows: "When the course of the descending current is intercepted, that naturally stagnates, and accumulates above the decorticated space, whence it is repulsed and carried upward, to be expended in an increased production of blossoms and fruit." This theory is adopted by the best physiologists of the present time, and can be demonstrated with almost mathematical certainty. Therefore, this unnatural development of fruit, instead of indicating an improvement of the trees, must be looked upon as a premonitory symptom of disordered physical action, and of premature death.

If the bark and the cambium layer have been removed by girdling, as seems to be the case with the trees, the downward circulatory connection on the outside between the upper and the lower part is destroyed, and the upper part at least must die. If, however, the cambium layer has not been destroyed, and has been so covered by wax and bandages as to prevent evaporation and drying of the surface of the decorticated part, there is a chance for some of them to live. It is true that some few cases are recorded of trees which have lived several years after the bark and cambium layer have been removed, but they are of very doubtful authority.

M. Ernest Faivre, a French physiologist, gives a statement of his recent investigations on this subject, published in the *Gardener's Chronicle*, about two months ago, in which he says: "In mulberry trees, as in all trees deprived of latex, annular incisions generally produce the following manifestations: 1. Formation of a swelling, or tissue restorer, at the upper lip of the wound. 2. Diametrical growth of the parts above the zone of bark taken off. 3. Hardening of the wood in that region. 4. Stationary condition of the parts below, if they are deprived of leaves and buds; or, if not, vigorous shoots from below the lower lip of the wound. 5. More easy, more early, and more abundant flowering and fructification. 6. Destruction, after a variable time, of all the parts above the annulation."

From the foregoing observations it appears that girdling trees in any form is ruinous, and almost always fatal; therefore I heartily concur in the advice given in the Journal that orchardists should not experiment on their trees too freely before they see what the final result will be with those already girdled. P.

Germination of Seeds.—The sprouting of seeds can be facilitated by chemical agencies, especially by the action of ammonia and oxalic acid. A solution of the latter will often cause them to germinate within a day or two, even after having been kept for forty years. Coffee seeds, which are proverbially hard to start, are best forwarded by placing them in a covered vessel containing equal parts of water and spirits of sal ammoniac, at the ordinary temperature. At the end of twelve hours the roots will be found to have started. Most of the stories of the germination of wheat found in mummy cases are of very dubious character. Travellers and others have often been "sold" by the Egyptian rascals who have furnished them with these seeds of two thousand or more years ago. It is stated, however, on pretty good authority, that in 1834, at a meeting of a German Scientific Association, grain was exhibited which had been raised from seed found in an Egyptian tomb, where it must have lain for twenty or twenty-five centuries. This seed had been soaked for a considerable time in fatty oil before planting.

HOW MEADOW HAY MAY BE DISPOSED OF.

Those who are obliged to feed meadow hay to their cattle wholly or in part, at this season, know full well that their animals have but little relish for it, and that it lacks the necessary nourishment to keep them in condition. We recently tried a little experiment that proved to our mind that there is a way in which such kind of hay may be prepared so that it will be eaten readily; and though it lacks the nourishment of better feed, we think cattle could be made to thrive upon it.

Looking through the barn, and meditating upon the possibility of being short of the better kinds of hay, especially if the spring should be late, and having more meadow hay than will be needed for bedding — a kind of hay, by the way, that the cattle will eat but little of at this season — we run a forkful through the hay-cutter, turned hot water upon it, and to what would fill a half bushel, two quarts of meal were added. After a thorough mixing it was covered up, and left to steam and soak for an hour, when it was placed before a cow that is kept upon as good fodder as the barn affords, with a little something else besides. The mixture was as greedily devoured as if it had been the sweetest rowen. Not a particle was left. Another lot was prepared and given to another cow with the same result. We did not lose any sleep that night on account of the possibility of being short of hay, for we feel confident that at least one foddering per day of cut meadow hay, prepared as above, may be fed to advantage, thus getting rid of the poor hay and making a saving of the good. — *The People.*

Mark Twain on Agriculture.—The proprietors of the *Galaxy* have engaged Mark Twain to conduct a new department in that magazine, and he has selected that of *Agriculture*. In a letter to the editor, he says, "I have no practical knowledge of Agriculture, but that need not interfere. You may have noticed that the less I know about a subject, the more confidence I have." There are other writers on agriculture in the papers who have precisely the same qualifications for the work, but who are by no means so candid in stating the fact as our jocose friend Mark has been.

Boston Journal of Chemistry.
BOSTON, MAY 1, 1870.

PROSPECTUS.

VOLUME V. of the JOURNAL, commencing July 1, 1870, will be increased in size, each number containing not less than *twelve pages* of reading matter. It will be printed from stereotype plates, on the finest book-paper; and we shall continue to make it the *best and cheapest scientific journal in the world.*

The terms for the JOURNAL *will be one dollar per year; single numbers, ten cents.*

The JOURNAL will be, as it has been, independent, unbiased, careful, and reliable. No individual, corporation, or organization is rich or influential enough to suppress its opinions, or in any way control its influence. It will continue to expose frauds, schemes, and speculations, which profess to originate in or grow out of progress in science and art. The great and growing evil of *adulterations* in articles of food, medicine, fertilizers, and substances used in the arts, will receive special attention, and the nature of the sophistications and adulterations will be fully exposed. We shall present numerous useful practical formulæ, recipes, and scientific suggestions, which alone will be worth many times the price of the publication.

TO PHYSICIANS,

It will continue to be of *special service*, as it will keep them informed of the nature of all new remedial agents, all new discoveries in chemical and medical science, all new principles or processes connected with toxicology and pharmacy.

TO DRUGGISTS,

It will come as a reliable friend and adviser, affording information and instruction upon all matters relating to the manufacture and dispensing of medicines, and the other substances and agents produced or vended by them.

TO FARMERS,

It will impart information upon the important subjects of the chemistry of plant-growths, and the nature and preparation of fertilizing agents.

TO CHEMISTS, MANUFACTURERS, ARTISTS, TEACHERS, STUDENTS, CLERGYMEN,

All intelligent readers, men and women, everywhere, the *Boston Journal of Chemistry* will supply information and instruction of the highest importance and value.

The JOURNAL has, at the present time, a large army of friends, and these we ask to aid us in extending its circulation. Our patrons know how instructive and useful it *has been* in the past: we assure them it will be even *better* in the future. Cannot each one send us a new subscriber, to commence with Vol. V.?

We make this offer to *new subscribers*: All those who subscribe, and send us *one dollar* in advance, will receive the remaining numbers of Vol. IV. They will receive the whole of Vol. V., and all the numbers of Vol. IV. which are issued, after January 1, 1870. *Subscribe early*, and thus obtain one-half of Vol. IV. as a gratuity.

PREMIUMS.

To any person who will send us the name of one new subscriber, with $1.00, we will send a fine mezzotint *carte de visite* photograph of the late George Peabody. For two new subscribers, with $2.00, a *cabinet* size photograph of the late George Peabody. For three, with $3.00, one copy of the JOURNAL free for one year, or a Petite Microscope. For five, with $5.00, a set of twenty carpenter's tools in a hollow handle. For six, with $6.00, one copy of Dr. Nichols' Chemistry of the Farm and the Sea; Rolfe and Gillet's Hand-book of the Stars, Hand-book of Chemistry, or Chemistry and Electricity; or the Nursery Magazine. For ten, with $10.00, one copy of Dr. Lord's Ancient States and Empires; or Oliver Optic's Magazine; Our Young Folks; or, The Riverside Magazine. For twelve, with $12.00, Tilton's Horticultural Magazine. For sixteen, with $16.00, one copy for one year of either of the four dollar Magazines mentioned in the list following; or a * Boy's Tool Chest, thirteen inches long, eight inches wide, and eight inches high, with a complete set of Carpenter's tools, saw, plane, etc. For twenty, with $20.00, the N. Y. Journal of Psychology, or the Philadelphia Medical and Surgical Reporter. For twenty-five, with $25.00, a fine * Set of Croquet implements. For eighty, with $80.00, a * Complete set of Chemical Apparatus, suitable for all the experiments described in Rolfe and Gillet's Hand-book of Chemistry. For one hundred, with $100.00, one * Cutter Clinical Microscope; or, a fine * Waltham Watch, in a silver case.

In all the cases mentioned above, we give to each new subscriber the JOURNAL from January, 1870, to July, 1871, or *eighteen* papers for the price of *one year's subscription*. This is exclusive of the premium to the getter-up of the Club.

☞ Premiums are allowed only upon *new* subscribers, not on renewal of subscription by old subscribers.

* The express charges upon these articles to be paid by the receiver.

J. R. NICHOLS & CO., Publishers,
BOSTON.

THE JOURNAL GIVEN AWAY.

ON receipt of the publisher's price of any one of the following periodicals, we will send *both the* JOURNAL *and that periodical* for one year. This offer applies to those persons only who are not already subscribers to either.

ECLECTIC	$5.00
EVERY SATURDAY	5.00
NATION	5.00
N. Y. JOURNAL OF PSYCHOLOGY	5.00
PHILA. MEDICAL AND SURGICAL REPORTER	5.00
PUTNAM'S MAGAZINE	5.00
AMERICAN NATURALIST	4.00
APPLETON'S JOURNAL	4.00
ATLANTIC	4.00
COLLEGE COURANT (*New Haven*)	4.00
GALAXY	4.00
HARPER'S MONTHLY, WEEKLY, *or* BAZAR (*each*)	4.00
LIPPINCOTT'S MAGAZINE	4.00
N. Y. MEDICAL JOURNAL	4.00
OLD AND NEW	4.00
SUNDAY MAGAZINE	2.50
HOURS AT HOME	3.00
TILTON'S HORTICULTURAL MAGAZINE	3.00

GOOD WORDS FOR THE YOUNG	2.50
OUR YOUNG FOLKS	2.50
OLIVER OPTIC'S MAGAZINE	2.50

THE SOUTH.

WE spent a large part of the month of March in travelling through some of the Southern States, — Virginia, North and South Carolina, Georgia, etc. It was our first visit to this section, and the trip was full of interest. We left home to recuperate exhausted energies, and to avoid the chilling winds of March; but we have to declare that we suffered more from cold in South Carolina than we ever did in the frosty Bay State. March was a cold, disagreeable month in all parts of the South, and the poor invalids from the North must have suffered intensely. We came back, questioning more seriously than ever the wisdom of sending consumptives away from comfortable homes, at any stage of the disease. At present, it is impossible to procure proper food and home comforts, at any of the so-called sanitary retreats in the Southern States. Every place is crowded with visitors, of whom a large number are strong, lusty men and women, travelling for pleasure and to spend money. They secure the best seats in the railway cars, and the best rooms at the hotels; and weak invalids, unless accompanied by strong friends, stand a poor chance of securing needed comforts. The people of the South are kind, attentive and obliging, and do all they can to render the visits of Northern men and women agreeable. Not the slightest revengeful feeling or petulant humor did we discover in any individual, and we believe there is as good order and as much kindly feeling existing in the Southern States as in any section of the country. In agriculture, commerce, and the mechanic arts, a glorious future is opening to the South. The colored population, as a general thing, are living upon the best of terms with their former masters, and are cheerfully aiding in developing the resources of the country. We were pained, however, to learn that disease is making sad havoc among them. Pneumonia, in the acute form, is sweeping away thousands every month, in Georgia and the Carolinas. One planter, who employs nearly four hundred, informed us that ten per cent of them had died from this disease since Christmas. They are naturally improvident and careless, and being obliged to assume the responsibility of looking out for themselves, they suffer from insufficient food, and exposures. The white people do all they can to aid them, but, after all, it is but little that they can do. The millions of acres of unimproved lands in the South must, before many decades have passed, be brought under cultivation, and the enormous exportation of cotton, rice, cereal grains, and tobacco, will turn the golden currents, flowing in the track of commerce, towards our shores, and render us the richest nation under the whole heavens.

CINCHO-QUININE.

WE notice that Mr. W. T. Wenzel, druggist, of San Francisco, publishes a paper upon Cincho-Quinine in the April number of the *Pacific Medical and Surgical Journal*, which purports to have been read before the California Pharmaceutical Society. In this communication Mr. W. states that, upon analysis of the article, he is unable to find in it quinia, quinidia, or cinchonidia, but he does find quinicia, cinchonicia, and cinchona. Of course, we do not know whether the gentleman had in hand the article as prepared by us, or that of some other maker, of whom possibly there may be a dozen. If the specimen was the product of our laboratory, the value of his extraordinary analytical skill may be understood from the fact that the article *did* contain all the alkaloidal principles he was unable to find, and but mere traces, scarcely enough for detection by the most delicate tests, of two of those which he alleges he found. Of quinidia alone we think no specimen has ever left our laboratory containing less than four or five per cent, and also all the other alkaloidal principles found in Loxa bark.

The analysis of a body made up of such complex and delicate organic principles as are found in barks, is an exceedingly difficult labor, and the tests and reactions, involving deceptive color-tints or forms of crystals, are so fallacious and unreliable, that competent, experienced chemists are careful in expressing positive opinions regarding the results of such investigations.

We supply cincho-quinine at wholesale, at about *one half* the price of sulphate of quinine, and the bark alkaloids are in their naked alkaloidal condition, not presented as sulphates. The article, during the past two years, has been used in all parts of the country, probably by not less than *three thousand physicians*, in quantities from one ounce to forty or fifty by each, and a majority of these have kindly communicated to us the results of the trials.

The testimony in its favor is nearly unanimous. Physicians state, that cincho-quinine being almost tasteless, and so much cheaper than sulphate of quinine, and equally efficacious, it is preferable to that salt. This is the language employed by the distinguished medical gentlemen who have given it careful and extended trial.

Referring again to the author of the communication which has called forth these remarks, we venture to suggest that it is quite possible his analytical labors have not been so entirely *disinterested* as he would have us believe them to be.

A little gratuitous advertising through the Medical Journals may not be distasteful to him or detrimental to his interest as druggist and manufacturer of "*non-officinal remedies and pharmaceutical novelties.*" We learn from an advertisement which appears in the *Pacific Medical and Surgical Journal*, that among the "pharmaceutical novelties" he manufactures, are "*Elixir Calisaya,*" and "*Sucro Gaduoleine.*" What the latter medical compound is we are not informed, and we would suggest to the gentleman, that at the next meeting of the California Pharmaceutical Society he present an elaborate "analysis" of this strange nostrum.

POPULAR BOOKS ON SCIENCE.

There are those who are disposed to sneer at popular books on science, because they are, at best, mere compilations from the materials given in larger and more elaborate works. If this work of compilation is badly done; if, through haste or ignorance, those "half truths," which are virtually *whole lies*, are the result of the attempt to abridge or simplify the original matter, there is good ground for this criticism; but if the work is honestly and ably done, scientific men should welcome it rather than discourage it. In a review of one of these books in "*Nature*," Rev. Charles Kingsley has the following very sensible remarks on this point:—

"In this age of *specialization*, when each minute branch of physical science requires a lifetime of research, how are the many unscientific to be taught the vastness and beauty of nature, save by those who take the results of other men's labor and cast them together into a shape which the many will care to look at? Provided they do not actually steal, allow them to borrow as freely as they will. What they borrow from the scientific writer, they will repay him a hundredfold, in the form of pupils, readers, and enlightened public opinion. Meanwhile, those who wish well to the cause of truth, may trust that by every book of this kind one more human being will be wakened to the magnificence as well as the importance of facts; one more will be saved from the ancient empire of unreason; one more will be inclined to give rational glory to God, as he discovers how glorious his works are, even in the minutest polyp; and one schoolboy, it may be, or even undergraduate, seeing this book in his sister's hands, while he is at home for a vacation, will be led to inquire (not without reason), why he also is not taught something about these strange and beautiful works of God, and something of the science which investigates them, instead of the mispronounced Latin and Greek, in learning which (and most imperfectly) he spends the ten or twelve golden years of youth."

In this country, schoolboys are more generally taught the elements of physical science than in England (though, in the majority of cases, unfortunately, both the text-books and the teaching are wretched), and even in our colleges, the absolute despotism of the dead languages is declining, and the claims of science to an honorable place in the course of study are beginning to be recognized. But the entire scientific education of the masses of the people must long continue to be gained, as it has been, from these books prepared for general reading, and from periodicals (among which we consider it an honor to have our own reckoned) devoted to the dissemination of scientific knowledge in a form which shall be popular in the best sense of the word,—accurate without being too technical, simple without being puerile, entertaining without being "sensational."

PHYSICAL SCIENCE AT HEIDELBERG.

In some respects the facilities for the study of physical science at the University of Heidelberg are superior even to those at Berlin and Göttingen. The *Physical Laboratory* is under the supervision of Kirchhoff, who lectures weekly, with experiments, on a given subject. The following week each student in the laboratory goes through the experiments for himself, and this constitutes the main feature of the course. For several days in the week the students can also conduct researches of their own.

The *Chemical School*, under the management of Bunsen, has added even to its former renown. In no other European laboratory, except that of Liebig, at Giessen, have so many first-class scientific chemists been trained. Prof. Roscoe says, that among those who studied with him at Heidelberg, were "men who are now making rising reputations in most of the German universities, or in the various institutions of France, Russia, Portugal, Great Britain, and America." In Germany (unlike this country, where a knowledge of the drug business is not deemed necessary for keeping an apothecary shop and dispensing medicines), all druggists and pharmacists are compelled to attend a regular university course in chemistry, and many of the students at Heidelberg belong to this class.

Besides these two departments, the University has yet another, devoted to physical science,—the *Physiological Laboratory*, conducted by Helmholtz. An ample and elegant building has lately been erected for the use of the Professors in Physics and Physiology, with lecture-rooms, laboratories, apparatus rooms, etc., and also dwelling-houses for the professors.

With these three departments, under the direction of three men so renowned as Kirchhoff, Bunsen, and Helmholtz, we can hardly wonder that Heidelberg is attracting the very *élite* of the whole world's pupils in physical science.

The Journal.—The new volume of the Journal commencing in July, will embrace improvements which we are confident will be pleasing to our large family of patrons and friends. A new head, new paper and type, with the enlargement to sixteen pages, will give the Journal an appearance which will be in keeping with its greatly extended influence and circulation. Not a patron has thus far signified his intention of withdrawing from us in consequence of the necessary increase in price. On the contrary, our list is increasing at an unusual rate, and we have every evidence that the proposed improvements will result greatly to the advantage of the paper. Friends, and old subscribers, send in the names! We have no canvassers but you, and to you we look for aid in extending the circulation and consequent usefulness of the Journal.

Correspondence.—A large number of letters addressed to the editor of the Journal remain unanswered, as it is impossible to respond, owing to want of time and strength. Our friends must remember that our duties are very exacting and multifarious. Beside the care of the Journal, we have extensive chemical manufacturing interests to look after; also, our farm in the country, experimental researches to make, lectures and reports to prepare, and important trusts, both public and private, to attend to. These tax our weakened energies to the utmost, and render it impossible to answer or even read letters soliciting advice or assistance upon matters connected with agriculture, chemistry, or the industrial arts. Many letters, even from personal friends who have good claims upon our attention, we are obliged to neglect. All correspondence relating to business matters which our assistants can manage will be promptly attended to.

The Air Furnace.—Owing to the displacement of the sketches of the new air furnace alluded to in the last number of the Journal, our engraver has not been able to have the cuts ready for this number. They will appear in our next. Our experiments upon furnaces have created a wide-spread interest among both users and manufacturers, and we hope great good will result from the investigations. Many letters have been received from various parts of the country, in which the writers solicit an interest in the "patent" of our new device. We would say to such correspondents, and all others, that we have no patents to dispose of. The experiments were made with the view of conferring benefits upon the public, not for the advancement of private interests. If the improvements made in furnaces are useful and important, as we know them to be, they are open to all, without money and without price. We are desirous that the manufacture shall be in competent and reliable hands, and that the price shall be fair and equitable; but further than this we have no interest.

EDITORIAL NOTES.

Trusting Nature.—We often hear of trusting Nature in disease, but, as a recent writer very sensibly says, "before trusting Nature, and proceeding to help her, it would be well to inquire whether she intends to cure the patient, or to put him into his coffin. For myself, I greatly mistrust her, and would wish to ask, previous to assisting her, whether she is really my mother, or only my step-mother." There are many popular expressions which turn out to be nonsense when we look at them closely. Most of the proverbs which are often quoted as if they were infallible utterances, are directly contradicted by other proverbs equally in repute as oracles of pithy wisdom. "Look before you leap"; but, "nothing venture, nothing have." The "rolling stone gathers no moss"; but, "the sitting hen never grows fat." And so with scores of these "wise saws," which, instead of being universally true, are partial and one-sided, and consequently often false.

A Startling Discovery.—One of our Boston papers lately remarked, concerning the electric light: "It is exceedingly brilliant, and science has developed the fact that it is entirely different from the calcium light, and may be used with perfect safety." It is gratifying to know that these two modes of illumination have at last been proved to be different. We hope no scientific man will hereafter make the mistake of considering them identical. Speaking of lights, science has *also* "developed the fact," that a tallow candle is entirely different from bad kerosene, and may be used with perfect safety, while the latter cannot. The *savant* who has just announced this discovery, will resume his chemical investigations after a brief vacation,—rendered necessary by the exhausting nature of his recent labors,—and he does not despair of eventually demonstrating that chalk and cheese are distinct chemical compounds.

The Winter Weather.—The mean temperature of the three winter months, according to the accurate meteorological record kept by Prof. Loomis, at New Haven, was only 1.7° above the average. The small amount of ice which formed during the winter might be supposed to indicate a much higher average temperature; but, as Prof. L. remarks, "the apparent discrepancy is explained by the fact that the coldest weather of the past winter occurred early in December, but was not of sufficient duration to form ice of great thickness. Then followed seven weeks of unusually mild weather, during which the ice of December generally disappeared. The month of February has been as cold as usual, but this was insufficient to make entirely new ice of great thickness."

The *average* temperature of December was a fraction of a degree *below* the average of the past ninety years; but the first half of the month was unusually cold, the last half unusually mild. There was nothing very

remarkable in the *mean* temperature of January, compared with several other seasons in the course of the last twenty years, though it was above the average. February, like December, was a fraction of a degree *below* the average of the ninety years.

The amount of rain and melted snow at New Haven, was 13.18 inches for the three months, or 20 per cent greater than the average for that place.

MEDICAL WITNESSES.—In a recent suit in England, Dr. Rumsey, of Cheltenham, while testifying as to the condition of the defendant at a certain time, said, in answer to a question from the attorney, "I am here to give evidence as to facts, not to state opinions." The *Lancet* commends him, and adds:—

"A subpœna does not require a witness to state opinions. Medical practitioners who are so unfortunate as to be mixed up with the parties to a lawsuit, cannot too well remember that any evidence that they give may, if it so please them, be strictly limited to a narration of facts observed."

THE OLDEST INHABITANT.—The most venerable relic of humanity extant is the skeleton of one of the earlier Pharaohs, encased in its original burial robes, and in a good state of preservation. It was added to the treasures of the British Museum a year and a half ago. The lid of the coffin that contains this regal mummy bears an inscription which shows him to have been the Pharaoh who succeeded the heir of the builder of the Great Pyramid, about a thousand years before Christ, or before the birth of Solomon.

HIGH LIVING.—According to a foreign scientific periodical, the highest inhabited spot on the globe is the hamlet of Antisana, in Peru, 4,101 metres above the level of the sea. Another authority gives the height as 13,455 English feet, which is very nearly the same. The boiling point of water at this elevation is 187° F., which must interfere seriously with its use for some culinary purposes. The highest inhabited point in Europe, according to the same authority, is the Hospice of St. Gothard, 2,075 metres above the sea (6,867 feet, as given by Baedeker); but this must be an error. The inn on the Furca Pass is 7,911 feet above the sea, and the Hospice of the Great St. Bernard is 8,999, as Baedeker states it, and 8,200 or more feet, according to other authorities. This is probably the highest point in Europe which is inhabited throughout the year. At the summit of the St. Theodule Pass, in Switzerland, 10,899 feet above the sea, there is a little inn where a couple of men live during the summer months, to furnish entertainment to the numerous travellers who cross the pass.

CHEMICAL MAGIC.—Not many weeks ago, in Berlin, Madame A. W. Hofmann gave a grand entertainment and ball to a large company of her eminent husband's pupils. In the ball-room there were placed on a table a great number of bouquets of flowers (artificial, of course), all snow-white, and also many pieces of white silk ribbon; at the other end of the room a fountain was arranged, throwing, from narrow openings, jets of *eau de Cologne*. The bouquets were taken by the ladies, and the ribbons by the gentlemen; and, while waltzing together, and thus arriving at the end of the room where the fountain played, the ladies, holding their bouquets to be sprinkled with the perfume, beheld the white flowers become suddenly beautifully red, violet, blue and yellow, while the ribbons carried by the gentlemen, assumed, under the same influence, similar colors. The secret of this trick is simply that the flowers and ribbons had been very gently dusted over with the dry powders of various aniline colors, and, on becoming moistened by the eau de Cologne (alcohol), these powders became dissolved, and imparted colors to the objects.

ETHEREAL INEBRIATION.—It appears that methylated ether is extensively used instead of whiskey in the counties of Londonderry, Antrim, and Tyrone, in Ireland. Topers take doses of from two to four drams, from twice to six times a day. A Mr. Draper has published a pamphlet in which he deplores the injury thus done to the Inland Revenue, and to the Fire Insurance Companies; the former suffering from the loss of nearly $30,000 a year in the tax on whiskey (the ether pays no tax), and the latter from the increased risk of fire due to the free use of a very inflammable liquid by ignorant and drunken people.

Speaking of ether, it is a curious fact that the sensitive plant is paralyzed by its vapor.

JAPAN GIVING LESSONS TO FRANCE.—A French translation of a Japanese work on the rearing of silkworms has just appeared in Paris. It is published "by the order of his Excellency, the Minister of Agriculture." It is said to be the first French translation of a Japanese book.

OZONE AND EXPLOSIVES.—It is a singular fact of recent discovery, that nitro-glycerine, dynamite, iodide of nitrogen, chloride of nitrogen, and some other similar compounds, explode the moment they are brought in contact with ozone. The experiment may be tried by putting a drop of nitro-glycerine into a jar containing ozone. Ordinary gunpowder and picrate of potash gunpowder are very slowly decomposed by ozone.

NITRIC ACID FOUND IN THUNDER STORMS.—When the spark of the great induction coil at the "Royal Polytechnic" is passed through air, and the air is blown against damp litmus paper, a red coloration is produced. In order to ascertain whether the acid was nitric acid, air through which the spark was passed was drawn through distilled water. Nitric acid was thus obtained in large quantities, showing that the popular notion that this compound is always formed in thunderstorms is well founded. This fact, moreover, proves that a thunderstorm, as has been generally believed, tends to purify the air.

TO DETECT ADULTERATIONS IN CANDY.—A number of the wholesale candy-makers in New York, have united in recommending the following as a simple means of detecting falsifications in confectionery:—

"Any person may analyze lozenges, opaque candy, or sugar plums, by simply dissolving in water. If the water remains transparent, the candy is pure; but if milky or depositing a sediment, terra-alba, or some equally harmful adulteration has been used."

That confectionery is extensively adulterated is a notorious fact. If any one doubts it, he has only to go to the wholesale dealers, who will give him their prices for both the pure and the impure article. Tons of terra-alba are daily devoured by unsuspicious lovers of sugar-plums.

BOSTON JOURNAL OF CHEMISTRY.—Dr. Nichols seems determined to make this the leading chemical journal of the country. We would commend it to the notice of our readers as every way worthy of their patronage. — *Phila. Med. and Surg. Rep.*

CHRONOLOGICAL FODDER.—It is said that Guizot has become dyspeptic from eating too many dates. A historian may be pardoned for taking to a diet of that sort, but it is unfortunate that he should stick to it so closely as to injure his digestion. Lowell, in his "Fable for Critics," speaks of a critic who was "fond as an Arab of *dates*."

LITERARY NOTES.

MESSRS. Lippincott & Co. have just published "*A Handbook of Operative Surgery*," by John H. Packard, M.D., of Philadelphia. The author has aimed "to produce a practical guide, omitting nothing which would be to the purpose, and introducing nothing foreign to it," and the plan has been faithfully carried out. The clearness and conciseness of his directions, in connection with the copious illustrations on steel and wood, furnish precisely what is wanted in a practical handbook. Though the volume is compact, it is at the same time comprehensive, giving a practical description of at least one good method for every surgical operation in general use at the present day. We commend it to the attention of our professional readers.

The name of Fresenius has become almost a synonyme for analytical chemistry, and we are glad to see the new edition of his "*Quantitative Chemical Analysis*," edited, from the last German and English editions, by Prof. S. W. Johnson, and just issued by Messrs. J. Wiley & Son of New York. It is not so much a reproduction as a "reconstruction" of the original work. It has been carefully condensed where it could be done by discarding what was superfluous or untrustworthy; and on the other hand, judiciously augmented by the introduction of much valuable matter from foreign and native sources. Bunsen's new methods of treating precipitates, and Dr. J. Lawrence Smith's admirable method of fluxing silicates for the estimation of alkalies, may serve as samples of these important additions. The whole work shows the hand of a man thoroughly up with the times, and perfectly at home in both the theory and the practice of his subject.

Prof. Johnson has used the old notation and nomenclature, not because he does not fully recognize the necessity of teaching the new, but because the old "is still, and must for a long time remain, a part of the vernacular of the physician, the apothecary, the metallurgist, and the manufacturer."

Dr. Hall's "*Health by Good Living*" has already reached a seventh edition. One of the leading medical magazines says of it:—

"Written for popular perusal, it is one of the few books of the kind we can conscientiously recommend. To our professional brethren who are afraid of 'a good square meal,' we especially commend it. It is full of good sense, and is professionally unexceptionable in tone."

"*The Bowdoin Scientific Review*" is the title of a new fortnightly journal, edited and published by Profs. Brackett and Goodale, of Bowdoin College, Brunswick, Maine. The four numbers already issued are excellent, both in matter and in mechanical execution. The price is only two dollars a year.

The first *Annual Report* of Dr. James E. Reeves, City Health Officer of Wheeling, West Va., is in many respects a model document. It gives in a pamphlet of fifty pages an account of the "physical and medical topography" of the city,—its geology, ethnography, and manufactures; the diet, drinks, and habits of the people; the churches, hospitals, prisons, and other public institutions; full vital statistics and related information, etc., etc. We wish that our limits permitted us to speak of it more at length.

Two more volumes of Scribner & Co.'s "Library of Wonders" have been published.—"*The Wonders of Glass-Making*" and "*The Sublime in Nature*." All the books in this series belong to that class of "popular books on science" which we have commended more at length in another part of this paper.

Medicine.

HYDRATE OF CHLORAL.

WHEN this new agent was first suggested by Liebreich, and the results of his experiments were presented to the medical world, we regarded it with no special interest, and doubted if it would attract more than the ephemeral attention usually bestowed upon therapeutical or chemical novelties. After careful examination, and trial of the agent, we have been compelled to modify our early views, and we do not now hesitate to express the opinion, that it is not equalled in importance by any medical discovery since the anæsthetical properties of ether and chloroform were made known. Pure hydrate of choral possesses medicinal properties of such positive and beneficent character, that we are prepared thus early in its history to predict for it a place in medicine, second in importance to no other agent. The numerous trials in Europe and in this country prove it to be a safe and reliable hypnotic, and that in this regard it supplies a want long felt by physicians. We have taken the chloral repeatedly in various quantities, and under ordinary and peculiar circumstances and conditions, and have carefully noted its effects upon the secretions, the digestive organs, the circulation, and the brain. Not the slightest derangements of an unpleasant nature have occurred, nor have any abnormal conditions been produced which would lead us to fear to use it freely and continuously when needed. In certain quantities, it invariably produces natural and refreshing sleep, which is followed by no cerebral or gastric disturbance. For years we have suffered from attacks of mental prostration, attended by most persistent insomnia. No agent within the domain of therapeutical chemistry, organic or inorganic, afforded us any essential relief, until the hydrate of chloral was submitted to trial. We certainly feel under the deepest obligations to the learned and ingenious Dr. Liebreich, for his researches upon this remarkable compound.

Now, above all things, let us *protect* this important remedy, since it is placed in our hands. It would be a misfortune to have it discarded or condemned by any physician, through the employment of an impure or imperfect article. During the past two months we have bestowed much attention upon its manufacture, and have learned that it demands more care and skill to produce it in its highest integrity, than is required in the manufacture of any other laboratory product. The action of dry chlorine gas upon alcohol is liable to result in the formation of a great number of curious and contaminating substances, and the slightest derangement or interruption of the process interferes with the production of chloral. The process is a long and tedious one, requiring constant and careful watching during several days and nights. The neglect of a careless attendant may cause chemical reactions which entirely change the nature of the product, and occasion the most serious losses. It is exceedingly difficult, or in fact impossible, to remove many of the deleterious substances liable to be formed along with chloral in the retorts used in its manufacture, and hence nearly or quite all the specimens of the agent, produced upon this side of the water, have proved upon analysis to be *very impure.* Most of the specimens of German production we have found to be of great purity and excellence. As regards tests, it is sufficient to say, that when to a few drops of concentrated solution of hydrate of chloral in a test tube, is added an equal quantity of caustic potassa, if a dark or brown tint is produced in the liquid, it must be rejected as impure.

The present scarcity and exceeding high cost of chloral will not long continue. It must be observed, however, that from the great care required to produce it in an absolutely pure state, the price can never be very low, unless new and cheaper methods of manufacture are discovered. We believe the new agent will be found to be of service in a large number of serious affections which come under the notice of physicians. Among the annoying or distressing illnesses which we have good reason to believe it will alleviate, is sea-sickness. It has not been tried in a sufficient number of instances to enable any one to speak positively upon this point, but we think those who are about going upon the water will do well to make trial of it.

There is so much that is interesting and important connected with the new agent, that we shall keep our medical readers informed of any new discoveries connected with it.

WHOOPING COUGH.

ACCORDING to both French and English authorities, this disease has been successfully treated by *hydrate of chloral.* Dr. Ferrand, in the *Bulletin de Thérapeutique*, states that he had three patients in one family, to whom, after trying various remedies in vain, he gave chloral in syrup — 2 grammes of the former to 150 of the latter, or 25 centigrammes of chloral to the spoonful. The first three days two spoonfuls were prescribed for each evening, were not regularly given, and only the tolerance of the medicine was established. Then three spoonfuls were prescribed and were regularly given, and there was an abrupt and favorable change. Instead of three or four attacks of coughing, with vomiting, in the course of each night, there was unbroken and refreshing sleep. In the morning, on awaking, there was an attack of the cough for a few days, which soon disappeared.

Dr. Adams, in the *Lancet*, says that he has used the same remedy in severe cases of the cough. For a child of about six years old, the dose is five grains in syrup and water, two or three times a day. If the cough be most distressing at night, a dose of six grains given only at bed-time will usually ensure a comparatively quiet night. In some cases, he has used the solution of the peroxide of hydrogen during the day, and a dose of hydrate of chloral at bed-time, with marked benefit.

Benzine is another new remedy for whooping cough. An Italian physician, Dr. Bottari, in *Lo Sperimentale*, says: 1. The inhalation of the gases developed in the process of purifying illuminating gas has a happy effect on whooping cough, provided that disease be free from complications. 2. It is probable that the effect is due to the benzine developed in the distillation from the coal. 3. Benzine may be administered in doses of from 10 to 20 drops a day in mucilage or syrup. It may be employed at the same time as a vapor diffused in the chamber of the patient. If the benzine be used in the first stage of whooping cough it appears to be inert; while the improvement is marked and rapid if the agent be resorted to after the first stage, provided there be no congestion of the respiratory organs.

A writer in the *Lancet* strongly recommends the application of a blister to the nape of the neck or the shoulders of the little sufferer. The *Cincinnati Lancet* asserts that the leaves of the chestnut tree are an infallible specific in the disease. An infusion of the leaves is made, by taking half an ounce of them to the pint of boiling water, adding enough white sugar to make it palatable. Give the child as much of this, cold, as he will take during the day and evening; he soon gets to like it, if it is given as a drink instead of cold water.

HAY FEVER.

DR. COOK, of Selma, Ohio, who has suffered for years from *hay fever*, has made the disease a special study, and reports the result of his investigations to the Medical Society of the County of New York. He is satisfied that the affection has nothing whatever to do with the cutting or curing of hay, but depends solely on the irritation of the mucous surfaces, produced by the pollen of the plant variously known as *tall ambrosia*, *bitter-weed*, *rag-weed*, *hog-weed*, etc. This plant is very abundant in the cultivated portions of the country, in our latitude. The flowers are yellow spikes, covered with a dense pollen, which is widely disseminated by the winds. Persons affected with the disease find relief by a trip to the seaside or the mountains, merely because they are removed from the cause, as the weed does not grow either in barren or in uncultivated districts.

His treatment is the following: Prior to the manifestation of a paroxysm, a weak solution of tannin in rain water is administered, by means of the nasal douche; or sometimes a weak solution of alum, in order to harden these membranes; but should an attack supervene, which manifests itself by violent sneezing, a free discharge of thin acrid mucus from the eyes and nose, with a sensation of suffocation, then he uses a weak solution of permanganate of potash (from 3 to 5 grs. of the salt to the ounce of water) as an abortive; should the patient be enervated, then tonics should be given in conjunction with the salt, as indications present themselves.

Under this regimen Dr. C. has found little or no difficulty in mastering this disease at any time, and often one application of the potassic permanganate is sufficient to relieve the suffering in a very few minutes.

LACTIC ACID IN CROUP.

DR. ADOLPH WEBER was led to try lactic acid in croup, on account of its power of dissolving fibrinous exudations; and it has proved an efficient remedy in every case, even the most severe.

The treatment consists in the local application of the remedy to the windpipe by means of inhalation. The patient is made to inhale a solution of lactic acid (fifteen to twenty drops in half an ounce of water) at first every half-hour, and afterwards, when the respiration improves, every hour or every two hours a solution of 10 to 15 drops in half an ounce of water.

The inhalation is discontinued as soon as the dyspnœa has subsided, and to promote expectoration camomile tea is exhibited.

In using the inhalation, care must be taken that the vapor does not affect the eyes or face.

With this treatment was conjoined the internal exhibition of carbonate of soda every half-hour, or every hour, which was thought to exert a beneficial effect upon the exudation.

THE DOCTOR IN THE NURSERY.

THE following excellent suggestions are from Vogel's *Practical Treatise on the Diseases of Children:* —

Now, as regards the conduct of the physician, the utmost patience and gentleness are indispensable in his intercourse with children. Those from one to three years old are always the most difficult to manage. Nurslings and children under one year are seldom very timid, and are easily quieted by some diverting noise. But older children often have an insurmountable shyness for every strange face. Such a child the physician must not approach immediately after entering the room;

he should at first ignore the child's presence altogether; should enter into a conversation with the parents or nurse, in a gentle voice, and finally gradually approach the child with some bright object, or with a piece of sugar. When at the bedside, the child should not be immediately uncovered, its abdomen felt and squeezed, and the physical examination instituted. Some questions suitable to its age are first put to it, its playthings are admired, or it is told of some new ones, and promised to be presented with them, etc., etc.; in short, it is necessary to be on friendly terms with the child before the undertaking of a regular, thorough examination can be thought of. In this manner, however, it is almost always possible to quickly gain the friendship of the child. If, with a friendship formed in this manner, a little seriousness and energy are allowed to be blended, much more authority will thereby be acquired in a moment over the child than the parents ever thought possible. Children, under such authority, allow themselves very quietly to be examined, readily lie down upon any side desired, take even the bitterest medicines without objection, and assist the medical examination in every manner possible. *Never, and under no circumstances, should the attempt be made* to bring an unruly child into obedience by harshness, by firmly holding it, and still less even by a slight blow. Such measures not only cause greater fear, and give rise to violent crying, but the physician will thereby only bring upon himself the aversion and even hatred of most narrow-minded parents, — the class that usually have boorish and unmanageable children. On the other hand, if the physician in such instances retains his equanimity and mild voice, the parents will feel most disgraced by the ill-breeding of their children. They then sometimes punish the child so severely that the physician, from a medical point of view, has to interfere, and then he will have gained an humble and submissive patient. In general, the principle will hold good that the more seriously sick the child is, all the more easily will it permit itself to be examined.

FORMULÆ.

Hunter's Red Drop. — Corrosive sublimate, 10 grs.; hydrochloric acid, 12 drops. Triturate in a glass mortar and add gradually one oz. comp. spt. lavender. Dose, ten drops 2 or 3 times a day. *It is said* this preparation will not salivate.

Pills of Camphor are best made by trituration with castor oil, adding a very small quantity of alcohol if the mass is disposed to crumble.

Camphor Ice. — Expressed oil of almonds and rose-water, each 1 pound. White wax and spermaceti, each 1 ounce. Camphor, 2 oz. Oil of rosemary, 1 dr. Melt together. Glycerine may be substituted in part for the oil and rose-water.

☞ The article upon "Agricultural Schools," published in the JOURNAL in February, has received the warm commendation of agriculturists in all parts of the country. *Hearth and Home*, edited by Donald G. Mitchell, Esq., copies a considerable portion of the article, with the following introductory remarks: —

"We clip the following very sensible remarks from that excellent monthly paper, the BOSTON JOURNAL OF CHEMISTRY. We shall return to the subject at some future day; meantime we indorse fully the homely and jocular, yet practical common-sense view which Dr. Nichols takes of the matter."

We hope the accomplished author of "My Farm at Edgewood" will give us his views upon Agricultural Education, as we are certain they will be sound and practical.

BOSTON JOURNAL OF CHEMISTRY.

DEVOTED TO CHEMISTRY AS APPLIED TO

Medicine, Agriculture, and the Arts.

EDITED BY JAS. R. NICHOLS, M.D.

VOL. IV.—No. 12. BOSTON, JUNE 1, 1870. ONE DOLLAR PER ANNUM, SINGLE NUMBERS TEN CENTS.

THE

Boston Journal of Chemistry

IS PUBLISHED UPON THE FIRST OF EACH MONTH, BY

JAS. R. NICHOLS & CO., 150 Congress St., Boston,

TERMS, ONE DOLLAR PER ANNUM, IN ADVANCE.

Contents.

☞ Subscribers will remember that the volumes of the *Journal* commence and end upon the 1st of *July*, not January.

RECEIPTS.—A receipted bill will be sent by return mail to any subscriber who will enclose with his subscription a three-cent postage stamp, for return postage.

A list of premiums is offered to those who obtain subscribers.

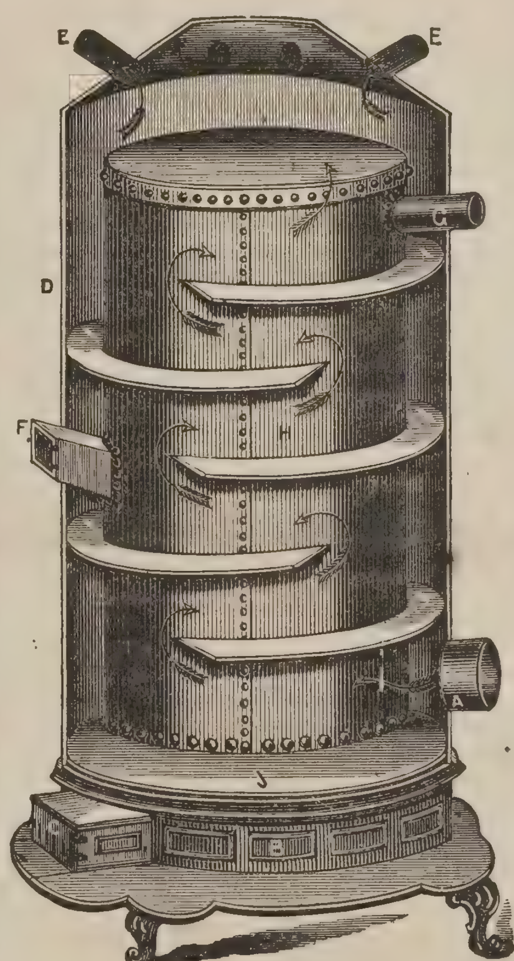
☞ Correspondents are particularly requested to give their names in full, with their Town and State; and in case of change of residence, requiring a corresponding change in the mailing of their papers, to give, not only the new address, but the old one also.

☞ We have no complete files of either Vols. 1, 2, or 3; of Vol. I. (originally issued bi-monthly), we have only Nos. 4, 5 and 6 (January, March and May, 1867); of Vol. II. (monthly), we have Nos. 2, 4, 5, 7, 8, 9, 10, 11 (August, October, November, 1867, January, February, March, April, and May, 1868); of Vol. III. we have all the numbers *except* 11 and 12 (May and June, 1869). All the other numbers are out of print, and it is impossible for us to furnish them.

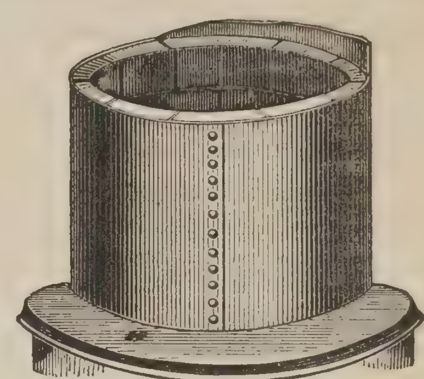
Of the numbers mentioned we have a few copies left, which we will forward to our friends, at the following prices, viz: Vol. I., three numbers, twenty-five cents; Vol. II., eight numbers, fifty cents; Vol. III., ten numbers, fifty cents. Vol. IV. has been stereotyped as issued, and we are able to furnish back numbers since July 1869, to any extent. Price, single copies, six cents; six copies for twenty-five cents.

Familiar Science.

THE IMPROVED AIR FURNACE.



THE cuts presented in connection with this article are intended to illustrate the interior arrangements of the portable air furnace, which we have been led to devise, with the view of obviating some of the objectionable features of those now in common use. It is very simple in construction, and although it presents but few changes in the forms of existing devices, yet these changes are radical, and modify completely the important working results. The heat-radiating surfaces are constructed *entirely of wrought or malleable iron*, securely riveted together, like the plates of a steam boiler, so as to be dust-tight and gas-tight. The important sanitary and other advantages of this method of construction have been fully discussed in former numbers of the JOURNAL. The air chamber is so arranged (forming a distinct compartment) that it is impossible for ashes or dust, except what may exist in the external atmosphere, to gain admission, and consequently the heated current flowing into the dwelling is pure and wholesome. The cold air entering the apparatus is compelled to pass over



every portion of the heated surface, and thus the radiated heat is fully utilized. The furnace ensures perfect cleanliness and freedom from obstructions in draft flue and air current, and derangements can hardly occur to vex, and endanger the health of the user. And further, there are no points where active oxidation or unusual wear can go on so as rapidly to destroy it. These are the distinguishing features, or points of excellence, found in the furnace. There are others, however, which are so obvious it is unnecessary to allude to them. Referring to the cuts: *A* is the pipe through which cold air enters the furnace; *B*, the ash chamber and grate; *C*, the ash-pit door; *D*, the external covering of galvanized iron; *I*, the series of annular metallic rings placed around the heat-radiating dome, to bring the air to every part of its surface; *F*, the feed orifice; *E*, the places of exit for the heated air; *G*, the smoke flue; *J*, the ring by which the air chamber is attached to the base. The small cut represents the fire-pot lined with fire-brick. The wrought-iron, riveted dome passes over this in close contact, and with the annular ring tightly riveted to it at the bottom, forms, in connection with the galvanized outside covering, the air chamber. The cuts do not show the grate, and some other working parts of the furnace. It will be observed that the air enters *above* the ash chamber and grate, and there is no possible connection between the ash and air chambers. No matter to what extent combustion is interfered with, or how violently the grate may be shaken, it is impossible for ashes or gas to pass into the air chamber, if the furnace is *faithfully* constructed. *Perfect construction* in this furnace is essential to its *perfect success.* No workmen but those who are honest, competent, and responsible should be allowed to attempt to construct it. The riveting of the plates is a matter which demands experience and skill, and is the point to which the most careful attention should be given. We presume that in most of the great cities and towns of the Northern and Western States, there are workmen competent to construct this furnace. It may be made of any size, and placed in brick if deemed desirable. The furnace which we had in use during the last winter was constructed under our own supervision, by a stove manufacturer, and its workings were most admirable. Its cost was less, it

consumed less fuel, than other furnaces of its size, and there was entire exemption from gas and dust, so destructive to health and comfort. In further explanation it should be said, that the base of the furnace is of cast-iron, and the doors are ground to a tight joint. The air to support combustion is admitted through a nicely adjusted slide valve, which may be controlled through the medium of a wire carried to the sitting-room or parlor above. The connection of the feed door and smoke flue with the wrought-iron, heat-radiating dome, *must be such as to admit of no possibility of leakage.* In the furnace we have constructed, the feed cylinder is tightly riveted on to the dome, and the connecting joint necessary for the door is placed *outside* of the air chamber. This insures perfect safety. Whenever a *competent, thoroughly reliable* manufacturer, in this city, or elsewhere, enters upon the construction of this furnace, we will give his name to our readers.

SHUT YOUR MOUTH.

Prof. Tyndall's researches on "Dust and Haze" continue to attract a great deal of attention, both in England and in this country. Scientific men are discussing them, and the popular press is making the most of the theme and its suggestions. The hygienic question of the hour is not what we shall eat or drink, but what —or rather *how* — we shall breathe. If the seeds of disease are everywhere floating in the air, and cannot be removed except by filtering it through fire or water, or some such substance as cotton wool, what is to be done? Shall we all put on "respirators," and go about like so many muzzled dogs? If the only alternative is death or that sort of disfigurement, all good-looking people at least will make their wills and resignedly await their doom. But fortunately we need not bandage our mouths with filters of cotton in order to escape the poison that lurks unseen in the air. Every man who has a nose has a natural "respirator" which is all-sufficient for ordinary purposes. The breath of life was breathed into man's *nostrils*, as we read in holy writ, and through his nostrils, and *not* through his *mouth*, it was intended that he should breathe. Some ten years ago, Catlin, of Indian notoriety, published a little book (it is still in print, we believe), entitled "*The Breath of Life*," which was a quaint but very sensible disquisition on the injurious effects of "mal-respiration,"—that is, mouth-respiration. It ought to be circulated as a sanitary tract, and just at this time it would be likely to be generally read. Its text, or motto, is "Shut your Mouth!" and, as the author urges, it ought to be inscribed "in every nursery and on every bedpost in the universe." It is unquestionably true that people who live and breathe according to this simple law are less liable to infectious diseases and pulmonary difficulties, than those who make the mouth the main organ of respiration. Catlin gives an account of a voyage he made between two South American ports, when thirty out of eighty passengers died of yellow fever. He says that careful observation satisfied him that, with scarcely an exception, the victims of the disease were those who habitually breathed through the mouth. In numerous other instances in which he was in the midst of yellow fever and cholera, he remarked the same general exemption from disease on the part of those who kept their noses open and their mouths shut. This is worth remembering, and our readers may be sure that, even if it does not benefit them, it certainly cannot harm them, to cultivate the habit of breathing through the nostrils, especially when exposed to a malarious or pestilential atmosphere. If, as Prof. Tyndall believes, ordinary air is never free from organic pollution, let us make fair trial of the nasal filters with which Nature has furnished us before we resort to any artificial contrivances for the same purpose. It will be both cheaper and more comely to shut the mouth than to muzzle it.

BEDS AND BEDDING FOR THE SICK

A few words in relation to bedding and bedsteads; and principally regarding patients who are entirely, or almost entirely, confined to their beds.

Feverishness is generally supposed to be a symptom of fever. Sometimes it is, but usually it is a symptom of *bedding*. The patient has had re-introduced into the body the emanations from himself which day after day and week after week have saturated his unaired bedding.

In looking out for an example in order to show what *not* to do, we should take the specimen of an ordinary bed in a private house: a wooden bedstead, two or even three mattresses piled up above the height of a table; with a valance attached to the frame. Nothing but a miracle could ever thoroughly dry or air such a bed and bedding. The patient must certainly alternate between cold damp after his bed is made, and warm damp before, both saturated with organic matter, and this from the time the mattresses are put under him until the time they are picked to pieces, if this is ever done.

If you consider that an adult in health exhales by the lungs and skin, in the twenty-four hours, three pints at least of moisture, loaded with organic matter ready to enter into putrefaction; that the quantity in sickness is often greatly increased, the quality is always more noxious—just ask yourself next where does all this moisture go to? Chiefly into the bedding, because it cannot go *anywhere else.* It *stays* there, because, with the exception of a weekly change of sheets, scarcely any other airing is attempted. A nurse will be careful to fidgetiness about airing the *clean* sheets from clean *damp*, but airing the *used* sheets from *noxious* damp will never even occur to her. Besides this, the most dangerous effluvia we know of are from the excreta of the sick. These are placed, at least temporarily, where they must throw their effluvia into the under side of the bed, and the space under the bed is never aired: it cannot be, with our arrangements. Must not such a bed be *always* saturated, and be always the means of *introducing again* into the body of the unfortunate patient who lies in it, that poisonous matter which nature is trying to *get out* of the system?

If a bed is higher than a sofa, the patient often prefers not to get out at all, rather than undergo the fatigue of getting out. If the bed were a low one, he might often feel like taking a few minutes' exercise every day in another room, or even in the open air. It is so very odd that people never think of this, or of how many *more* times a patient who is in bed for twenty-four hours is obliged to get in and out of bed than they are, who only get into bed and out of bed perhaps once during the twenty-four hours.

A patient's bed should always be in the lightest spot in the room: and he should be able to see out of a window.

It is scarcely necessary to say that the old four-post bed with curtains is utterly inadmissible, whether for the sick or for the well. Hospital bedsteads are in many respects very much better than private ones.

There is reason to believe that not a few of the cases apparently resembling scrofula among children, proceed from the habit of sleeping with the head under the bed-clothes, and so inhaling air already breathed, which is further contaminated by exhalations from the skin. Patients are sometimes given to a similar habit, and it often happens that the bed-clothes are so disposed that the patient must necessarily breathe air more or less poisoned by exhalations from his skin. A good nurse will be careful to attend to this. It is an important part, so to speak, of ventilation.

It may be worth while to remark, that where there is any danger of bed-sores, a blanket should never be placed *under* the patient. It retains damp, and acts like a poultice.

Never use anything but light blankets as bed covering for the sick. The heavy cotton impervious counterpane is bad, for the very reason that it keeps *in* the emanations from the sick person, while the blanket allows them to pass through. Weak patients are invariably distressed by a great *weight* of bed-clothes, which often prevents their getting any sound sleep whatever.

One word about pillows. Every weak patient, be his illness what it may, suffers more or less from difficulty in *breathing.* To take the weight of the body *off* the poor chest, which at best is hardly up to its work, ought therefore to be the object of the nurse in arranging his pillows. Now what does she do, and what are the consequences? She piles the pillows one upon the other like a wall of bricks, the head is thrown upon the chest, and the shoulders are pushed forward, so as not to allow the lungs room to *expand.* The pillows, in fact, lean upon the patient, not the patient upon the pillows. It is impossible to give a rule for this, because it must vary with the figure of the patient. Tall patients suffer much more than short ones, because of the drag of the long limbs upon the waist. But the object is to *support*, with the pillows, the back below the breathing apparatus, and above the hips; so as to allow the shoulders room to fall back, and to support the head, without throwing it *forward.* The suffering of exhausted patients is greatly increased by neglect of these points. And many an invalid, too weak to drag about his pillows himself, slips his book or anything at hand behind the lower part of his back to support it.

HOUSEHOLD HINTS.

To Renovate Black Silk.—Rub the silk all over on the right side with a solution of carbonate of ammonia and water (two teaspoonfuls powdered to a quarter of a pint of warm water), and smooth it on the wrong side with a moderately hot iron, and the silk will regain a bright appearance.

Substitute for Washing Soda.—For washing delicate fabrics the hyposulphite of soda is much better than common soda. It does not attack the skin of the hands, nor the articles to be washed, while it is an effective bleaching agent, and removes many kinds of spots better than anything else that can be used. It is now manufactured on a large scale for photographic purposes, and is quite cheap.

Waterproofing Cloth.—A writer in the London *Illustrated Times*, who has tested the method of waterproofing with sugar of lead and alum, as given in our last number, says that he has worn garments of common Scotch tweed thus treated, in the wildest storms of wind and rain, without getting wet. Even after walking in a driving rain for nine miles, his clothes were as dry under his waterproof overcoat as when he put them

on. He advises soaking the cloth in the liquid for twenty-four hours, and then hanging it up to dry without wringing.

A Cheap Filter. — The *Manufacturer and Builder* gives the following directions for a simple filter to purify cistern water: Place on the perforated bottom of a box a piece of flannel, and on this some coarsely powdered charcoal, then coarse river sand, and cover the whole with sandstone broken into small pieces.

Glazing for Linen. — To every quart of starch add a teaspoonful of salt, and one of white soap scraped fine. Boil the starch (after adding hot water) until it is of the proper thickness.

Salt in Cooking Vegetables. — If one portion of a dish of vegetables be boiled in pure water, and the other in water to which a little salt has been added, the latter will be found better flavored and more tender; if potatoes, they will be mealier. Onions are especially improved by being cooked in salt water. Their rankness of odor and flavor is mitigated, or modified into a peculiar sweetness and aroma. The salt appears to hinder the evaporation of the more volatile principles of the vegetables.

White Wash that will not rub off. — Mix up half a pailful of lime and water; take half a pint of flour and make a starch of it, and pour it into the whitewash while hot. Stir it well, and make it ready for use.

THE ORIGIN OF THE ELECTRIC TELEGRAPH.

In 1831, and part of 1832, the writer, then studying in the schools of the world-renowned Paris, had his lodging in the modest upper chamber of the unpretending "Hotel de Calcutta," in the "Rue de Savoy," near the famous old "Pont Neuf," on the students' side of the Seine, in the "Pays Latin." At the same time there lived in the same hotel another young compatriot, also engaged in the prosecution of his studies. His calling led him into very different places from those frequented by the writer, but on Sundays and holidays a visit to the Louvre often found the latter standing, in rapt admiration, before an immense canvas, reached by a stage eight or ten feet in height, upon which the former was daily engaged in copying the great picture of the "Shipwreck," which, at that day, graced (and perhaps still graces) the wall of the first room of the grand gallery of the Louvre. Time passed on, and, as the picture advanced to completion, and the artist grew in reputation, his friends augured most favorably for the future fame of one whose first finished piece produced him (rumor said) the handsome sum of *one thousand dollars*.

In the summer of 1832, this artist was on his way home in one of the fine ships of the Havre and New York line. Steam did not, in those days, puff the traveller on his homeward path across the grand Atlantic in seven or eight days, and adverse winds not infrequently protracted the voyage far beyond the endurance of impatient absentees, longing for home, for fame, and for fortune. The voyage, on this occasion, was unusually long. The passengers had used every ordinary resource by which they might hope to subtract an hour or two from the tedious time. All had been employed, all had been exhausted, all had failed.

At last a fellow-passenger, whose studies had also been going on in that grand old omnibus, Paris, and who, like the painter, was returning home with head and heart both filled, like his, with hopes of greatness, and the means of achieving it, and whose career has been hardly less successful, brought on deck his scientific apparatus, and proposed to lop off an hour or two from the tedious time by exhibiting experiments. Electricity and galvanism contributed their quota. In one of these experiments the effect produced was seen at a considerable distance from the instrument that was working. An Englishman, who was carelessly looking on, remarked, "What a pity we can't send messages as quick as that."

This remark seemed to pass away like the flash that had occasioned it, for no further reference was made to it, but it was a seed that had fallen on good ground, and in due time it sprang up and bore fruit millionfold.

Arrived at New York, the *ennuyé* passengers separated. But nothing was heard of the ambitious painter, whose copy of the "Shipwreck" had spread his fame ahead of him.

The old rope-walk that stood on or near the spot on which the distributing reservoir of the Croton water now is, was hired by some unknown person, who was engaged in some unknown experiments which did not seem to give much promise of useful result, since month after month and year after year passed by, and still the mysterious workman was as dark and mysterious as ever, and his barred doors still defied the curiosity of the curious, till at last even the mystery itself ceased to attract notice.

Ten years passed thus, and at the end of that time Morse emerged from his ropewalk with his telegraph accomplished, and electrified the world. — *Rural Carolinian.*

HABITATIONS FOR MEN.

There is nothing more disgraceful to the social life of this city (New York) than the homes we are in the habit of preparing for the poorer classes — and even for the middle class, for that matter. We complain of our streets, our markets, our wharves, and our public vehicles, and we complain justly, because they are below the standard of a third-rate city, anywhere; but worse than these are the tenement houses, put up for the accommodation of those of limited means. They are often scarcely fit receptacles for cattle. Many a horse, indeed, is stalled in a finer, cleaner, better-ventilated room than many a man. Thousands of families would be glad to exchange their cellars and garrets, where father, mother, and children are huddled together in a promiscuous and unwholesome squalor, — unwholesome morally as it is physically, — for the clean straw and warm blankets of our canine and equine favorites. Yet the men we condemn to these noisome retreats are not only our fellow-creatures, they are also our fellow-citizens, sharers in the government, voters who help to make the laws, and give character to our civilization.

It is the more shameful it should be so, because, with the same expenditure of money, but a little more compassion and care, lodging-houses could be made as comfortable as they are now repulsive. Let capitalists and builders build in flats or apartments properly arranged, as they do abroad, and let a janitor look properly after the police of them, and the most reckless and filthy housekeepers could soon be brought to desire and maintain agreeable and cleanly quarters. — *Putnam's Mag.*

Physical Constitution of the Sun. — To sum up the case, in respect to our knowledge of the physical constitution of the sun, we find that the seeming regularity and smoothness of the orb, and its homogeneous and quiescent condition, are mere illusions, arising from the immensity of the distance from which we view it. Its surface is, in fact, furrowed by enormous incandescent billows, and is in a state of incessant and violent commotion. Enormous flame-like coruscations, in masses larger than this globe, rise, and glow, and wave, and then melt away and disappear. Some of these blazing radiations appear to project themselves forty or fifty thousand miles into the surrounding space, though, on account of the immense magnitude of the body of the sun, and his vast distance from us, they do not perceptibly affect the smoothness of the contour of his disk, as it appears from the earth, to our unassisted vision; but the real violence and rapidity of the action thus taking place are inconceivable. On the one hand, cavities of absolute darkness, and on the other vast protuberances of extraordinary and special brightness, form and fluctuate over the surface, increasing and diminishing at the rate of thousands of miles in extent in very brief periods of time.

It is absolutely, though not relatively, as if the whole continent of America were to rise from the sea, in the midst of the most violent commotion, in the night, and then as suddenly melt away and disappear in the morning.

Thus the sun, instead of existing in the calm, placid, and unchanging condition which it appears to assume, is in reality a mass of seething and surging incandescence, deformed by incessant and tempestuous agitations of surface, produced by contests among forces the nature of which eludes our research as completely as the enormous magnitude and extent of their effects surpass our powers of conception. — *Harper's Magazine.*

Arts.

PARCHMENT.

There are certain manufactures of very ancient date in which there has been no material change even down to our day, and the making of parchment is one of them. Goatskin and sheepskin are preferred for the purpose; calfskin and lambskin being reserved for vellum, which is a finer quality of the same substance. The art consists in making the skin very thin and nearly transparent without destroying its firmness and strength. After the hides have been deprived of the hair and the flesh, they are immersed in a solution of alum and sea salt; they are then very quickly dried and stretched on wooden frames by means of screws, and drawn so tight that no wrinkle or fold remains. When the skin is very dry, the workman, with a sharp iron, takes off all the flesh which may still adhere to the inner surface. He then scrapes the outer surface to remove all dirt, taking great care not to injure the epidermis. The inner side is next *pounced;* that is, covered with a layer of very finely powdered lime, and rubbed with a large pumice-stone. The lime absorbs all the water yet retained in the skin. After this operation the skin is again dried, and is next handed over to the polisher, who repeats the process already described. The skin is thus made thinner and smoother. The final polish is given to it by means of a very soft pumice-stone. It is then folded, cut to the proper size, and pressed; after which it is ready for market.

Vellum, as we have said, is only a superior quality of parchment, and takes its name from the calfskin (the French for calf is *veau*, whence our *veal*) of which it is often made. The word *parchment* is a corruption of *Pergamena*, from Pergamos, where, according to Pliny, it was first made, some two hundred years before Christ. It was known, however, full three centuries earlier. Possibly the invention which Pliny mentions was merely an improved mode of preparing the material. The manufacture became a very important one in Rome about a century before Christ. All the world then used parchment for writing on, and this continued to be the case until the invention of paper from rags.

JOTTINGS.

Paper Fabrics. — In Japan, as we are told, the uses to which paper is put are almost innumerable, and we are beginning to emulate our Asiatic friends in that particular. Paper collars, of both the masculine and the feminine patterns, are now made by the million, and the same material is coming into use for other and more important articles of civilized apparel. A kind of paper has been invented which is very tough and flexible, and can be sewed with a machine, the seams being almost as strong as those of a woven fabric. Petticoats are made of this paper, which are either printed in imitation of certain fashionable styles of the day, or stamped out with open-work which in beauty and delicacy surpasses anything that can be elaborated by the needle. And these really exquisite productions can be retailed at fifteen cents each.

Chintz for bed furniture and curtains is also made of this new material, and likewise embossed table-cloths of very beautiful designs and finish. Imitation leather is another form into which it is put; this can be used for covering furniture, and even for shoes.

New Applications of Electricity. — We read in the papers of the day that certain experiments have

lately been made in heating cars by electricity. The axle of the car is to turn a magneto-electric apparatus, the current of which is to be converted into heat by a contrivance placed under each seat. The plan is indubitably a safe one, as the inventor claims, since the car can never be set on fire by it, even if thrown from the track; but that it cannot be an economical method of warming is obvious on the face of it. The heat obtained is heat from the fire in the engine *diminished* by the amount lost in its transmission through all the intervening machinery. The heat of the fire is converted into mechanical motion, which is converted into electricity, and this into heat again. This plan, however, is no more absurd than one devised in Russia, for which the inventor is said to have received a diamond ring from the Empress. A number of disks attached to the axle of the car are made to rub against surfaces arranged for the purpose, and the heat produced by the friction is to warm the car. As the warming is accomplished "without expense," it is evident that the friction caused by the disks must be of a kind not before known, involving no waste of power. In addition to the diamond ring, a leather medal should have been given to M. Berchau for the discovery of this new variety of friction. A leading London journal laments that this brilliant idea never occurred to an English engineer. We have no doubt that it will lament even more bitterly that it was a Yankee, and not an Englishman, that found out the method of displacing steam by electricity, which was recently described by the New York correspondent of the Boston *Journal*. "To run an engine of 20-horse power would require only a space of 3 feet long, 2 feet wide, and 2 high. The cost per day would be 35 cents. On a steamship no coal would be required, and the space now used for coal and machinery could be used for cargo. The stubborn resistance of electricity to mechanical use heretofore has, it is believed, been overcome. A continuous battery has been secured, and other difficulties removed, principally through the coil of the magnet. If the invention works as well on the large scale as it does on the machinery to which it is now applied, steamships will soon ply the ocean under the new propelling power. A machine of great capacity is being constructed, and will soon be on exhibition in New York. The whole thing, mighty enough to carry a Cunarder to Liverpool, can be secured in a small trunk."

It is unfortunate that the dawning resplendence of this mechanical millennium should be clouded even by a single *if;* but let us hope that this invention, which is evidently a "big thing" for a little one, will not disappoint the New York correspondent and the world when it comes to be tried "on the large scale."

The Oxygen Light versus Kerosene. — The *Insurance Monitor*, speaking of the new oxygen light, says: "We of the insurance fraternity — like the rest — are in search of 'more light' — of the right sort. We pay $2,000,000 per annum for the other kind. We should know our friends from our foes. Naphtha, under all its aliases and applications, is an emissary of the fire fiend, which finds quarter under an insurance policy just in proportion as underwriters are ignorant of its qualities. With pure oxygen we have no quarrel. If this enterprising company sends it around in hogsheads, as they threaten to do, and the hogsheads should leak, or Bridget should leave the bung open, we should only have, instead of an explosion, an improved atmosphere at a cost of $50 per thousand cubic feet for the improvement."

A New Dodge in Photography. — The *Photographisches Archiv*, of Berlin, states that negatives on ground glass give very soft and beautiful impressions. The glass must have rather a coarse grain, and the negative must be taken on the smooth side. The writer adds that the secret of this method is sold in America at high prices under the name of the "Berlin process."

USEFUL RECIPES.

To Make Water-Proof Blacking. — Take an old pair of India rubber shoes (boots or any old India rubber); cut them up and pull off the cloth lining; put the rubber in about a pint of neat's foot oil, and set it on the stove until the rubber is entirely melted, stirring it once in a while, and don't let it boil or burn. It will take about two days to melt the whole. As soon as the rubber is melted, stir in one-half pound of beef or mutton tallow, and one-half pound of beeswax. If it is not black enough, you may add a little lamp-black.

Now to apply it to the boots: wash them clean of mud and blacking; when they are nearly dry apply the water-proof all over them — if the weather is cold, work near the stove. The best thing to use in applying this blacking is one's hands, and considerable elbow grease to rub it well into the leather.

Any one using this application, and then having wet feet, had better give the boots away and buy a new pair, or send the old ones to a cobbler and have the seams attended to.

Isinglass Glue. — Dissolve isinglass in water, and strain it through coarse linen. Then add a little alcohol, and evaporate to such a consistency that when cold it will be dry and hard. This will be found to be more tenacious than common glue, and therefore preferable in many cases.

To "Green" Pickles without the Use of Copper. — Digest the fruit or vegetables for some time in boiling salt water. Then take them out and pour boiling hot vinegar over them. On the third day take them out of the vinegar, boil the latter, and again pour it over them while hot. It is said that this process, a few times repeated, will produce a dark green color, like that obtained by verdigris in the ordinary method of "greening," but of course not poisonous.

To Clean Engravings, etc. — It has been found that ozone bleaches paper perfectly without injuring the fibre in the least. It can be used for removing mildew and other stains from engravings that have been injured by hanging on the walls of damp rooms. The engraving should be carefully moistened and suspended in a large vessel partially filled with ozone. The ozone may be generated by putting pieces of clean phosphorus in the bottom of the vessel partially covered with water; or by passing electric sparks through the air in the vessel.

OXIDATION OF IRON USED IN BUILDING.

Iron has come to be extensively used in the walls of buildings, for the purpose of tying or bracing the masonry, and it has been taken for granted that in such positions it is practically indestructible. But a discovery recently made in England shows that the metal, when thus built into masonry, may not only rust, but also in the process of rusting act as a lever to pry apart the blocks of stone which it was intended to bind together. The following account from the London *Builder* is exceedingly interesting in a scientific point of view, and it ought to be carefully pondered by the architect: —

"The question of the mode in which iron suffers from oxidation, when included in masonry, appears likely to attract fresh attention. It is a subject on which those persons who are familiar with the repairs, or even with the demolition of old buildings, are not altogether without experience. But especial value attaches to the discoveries made on the recent occasion of the examination and repair of the tomb of King Henry VII., in Westminster Abbey, from the fact that both the date of erection, and the subsequent history of the monument, are so distinctly ascertained.

"After the cleaning of the statue of the Countess of Richmond, to which much public attention was directed, last May, the curators of the tombs proceeded to examine the central monument of the Abbey, that of King Henry VII. and his queen, standing, as is well known, in the chapel founded by that sovereign, under the protection of a richly wrought *grille*.

"Not only did the effigies appear to be coated and partially corroded in consequence of long neglect, but the altar tomb itself gave symptoms of dilapidation and decay. Joints yawned and cracks menaced, and the general appearance was such as is often produced, in similar structures, by subsidence of the foundations. The effigies were therefore carefully removed, and carried into the Eastern apse, or smaller chapel, where they were cleaned, and that with great science. The altar tomb itself was reverently taken to pieces, with a view to its replacement in its original integrity. It soon appeared that no subsidence had occurred. On the contrary, the tomb had been built on the finished pavement of the chapel, and the portion of this pavement which had thus been protected from wear was in a condition of great and original splendor, being enriched with a diapered pattern, partly polished, and partly pounced or frosted.

"The actual cause of the dilapidation of the tomb then appeared. It was nothing but the oxidation of the only pieces of iron which had been employed by the builders. All the fittings were of copper, with one exception. At each corner of the tomb, as many of our readers will remember, sits a boy angel, in gilded copper. To keep these figures in their place, copper bolts were employed, which passed through the upper portion of the ornamental work, and were secured by attachment to four plates of iron, which were built into the tomb itself under the slab on which the effigies rested. These four iron plates, notwithstanding their protection, first by the work of the tomb itself, and secondly by the building which sheltered the tomb from the chief vicissitudes of atmospheric temperature, had developed, on either side of each, solid plates of rust, of from three to four times the thickness of the orignal iron. The slow formation of this oxide had acted as an irresistible wedge, driving the fabric asunder, and threatening in course of time the entire overthrow of this noble monument.

"Specimens of these plates of oxide, as well as one of the original iron plates, were exhibited at the meeting of the Royal Archæological Institute, on the second of July last. The dangerous metal has now been replaced by plates of copper; and the tomb has been restored to its original beauty. But the lesson as to the conduct of iron when included in masonry or in mortar, even under circumstances which might be presumed to be more than ordinarily favorable, is not one of which any prudent architect or engineer will lose sight.

OLIVE OIL AND COTTON-SEED OIL.

The *Manufacturers' Review* states that immense quantities of partly bleached or "yellow" cotton-seed oil are now consumed in the adulteration of olive oil. Indeed, it is hard to find a pure olive oil in the market, except in first hands. If this were the whole story, we need not be particularly disturbed about it, for the cotton-seed oil is quite as palatable as the olive oil, and it is not improbable that, when people generally become more familiar with it, they will use it for culinary purposes, in preference to the latter. When cooled, moreover, it deposits a solid fat, which is quite equal to good sweet butter, and may hereafter prove a rival to that vaccine product.

But this is *not* the whole story of the adulteration to which we have referred. When a considerable proportion of the native oil is added to the imported article, the greenish tint of the latter is destroyed, and *stearate of copper* is added to restore it. This, like many of the salts of copper, is a poison, and so the sophisticated oil becomes more or less deleterious to health.

To test olive oil for this adulteration, take a small quantity of it, and add to it an excess of aqua ammonia; if it turns blue, the presence of copper is proved.

To test the oil for the admixture of the cotton-seed oil,

put a little of it in a test-tube, add a few drops of solution of nitrate of mercury, and shake it. If the oil is pure, it will become solid, so that it will not run out, even when the tube is inverted. The cotton-seed oil, treated in the same way, becomes only semi-solid. The thickness of a mixture of the two oils, when the nitrate is added, will depend upon the proportion in which they are mixed. If there is more than 10 per cent of the cotton-seed oil, the mixture will not become entirely solid.

Again, most vegetable oils, when shaken in a test-tube with a little sulphuric acid of the specific gravity 1.432, and allowed to stand till the two liquids have time to separate, show a black or brown rim at the boundary of oil and acid, while the latter generally has a dirty brown color; but in the case of cotton-seed oil, there is no such black rim, and the acid assumes a pure red tint. If, therefore, a reddish color appears in the acid when olive oil is tested by this method, it shows that cotton-seed oil has been employed as an adulteration.

HARNESS BLACKING.

The *Manufacturer and Builder* (which we generally find thoroughly trustworthy in its recipes) gives the following methods of making harness blacking:—

Mix 4 ounces of hog's lard, 16 ounces of neat's-foot oil, 4 of yellow wax, 20 of ivory black, 16 of brown sugar, and 16 of water. Heat the whole to boiling, and stir it until it becomes cool enough to handle; then roll it into balls about two inches in diameter.

A cheap and good blacking may be made as follows: Soften 2 pounds of glue in one pint of water; dissolve 2 pounds of soap (Castile is best) in one part of warm water; after the glue has become thoroughly soaked, cook it in a glue kettle, and then turn it into a large pot; place the pot over a hot fire and pour in the soap-water, slowly stirring until all is well mixed; then add a half-pound of yellow wax cut in slices. Let the mass boil until the wax is melted, then add half a pint of neat's-foot oil and a sufficient quantity of lamp-black to give it color; let it boil for a few minutes, and it will be fit for use.

For restoring a soiled harness the "French polish" is used. The ingredients are 4½ pounds of stearine, 6¾ pounds of turpentine, and 3 ounces of ivory black. Beat out the stearine to thin sheets with a mallet, mix it with the turpentine, and heat over a water-bath. Stir it continually while heating, and when it is thoroughly heated throw in the coloring matter. Turn the whole into another pot, and stir until it is cool and thick: if not stirred, it will crystallize and the parts will separate. When used it must be warmed, and a small quantity rubbed on the leather with a cloth. Use but little at a time, and put it on very thin. After it has partially dried, rub with a silk cloth, and a polish will be produced equal to that of newly-varnished leather. It may be used also for carriage-tops, straps, etc., and will in no way injure the leather.

To Deodorize Bisulphide of Carbon.—This may be done by keeping the carbonic disulphide (as it would be called in the new nomenclature) for twenty-four hours in contact with powdered corrosive sublimate. The mixture should be continually agitated. It is then to be carefully decanted, and distilled from a little inodorous fat with the aid of a water-bath. Thus purified, the bisulphide has an ethereal odor, and is suitable for the extraction of odorous oils, etc.

Agricultural.

CORN-FODDER FOR MILCH COWS.

We copy the following from the editorial columns of *Hearth and Home* (one of our most able and interesting exchanges), for the purpose of making some comments upon the important subjects brought under discussion:

"We have received an address by Dr. Nichols, delivered last autumn at Greenfield, Mass. Dr. Nichols is the well-known conductor of that excellent monthly, the Boston Journal of Chemistry, who unites to his chemical pursuits very great interest in the practical operation of a farm, now under his management, in the neighborhood of Boston.

"His address is devoted chiefly to water in its agricultural relations. He notes the great percentage of this element in muck and in common barn-yard manure, and the fallacy of estimating their values by weight or bulk.

"As water enters largely into the composition of milk, he advises juicy food for milch cows. In this connection, we are sorry to observe, he declares against maize in drills or sown broadcast for dairy purposes. He even goes so far as to say: 'This is a kind of food for animals not profitable to raise.'

"We are fully persuaded that in this few farmers who have availed themselves of this resource for eking out the parched pastures of September will agree with him.

"We give the doctor the benefit of his explanation of this peculiar doctrine:

'It is not so because the maize-plant is not rich and succulent, but because the conditions under which it is grown are unfavorable to its perfect and healthy development. The natural juices of the plant are richly saccharine at maturity, when grown in hills in open space, with plenty of air and light; but grown in mass, in close contiguity, this principle is almost wholly wanting. To test its comparative value with the green stalks taken from the cornfield, I fed to my herd of cows in August a weighed quantity of the 'corn-fodder,' so called, night and morning, for one week; they were then changed to the field corn-stalks, and the gain in the milk product at the end of the week was a little more than eight per cent, and there was also a manifest improvement in quality. As a rule, all vegetable productions grown under conditions where the chlorophyl, the green coloring principle of plants, cannot be produced in all its richness of tint, are abnormal, immature, worthless. The absence of this principle in the whole of the lower portion of the corn-plant grown in drills, or from broadcast sowing, indicates its watery, half-developed character.'

"And upon this, the doctor goes on to recommend millet, green oats, and clover; but does the doctor propose to sow all these so sparsely as to give free sunshine to the stalks from the bottom up, and so ensure that 'chlorophyllic' development which, he says, is alone compatible with healthful food?

"We can easily believe that the maximum of nutriment in any given plant may be best secured by giving ample space and unchecked flow of sunshine all around it; but that such method is compatible with the economies of practical farming, we are slow to believe; nor can we join Dr. Nichols in counting broadcast or drill-sown corn 'worthless' for food. We have found it to be eaten uniformly with great avidity; and quite as uniformly to ensure a large and full flow of milk."

Remarks.—When we find that our views or opinions upon matters of husbandry do not coincide with those of an observer and farmer, so keen, sensible, and practical as the editor of *Hearth and Home*, the decision is that we must subject them to re-examination to discover the probable error. This matter regarding the value of green-corn fodder, raised in the usual way, as summer feed for milch cows, has provoked much discussion in the agricultural journals, and there is found a decided conflict of views among farmers. It will be observed that our statements are based upon the results of fair and extended experiment, and therefore differ somewhat from opinions which are not thus supported. Mr. Mitchell has, however, found upon actual trial, that "the use of the fodder ensures uniformly a large and full flow of milk." Now, has he ever "weighed and measured" the lacteal products, before and after putting his herd of cows upon it? If he has, the error in results must be sought for in the different conditions under which the plants have been produced. The maize plant, grown in drills in close contiguity, or in mass from broad-cast sowing, is necessarily, almost, or quite, an abnormal growth. Light and air, so essential to healthful plant life, are excluded from a large portion of the stock and leaves; consequently, when cut, they are blanched and watery, like the sprouts which appear upon our tubers and roots when stored in warm cellars. Now, grains and grasses differ in physical structure from the corn plant. Most of them do not rise to a corresponding altitude, and they do not have long, broad leaves to serve as a kind of roof to keep out the sunlight. Moreover, grasses begin to mature much earlier than corn; they have a briefer life. The saccharine and nitrogenous principles begin to flow through the microscopic canals in their structure, before maturity is attained, and hence they contain more nutriment in a green state. The great struggle, the life-work of a plant, is to produce seed to secure the elements of reproduction. A week or two before the seed-forming climax is reached, grasses contain all the rich nutrient principles they are capable of assimilating, and this is the proper time to cut and dry them for food. It is to be further observed that grasses and grains grown in the shade, or where they are crowded together in thick masses, are vastly inferior in quality to those grown under more favorable conditions for access of air and sunlight. The hay, grown on a field that produced three tons to the acre, has not so high a money value as that where but two tons is the product. We grant it may sell at as high price in the market, but every farmer knows it is not worth as much.

If the corn plant is raised under favorable conditions,—not unduly crowded,—and is cut and fed to cows at an early stage in its growth, we do not think even then it will sustain the animals so effectively, and cause so copious a flow of good milk, as any one of a dozen other green crops. At any rate, our careful experiments point to this conclusion. The good husbandry of Mr. Mitchell, at Edgewood, undoubtedly supplies to his animals the corn fodder in its best possible condition, and hence he obtains what, without perhaps giving the matter special attention, he regards as satisfactory results. Notwithstanding all this, we are confident that he cannot contemplate those little patches of pale, sickly "corn fodder" seen upon farms all over New England without disgust. The object of the farmers seems to be to obtain the biggest possible pile of something that "cows will eat," from the most narrow bit of land. This being the object, the end is better reached by sowing corn broadcast, than in any other way. With respect to the nutriment thereby secured, we think it will be quite as well for the farmer to take his thirty cows from the parched pastures in August, and drive them to the nearest brook, as to place before them huge heaps of this watery vegetable production.

BREVITIES.

The Utilization of Sewage.—The advantages, economic and sanitary, of the utilization of sewage are admirably illustrated on a model farm at Madras, where the sewage of Perambore Barracks and an adjacent village is conducted and distributed by an open earthenware conduit over a field reclaimed from an old swamp with stiff clay subsoil. Unfavorable as was the

ground, the yield of grass and vegetables is wonderful, —guinea-grass being produced at the rate of 88 tons of fresh grass, or 29 tons of hay, per acre, and native vegetables thriving luxuriantly. Still more gratifying are the facts that the health of the district has greatly improved, and that the experiment will soon be extended to two other localities near the city.

Sugar Beet Culture. — A French agricultural paper says that the culture of the beet is worth as much to a country as a fertilizer as it is for its product of sugar, the pulp being more valuable than the saccharine material extracted.

Encouraging to the Hens. — The consumption of albumen in certain industries is enormous. In France the calico-printers are the largest consumers, and the demand for their use is steadily on the increase. The print works of Alsace alone consume annually more than 150,000 kilos. of dried albumen, representing rather more than 37,000,000 of eggs, or the production of 250,000 hens; add to this the consumption of the printing works of other parts of France and of other countries, and there is very little doubt th t annually some 150,000,000 eggs are used for that purpose alone.

A NEW INSECTICIDE.

M. Cloez, as the *Revue Horticole* states, has invented a new poison for plant-lice and other small insects. To prepare it, put 3½ ounces of quassia chips and 5 drachms of powdered stavesacre seeds into 7 pints of water, and boil it down to 5 pints. Strain the liquid when cold, and apply it to the plants with a syringe or watering-pot. The preparation has been thoroughly tested in France, and has been found very efficacious.

The *stavesacre* is the *Delphinium staphisagria*, a species of larkspur. The seeds contain *delphinia*, a very poisonous alkaloid. They have sometimes been used to destroy vermin on animals, and also as an anthelmintic.

Water at Sixty Dollars the Ton. — Farmers can hardly afford to pay sixty dollars a ton for common water, and yet we fear they often do pay that exorbitant price for it. Here is the analysis of a popular "*superphosphate*," which is sold largely in all parts of the United States.

Soluble phosphoric acid,	8
Insoluble " "	7
Ammonia,	3
Organic and volatile matter,	30
Bone phosphate of lime,	30
Moisture,	20
Sand and insoluble matter,	2
	100

In this mixture, which is sold at sixty dollars a ton, there is twenty per cent. of *moisture* or water. If the water is removed from one ton of it by the simple process of drying, there will remain but 1600 pounds of the fertilizing material. The loss is therefore one-fifth of the whole amount. Now we do not think it best that all the moisture should be driven off from commercial manures, as in a perfectly dry state they would be inconvenient to use, but it should be taken into account by venders and purchasers. It is certainly a very important item. The moisture in guanos and phosphates varies from 15 to 25 per cent. The quantity should in all cases be known, and the weight deducted when sales are made. Let the price be made upon all fertilizers in a dry condition.

Strawberry Culture. — A very interesting and practical little manual upon strawberry culture has recently been published in this city by J. E. Tilton & Co. It is written by J. M. Merrick, Jr., who has had a large experience in cultivating the delicious fruit. Until we looked over this book we had no idea of the number of varieties of strawberries which have been produced in Europe and in this country. Seventy pages of the book are filled up with a catalogue of these varieties. There is great confusion existing in relation to species in the strawberry family, and notwithstanding so formidable a list of varieties is presented, we doubt if the number of species exceeds a half dozen. The zeal and industry displayed in producing new seedling strawberries, grapes, etc., is certainly wonderful, and perhaps commendable. We doubt, however, if absolutely better varieties than some we now have, will ever be discovered. If we get a very delicate morsel in the shape of a new berry, it is so tender or sensitive it dies even with most careful nursing. Mr. Merrick is quite favorably disposed towards the "President Wilder strawberry," which is a new variety with a long name. We know nothing of this berry, and shall hardly seek its acquaintance, so long as Hovey and a few others drop such satisfactory sweetness into the mouths of those who hang around our tables in June.

A Good Authority on the Value of Corn Fodder. — We are pleased to learn from a communication which appears in a recent issue of the *Republican Statesman*, that the veteran farmer and intelligent experimenter, Levi Bartlett, Esq., of Warner, N. H., fully coincides with us in our views upon green corn fodder. Mr. B. says, that "Dr. N. is unquestionably right in his views respecting the small nutritive value of the usually late and thickly planted corn for fodder." He recommends as substitutes, in addition to those we have named, the cabbage, the rape-plant, and sweet corn grown in hills. Sweet corn is a very valuable plant, and one too much neglected. Mr. Bartlett says, "plant early, and commence feeding as soon as the ears have fairly formed; continue the feed until there is danger of frost; then cut and shock it, and feed to the cows in milk." These are excellent suggestions, and we commend them to the attention of our farmer readers.

Some New Birds. — Through the Peabody Academy of Science, we have received some birds, new in the United States, which it is thought may be domesticated, and become profitable to raise, both as regards meat and eggs. They are natives of Central and South America, and are classed, we believe, by naturalists, as belonging to the pigeon family. They are also related to the ancient Dodos, the celebrated bird which at a comparatively recent period existed in Mauritius. We have two varieties, one called *Palvons*, the other *Paulheils*, and both are very beautiful. In form, they in some respects resemble the turkey, but are not as large. They are nearer in size to the common guinea hen, and the egg they produce is also about the same size. We have not as yet allowed them the "largest liberty" at Lakeside, but with a little "clipping" shall soon venture upon the experiment of "letting them run." It is doubtful if more beautiful domesticated birds exist than Mr. and Mrs. Paulheil. Their plumage, to be sure, just now, is a little shabby, but as an entirely new dress is in course of rapid completion, they will soon be "presentable." If they prove hardy, prolific, and of easy control, they will be a most desirable addition to our list of domesticated birds.

THE FRUITS OF CALIFORNIA.

Dr. Prime, of the N. Y. *Observer*, makes the following observations regarding the fruits of California :—

"But the glory of California is in its pears and grapes. The former grow with a luxuriance and rapidity, and with such abundance of large and luscious looking fruit bending the trees to the earth, that, on entering any of the fruit orchards, a stranger is compelled to break out continually in astonishment. All varieties of pears, if not actually indigenous to the soil, have found in California their true home, and, many of them at least are as delicious as they are finely developed. Some specimens of this fruit, in years past, have been a wonder in the East, where they were sent; but there are a few more left. Pears have become so abundant — even the choicest varieties — that they have actually become a drug in the market; and Bartletts which will weigh a pound, and which blush, when you look at them, like a young maiden, will scarcely pay for sending them to market. I was at a ranch, not an hour's distance from San Francisco, containing all kinds of fruit and pears of every variety, and such fruit as was never seen in any other country, hundreds of bushels, the owner of which informed me that he should leave it all to rot upon the trees, as it would not pay for the picking.

"Grapes grow everywhere in the State with the greatest luxuriance and spontaneously. They require no sort of training; they are trimmed annually almost to the level of the soil, leaving a small stump, and before the season is over. such a burden of the finest of fruit is seen and in clusters like the grapes of Eshcol, as can now scarcely be found anywhere else on earth. The choicest of foreign grapes, which at the East are matured only in graperies by artificial heat, here revel in the open air. I believe all visitors in California, if not the citizens, unite in pronouncing the grapes the finest of its fruit, and they grow in such profusion that all classes may have them at this season as an article of their daily diet. Figs and pomegranates grow with the same luxuriance; the former, as in Oriental countries, producing three crops in a season. The fig-tree grows with astonishing rapidity. I have seen, even among the mountains, and still more in the broad valleys, fig-trees twenty or twenty-five feet in height that could not be more than ten or twelve years old, and covered with the second crop of the largest and finest figs. It is surprising to see so little account made of this fruit, which, in other countries, is an important article of food, and which is more nourishing than any of our native fruits. But the taste for it must be acquired, and it is evident that it has not been extensively acquired in California.

"I have made a more extensive enumeration of the fruits of the State than I intended, although it is only the commencement of a catalogue. Almost anything that will grow in any clime grows here, as if this were its native soil, and in such perfection of form and magnified proportions as can scarcely be approached elsewhere: but with the notable exceptions which I have made, and some, perhaps, which I have omitted, the fruit is not equal in flavor to much of the fruit of our own clime.

Something New in the Cultivation of Corn. — We find the following in the St. Louis *Journal of Agriculture*: "An intelligent and reliable neighbor of ours, who has for many years been making experiments with corn, has discovered an importance and value in replanting corn, which is quite novel and worthy of publication. We have always thought that replanting corn was of little consequence, but this gentleman says it is of so much consequence, he replants whether it is needed or not — or rather, he plants, two or three weeks after the crop is planted, a hill about every fifteenth row each way. If the weather becomes dry during the filling time, the silk and tassel both become dry and dead. In this condition, if it should become seasonable, the silk revives and renews its growth, but the tassel does not recover. Then, for want of pollen, the new silk is unable to fill the office for which it was designed. The pollen from the replanted corn is then ready to supply the silk, and the filling is completed. He says nearly all the abortive ears, so common in all corn crops, are caused by want of pollen, and that he has known ears to double their size in this second filling."

To Make Cows Give Milk. — The agricultural editor of the *Bee-keepers' Journal* vouches for the following, handed him by a friend:—

"If you desire to get a large yield of milk, give your cow, three times a day, water, slightly warm, slightly salted, in which bran has been stirred at the rate of one quart to two gallons of water. You will find that your cow will gain twenty-five per cent. immediately under the effects of it, and she will become so attached to the diet as to refuse to drink clear water, unless very thirsty, but this mess she will drink almost at any time, and ask for more. The amount of this drink is an ordinary water-pailful at each time, morning, noon, and night. Your animal will then do her best at discounting the lacteal."

Boston Journal of Chemistry.
BOSTON, JUNE 1, 1870.

PROSPECTUS.

VOLUME V. of the JOURNAL, commencing July 1, 1870, will be increased in size, each number containing not less than *twelve pages* of reading matter. It will be printed from stereotype plates, on the finest book-paper; and we shall continue to make it the *best and cheapest scientific journal in the world.* *The terms for the* JOURNAL *will be one dollar per year; single numbers, ten cents.*

The JOURNAL will be, as it has been, independent, unbiased, careful, and reliable. No individual, corporation, or organization is rich or influential enough to suppress its opinions, or in any way control its influence. It will continue to expose frauds, schemes, and speculations, which profess to originate in or grow out of progress in science and art. The great and growing evil of *adulterations* in articles of food, medicine, fertilizers, and substances used in the arts, will receive special attention, and the nature of the sophistications and adulterations will be fully exposed. We shall present numerous useful practical formulæ, recipes, and scientific suggestions, which alone will be worth many times the price of the publication.

TO PHYSICIANS,

It will continue to be of *special service*, as it will keep them informed of the nature of all new remedial agents, all new discoveries in chemical and medical science, all new principles or processes connected with toxicology and pharmacy.

TO DRUGGISTS,

It will come as a reliable friend and adviser, affording information and instruction upon all matters relating to the manufacture and dispensing of medicines, and the other substances and agents produced or vended by them.

TO FARMERS,

It will impart information upon the important subjects of the chemistry of plant-growths, and the nature and preparation of fertilizing agents.

TO CHEMISTS, MANUFACTURERS, ARTISTS, TEACHERS, STUDENTS, CLERGYMEN,

All intelligent readers, men and women, everywhere, the *Boston Journal of Chemistry* will supply information and instruction of the highest importance and value.

The JOURNAL has, at the present time, a large army of friends, and these we ask to aid us in extending its circulation. Our patrons know how instructive and useful it *has been* in the past: we assure them it will be even *better* in the future. Cannot each one send us a new subscriber, to commence with Vol. V.?

We make this offer to *new subscribers*: All those who subscribe, and send us *one dollar* in advance, will receive the remaining numbers of Vol. IV. They will receive the whole of Vol. V., and all the numbers of Vol. IV. which are issued, after January 1, 1870. *Subscribe early*, and thus obtain one-half of Vol. IV. as a gratuity.

PREMIUMS.

To any person who will send us the name of one new subscriber, with $1.00, we will send a fine mezzotint *carte de visite* photograph of the late George Peabody. For two new subscribers, with $2.00, a *cabinet* size photograph of the late George Peabody. For three, with $3.00, one copy of the JOURNAL free for one year, or a Petite Microscope. For five, with $5.00, a set of twenty carpenter's tools in a hollow handle. For six, with $6.00, one copy of Dr. Nichols' Chemistry of the Farm and the Sea; Rolfe and Gillet's Hand-book of the Stars, Hand-book of Chemistry, or Chemistry and Electricity; or the Nursery Magazine. For ten, with $10.00, one copy of Dr. Lord's Ancient States and Empires; or Oliver Optic's Magazine; Our Young Folks; or, The Riverside Magazine. For twelve, with $12.00, Tilton's Horticultural Magazine. For sixteen, with $16.00, one copy for one year of either of the four dollar Magazines mentioned in the list following; or a * Boy's Tool Chest, thirteen inches long, eight inches wide, and eight inches high, with a complete set of Carpenters' tools, saw, plane, etc. For twenty, with $20.00, the N. Y. Journal of Psychology, or the Philadelphia Medical and Surgical Reporter. For twenty-five, with $25.00, a fine * Set of Croquet implements. For eighty, with $80.00, a * Complete set of Chemical Apparatus, suitable for all the experiments described in Rolfe and Gillet's Handbook of Chemistry. For one hundred, with $100.00, one * Cutter Clinical Microscope; or, a fine * Waltham Watch, in a silver case.

In all the cases mentioned above, we give to each new subscriber the JOURNAL from January, 1870, to July, 1871, or *eighteen* papers for the price of *one year's subscription*. This is exclusive of the premium to the getter-up of the Club.

☞ Premiums are allowed only upon *new* subscribers, not on renewal of subscription by old subscribers.

* The express charges upon these articles to be paid by the receiver.

J. R. NICHOLS & CO., Publishers,
BOSTON.

THE JOURNAL GIVEN AWAY.

ON receipt of the publisher's price of any one of the following periodicals, we will send *both the* JOURNAL *and that periodical* for one year. This offer applies to those persons only who are not already subscribers to either.

ECLECTIC	$5.00
EVERY SATURDAY	5.00
NATION	5.00
N. Y. JOURNAL OF PSYCHOLOGY	5.00
PHILA. MEDICAL AND SURGICAL REPORTER	5.00
PUTNAM'S MAGAZINE	5.00
AMERICAN NATURALIST	4.00
APPLETON'S JOURNAL	4.00
ATLANTIC	4.00
COLLEGE COURANT (*New Haven*)	4.00
GALAXY	4.00
HARPER'S MONTHLY, WEEKLY, *or* BAZAR (*each*)	4.00
LIPPINCOTT'S MAGAZINE	4.00
N. Y. MEDICAL JOURNAL	4.00
OLD AND NEW	4.00

GOOD WORDS FOR THE YOUNG	2.50
OUR YOUNG FOLKS	2.50
OLIVER OPTIC'S MAGAZINE	2.50

END OF VOLUME FOURTH.

THE present issue ends the 4th Volume of the Boston JOURNAL OF CHEMISTRY. The paper was commenced in July, 1866, as an experiment, and without any expectation, on the part of its editor or publishers, of establishing a popular journal of science upon a permanent basis. But its success has been complete, and we do not hesitate to say that we believe, upon its fourth anniversary, it *has a larger circulation than any journal of its class published in Europe or in the United States.* It has, thus far, been continued under many disadvantages, which it is hoped will in a measure be overcome in the future. During the past four years, the editor, while pressed with business cares, and many exacting duties, has carried it through, almost unaided and alone. If we had not been cheered by constant words of kindness and encouragement, and by a patronage which may in all fairness be regarded as unparalleled in the history of journalism, the paper would long since have passed into other hands. Since our patrons have done so much for us, we are determined to do all we can for them. The new volume will commence under favorable auspices. Able assistance has been secured in each department, and improvements will be introduced, which we hope will prove acceptable to our readers. The JOURNAL is to be considerably enlarged, and the price will be one dollar per annum.

"PEN PALSY."

A CORRESPONDENT sends us the following extract from "Good Health," and asks our opinion on the subject:—

"We have had recently several cases of paralysis of the hand and arm, from the elbow, which have evidently been induced by the use of steel pens. One young lady who had been engaged in copying for some years, became unable to use the right hand. . . . . While Rev. Dr. Walker was President of Harvard College, he had a lame arm brought on by using steel pens."

The late President Felton, of Harvard College, stated in a public lecture that several of his acquaintances had been permanently injured by the use of steel pens. At that time, quite a number of similar cases were reported in the papers, and "Bill's anti-nervous penholder" became popular in certain quarters as a prophylactic device. This penholder differs from the ordinary kind in being made entirely of wood, so that there is no metallic "conductor" between the steel pen and the fingers. We confess that we have never seen any satisfactory evidence that the steel pen is responsible for the so-called "palsy." The thing seems very improbable, from a scientific point of view, if not impossible. We like the wooden penholders, but we have thought that the relief which the pen-paralytics have found in using them is due to the fact that, being of greater diameter than the common kind, they cramp the fingers less, while at the same time they are easier to hold, especially when the fingers perspire.

A MODEL SCHOOL FOR YOUNG LADIES.—We regard Bradford Academy, as now conducted, with its new and magnificent school building, a model of excellence in everything relating to the education of young ladies. The new structure is so complete, convenient, and elegant, that all friends of education who desire to learn regarding the nature of modern improvements in school buildings, should visit and inspect its arrangements. This building was formally dedicated May 11, when the chairman of the building committee, Dr. George Cogswell, of Bradford, delivered it into the hands of the Board of Trustees, every part having been completed. The exercises were exceedingly interesting. The cost of the structure, furniture and apparatus is about $150,000, which has been raised by private subscription. The situation of the Academy is delightful, commanding as it does a full view of the valley of the Merrimac for many miles, and also the city of Haverhill upon the opposite bank of the river. Parents who have daughters to educate, and who desire to place them where everything will be done for their health and happiness, and for their mental and moral training, should send them to Bradford Academy.

EDITORIAL NOTES.

CALIFORNIA DIAMONDS.—Diamonds have been found in several localities in California, but as yet they have been of small size and value. One, found at Cherokee Flat, was valued at fifty dollars in the rough, but that was an exceptional instance. Some maintain that diamonds may be looked for wherever gold abounds, and that the only reason why they have not been obtained more frequently in California is because the miners have not known enough to detect them. When first dug up the precious gem is covered with an opaque crust, which hides its brilliancy and its crystalline form. Such pebbles might lie in every field without being recognized. This matter is beginning to attract considerable attention in California, and if diamonds are really abundant in that region, they will not long escape the Yankee eye.

NEWSPAPER SCIENCE.—Our readers will recollect that we have several times had occasion to notice the startling statements on scientific subjects which we find in the papers of the day. A reverend writer, who, like the Bishop of Western New York, writes D. D. after his name, has been enlightening the patrons of a Presbyterian journal out West on the developments of modern science. Among the *dicta* he lays down we notice the following: "No simple substance exists in nature." It has been generally accepted as a fact that many of the chemical elements—which are "simple substances," so far as our present knowledge goes—are found uncombined in nature; but since, according to our philosophic divine, "true science is founded on *faith*" (not, of course, on *sight*), we must assume that chemists

have erred in trusting the evidence of their eyes on this point.

Again, this reverend gentleman tells us that recent geologists have demonstrated that "granite never was a metal," etc. He intimates that the contrary view has been an accepted "geological dogma," but we have never happened to meet with it. The worthy Doctor is right, however, in rejecting it. The non-metallic character of granite may be considered as settled beyond a doubt. We have the impression that the honor of this discovery belongs to the eminent chemist who, as we stated in our last number, has proved that the electric light is "essentially different" from the calcium light. With what new thing in science he will *next* astonish the world, we will not presume to predict.

The *Panama Mail* quotes the following from *El Siglo*, a Mexican journal, of March 2d, 1870: —

"The Panama Railroad Company has found itself compelled to double the force of its telegraphic batteries, on account of it being the custom of the monkeys — so numerous in that part of the world — to congregate and practise gymnastic exercise upon the telegraph wires. It is believed that the shock will be so strong that there will not be an acrobat in those woods able to resist its effects."

We regret that the writer does not inform us what kind of batteries are used on that line. They must be very different from anything employed for telegraphic purposes in this part of the world, if, when "doubled," or multiplied to any extent, they can send a current over the wires which a monkey of acrobatic proclivities cannot withstand. Or, are the quadrumanous gymnasts of the Isthmus peculiarly sensitive to the "shocking" effects of current electricity administered in that way?

A New Use for Jute. — Not long ago, at Liverpool, a hundred bales of jute were purchased for shipment to America, for the purpose of being dyed and sold as "ladies' back hair." It is said that it was not a single instance of the kind. If we may believe what we are told concerning the quality and condition of some of the foreign *hair* imported for a similar purpose, the substitution of jute would be preferable as "a choice of evils."

This vile fashion of wearing false hair was introduced into England only about three centuries ago; in 1572, according to the old chronicler Stow. Shakespeare appeared to have had a great antipathy to the practice. In the *Merchant of Venice* (iii. 2) Bassanio includes it among the shams that deceive the world: —

"So are those crisped snaky golden locks,
Which make such wanton gambols with the wind
Upon supposed fairness, often known
To be the dowry of a second head;
The skull that bred them, in the sepulchre."

In *Love's Labor Lost* (iv. 3), Byron says: —

"O, if in black my lady's brows be deck'd,
It mourns that painting, and usurping hair,
Should ravish doters with a false aspect."

See also *Timon of Athens* (iv. 3): —

"Thatch your poor thin roofs
With burdens of the dead."

In the sixty-eighth Sonnet he refers to the good old times,

"Before the golden tresses of the dead,
The right of sepulchres, were shorn away,
To live a second life on second head, —
Ere beauty's dead fleece made another gay," etc.

Decidedly Cool. — Herr Rudorff has been making experiments upon the refrigerating powers of certain salts, and the most remarkable appear to be the sulpho-cyanides of ammonium and potassium. Of the former 133 parts added to 100 parts of water reduced the temperature from 12° C. (53.6° F.) to —18° (almost exactly *zero* F.); and of the latter 150 parts added to 100 of water sent the mercury down from 11° C. (51.8° F.) to — 24° C. (—11.2° F.) The salts should be in a fine powder, and be stirred into the water by a glass rod, and the water should be contained in a thin glass vessel surrounded by loose cotton.

The State Board of Health. — The London *Lancet* speaks with much admiration of the Massachusetts Board of Health, quotes at length from the opening address of its chairman, remarks the comprehensive views of American Legislatures as shown in the founding of such a board, and commends several of the features and plans of the organization to the imitation of English sanitarians. The *Advertiser* hopes that the proposition to extinguish this Board after six months' work will never be heard of in London. Fortunately for the honor and the welfare of the State, this backward step was not taken.

Counterfeit Worcestershire Sauce. — Three men have been arrested in Philadelphia for making a counterfeit of this English sauce. The sales of the genuine article in this country amount yearly to about a quarter of a million of dollars, but it is said that those of the counterfeit greatly exceed that amount.

Coffee and Civilization. — It has been said that the relative civilization of a country may be measured by the amount of coffee which it consumes. That is going rather far, perhaps, but there can be no doubt that there is some ground for the opinion. A New Orleans journal finds a confirmation of this in the fact that the negroes of the South have come to use a good deal more coffee since emancipation compelled them to *think* as well as work.

The Air as Affected by Cities, etc. — In an official report Dr. Angus Smith, who is Inspector under the British Alkali Act, gives much interesting information as to the effect of large cities, and especially of manufactories, in contaminating the atmosphere. His principal conclusions are as follows: —

"The rain from the sea contains chiefly common salt, which crystallizes clearly.

"The sulphates increase inland before large towns are reached.

"The sulphates rise very high in large towns, because of the amount of sulphur in the coal used, as well as decomposition.

"When the air has so much acid that two or three grains are found in a gallon of the rain water, or forty parts in a million, there is no hope for vegetation in a climate such as we have in the northern parts of the country.

"Free acids are not found with certainty where combustion or manufactures are not the cause.

"In Manchester, in 1867, the maximum acidity of the rain was 7.39 grains per gallon, and the minimum 0.31 per gallon."

Cologne Cathedral. — *Every Saturday* (which grows better and better with every number) gives an admirable double-page picture of Cologne Cathedral, as that "perfect flower of Gothic architecture" will be when completed. It is *not* already completed, as the paper intimates; so that Satan — who, according to the old legend, vowed that it should never be finished — is not baffled yet. In 1848, when, on the six-hundredth anniversary of the beginning of the work, the nave of the church was dedicated, many English and American papers stated that the edifice was complete. But the two lofty spires had not then risen above the roof, and, though the work has been going on steadily ever since, they are still some two hundred feet short of their intended height, which is five hundred feet or more.

The First Printing in America. — Every year or two the following statement goes the rounds of the papers: "The first printing in America was done at Cambridge, Mass., in 1639." It has just now started on its travels, and appears likely to make the usual circuit of the literary world without being challenged. As it is not true, we feel bound to show it up. The first book printed in *America* was done at Mexico, in the year 1544, and was entitled *Doctrina Christiana para los Indios.* The first printing in *British* America was at Cambridge, in 1639, when an almanac and the *Freemans Oath* were issued. The first *book* published in the Colonies was printed the next year (1640), and is known as "The Bay Psalm Book." It was a metrical version of the Psalms, prepared "for the use, edification and comfort of the saints, in public and in private, especially in New England."

Poetry had been written, though not printed, in New England at even an earlier date. The Reverend William Morrell, who came to Plymouth in 1623, and returned to London the next year, wrote a poetical description of the new country *in Latin.* The first verses in English by a colonist were probably written about 1630. The author's name has been lost. They begin thus: —

"*New England's annoyances, you that would know them,*
Pray ponder these verses, which briefly do show them.
The place where we live is a wilderness wood,
Where grass is much wanting that's fruitful and good:
Our mountains and hills and our valleys below
Being commonly covered with ice and with snow:
And when the northwest wind with violence blows,
Then every man pulls his cap over his nose:
But if any's so hardy and will it withstand,
He forfeits a finger, a foot, or a hand.
. . . .
Instead of pottage and puddings, and custards and pies,
Our pumpkins and parsnips are common supplies;
We have pumpkins at morning, and pumpkins at noon;
If it was not for pumpkins, we should be undone."

We do not know that antiquarians have traced the phrase, "some pumpkins!" so far back as these old colonial times, but it is evident that it would have been peculiarly significant in a day when the fate of the Commonwealth depended upon that homely vegetable, if we may believe this bucolic minstrel.

Oxygen and Combustion. — A newspaper writer says: "Strange as it may appear, considering its universal connection with combustion, — as that phenomenon is known outside of the laboratory, — oxygen, of all created elements, is the only one that will not burn!"

Since ordinary combustion consists in the union of the burning substance with oxygen, the latter really burns as well as the former. We commonly speak of the oxygen as a *supporter of combustion* and of the other body as a *combustible*, but the distinction, though convenient, is a wholly arbitrary one. A jet of oxygen may be made to burn in an atmosphere of coal-gas, just as a jet of coal gas burns in oxygen or in the air. In either case, the burning takes place where the two come together, both are burned, and of course both are supporters of the combustion. But even if we take the above statement as the writer meant it, there are "created elements" (nitrogen, for instance) which will no more burn than oxygen will.

Protection of Lead Water Pipes. — A paragraph is going the rounds of the scientific journals and the newspapers generally, to the effect that Dr. Schwarz, of Breslau, has found a simple way of protecting lead pipes from the action of water, by forming on their inner surface an insoluble sulphide of lead. This is done by filling the pipes with a warm and concentrated solution of sulphide of potassium or of sodium, which is left in contact with the lead for about fifteen minutes. This may be a new thing in Breslau, but more than two years ago we suggested in the Journal a similar process as, on the whole, the best that we knew for the purpose. The directions we gave were as follows: dissolve one pound of sulphide of potassium in two gallons of water, and let it remain in the pipe twelve hours, or until the inside is thoroughly blackened. The same recipe was given in Rolfe and Gillet's "Handbook of Chemistry," published in 1868. The use of a warm saturated solution, as Dr. Schwarz directs, would do the work in shorter time, which might be more convenient in some cases.

LITERARY NOTES.

W. J. Holland, of Springfield, Mass., has published *Personal Beauty, how to preserve it in accordance with the laws of health, by D. G. Brinton, M. D., and Geo. H. Napheys, M. D.* If every young lady and gentleman in the United States who desires to be *beautiful* should buy this book, the publisher and authors would receive a generous compensation for their labors. We have examined the work quite carefully, and are free to say that it is a very interesting and useful treatise. It is written, or compiled, by two cultivated and distinguished physicians of Philadelphia, and whatever they are willing to associate their names with, must be reliable and worthy of attention. The work treats upon matters connected with sanitary rules, medicines, cosmetics, the symmetry of the human figure, the literature of beauty, etc., and is quite exhaustive upon these topics.

Henry C. Lea, of Philadelphia, sends us *Tanner's Manual of Clinical Medicine, revised and enlarged by Dr. Tilbury Fox.* It is a *handy book* for the practitioner, and contains in a small space a large number of facts and suggestions of the highest usefulness. All modern discoveries and improvements in medicine and surgery are treated of in its pages.

Messrs. Charles Scribner & Co., of New York, have recently published a work upon *American Political Economy* by *Prof. Francis Bowen*, of Cambridge. The judgment we may form of a work of this nature is hardly worthy of consideration, as it treats of a department of study and research considerably removed from that which we have been led to investigate; but there is evidence in the book that much thought and study have been bestowed upon it. It will undoubtedly be of interest and value to the political economist.

The same publishers have issued two more volumes of their "Library of Wonders," which we have so often commended, — *Wonders of Italian Art* and *Wonders of the Human Body*. The latter is a popular manual of physiology, well written and well illustrated. Two more volumes of the very neat and cheap edition of Froude's *History of England* are now ready.

Hours at Home promises, for its June number, a paper on "Sun Spots," by the lady astronomer, Miss Maria Mitchell.

The Rural Carolinian is an excellent monthly magazine, published by Messrs. Walker, Evans, & Cogswell, at Charleston, S. C., for two dollars a year. It well deserves the success it appears to be winning.

The American Supplement of the reprint of the *Chemical News*, published by W. A Townsend & Adams, New York, is to be doubled in size. This supplement, edited by Prof. C. F. Chandler, adds not a little to the interest and value of the journal.

The Five-cent Metric Standard. — We are informed that the five-cent coin, which our Uncle Samuel has issued as a popular standard of the metric system, is by no means of uniform weight. A correspondent, who has weighed a good many of them, finds that different specimens vary as much as three grains. In one instance thirty-nine heavy ones balanced forty light ones. "Undoubtedly," as he remarks, "the intention was to make the new coinage a key to the metric system of weights and measures, but it is evident that accuracy has not been obtained."

The apparent variation in the *diameter* of the coin we have explained in a former number of the Journal.

Medicine.

ON THE SLEEP PRODUCED BY CHLORAL.

We have not seen any observations regarding the *nature* of the sleep resulting from the use of the hydrate of chloral, yet it is a point of much interest, and worthy of study. In the numerous experiments made with the agent in our own case, and from experiments made upon others, we are led to think that the sleep is peculiar, certainly unlike natural sleep in its general influence upon the system. It is doubtful if the recuperative action upon the brain in a large degree corresponds with it. The curtain of the mind seems to be fully drawn; there is no dreamy condition, nothing akin to somnolentia, in the sleep produced by chloral. The insensibility, although apparently entire, is less profound than in healthful, natural sleep. A slight noise awakens the patient, and the wakefulness is perfect, although it may not last but for a moment. At one time, having taken 30 grains of the agent, and fallen asleep, a loose blind moved by the wind thumped against the house. The awakening was instantaneous and complete; no lingering drowsiness was felt, and yet in perhaps half a minute insensibility was resumed. The sleep has no interval, or season of insupportable drowsiness; there is no swaying to and fro, between the conscious and unconscious condition; sleep comes like the sudden darkness when a bright light is extinguished in a room in the night-time. If sleep is simply the suspension of the operation of the senses, if it is nothing but unconsciousness, then we have no difficulty in defining the exact influence of chloral; but we incline to the opinion that in natural sleep there is a peculiar physical or mental condition existing independent of the insensibility. The morning after a night of sleep induced by chloral, there is no headache, no nausea, no unpleasant feelings whatever, but an indefinable sense of lightness, an exhilaration, which is not like that produced by stimulants. The impression is that there has been a pleasant state of unconsciousness without or with imperfect sleep. The body and the mind are *refreshed*, but not, in kind or degree, like that which results from natural, healthful slumber. It may be that chloral does not positively produce sleep, but a prolonged, peculiar anæsthesia, which serves many of the purposes of sleep. Manifestly, we know at present but little regarding the precise nature of the effects produced upon the functions of the mind and body by this drug. We know enough, however, to feel convinced that it is a most important addition to materia medica, and that it is better calculated to relieve a large class of suffering patients than any agent hitherto suggested.

PHYSIC IN FRANCE.

We glean a few items from the recent French correspondence in English journals.

Chloral is still in great favor with the Paris doctors. The amount used is considerable, as doses varying from half a gramme (7.7 grains) up to three and four grammes are given. In one case, three doses of four grammes each were given during one night; but the patient hasn't woke up yet.

Among novelties in trade, we note artificial manna, clean, white, and not easily distinguishable from the natural product; and artificial linseed-meal or marshmallow poultices, which promise to have a large sale.

The Frenchman wants but little physic here below, but wants that little nice. Hence the utmost skill of the pharmacist is exerted to make medicine palatable, if not positively delicious; and the result is all sorts of syrups, wines, elixirs, granules, and purgative lemonade, as refreshing as one would get at a *café* on the Boulevards. A delicately flavored draught often proves very profitable to the maker, for, like a good brand of wine, it soon becomes famous with epicurean invalids. Americans, who, like Britons, are much addicted to medicine, even in the nauseous forms in which it is furnished them at home, indulge in it extravagantly when they find it "not bad to take," and are therefore the best customers of the Parisian *pharmaciens.*

The *shops* of the apothecaries in France are very much inferior to those in England, and to ours. With a very few exceptions in Paris, they are small, meanly furnished, and dirty.

St. Claire Deville and some other scientific men have been trying experiments upon the degree of atmospheric pressure that a man can endure. They lately invited a company of friends to take breakfast with them in a boiler, under a pressure of three atmospheres, but were glad to open the safety valve before the meal was finished.

THE ORIGIN OF BLOOD-LETTING.

According to Pliny, the practice of blood-letting had its origin in Egypt. He tells us that the hippopotamus, when it becomes too fat and unwieldy, bleeds itself by pressing a vein of the thigh against a pointed reed; and that physicians took the hint of the operation from the corpulent pachyderm. The story has been laughed at as a mere fable without even the semblance of a foundation; but modern naturalists have observed on the skin of the hippopotamus a red exudation, which might easily be taken for blood. This fact may be considered as a confirmation, or, at least, as an explanation of the Egyptian story. As Dr. Lankester has suggested, either the Egyptian priests saw this red exudation, and imitated it with the practice of bleeding, or the Egyptian laity noticed the blood-colored sweat, and connected it with the practice of bleeding then in vogue, because they "could not understand that their wise men could discover a remedy untaught."

The red sweat of the river-horse is *not* blood, but merely perspiration colored by a pigment secreted in the skin. It has been examined with the spectroscope, and does not give a blood spectrum; and with the microscope, which shows no blood corpuscles, while it does show other corpuscles with pigmentary granules.

CHIT CHAT.

HERE is a quaint anecdote from the biography of Dr. Marshall Hall. Dr. Wilkins had lent Dr. Hall the well-known book, "Body and Soul," and as it was not returned in due time, he sent this note: "Dear Doctor, do send back my body and soul; I cannot exist longer without them." The servant who received the note read it (as servants sometimes will), and horror-stricken rushed into the kitchen, crying, "Cook, I can't live any longer with the Doctor!"—"Why, what's the matter?" "Matter enough," replied the man; "our master has got Dr. Wilkins's *body and soul*, and I don't dare to stay where there are such goings-on!"

What Dr. Hall says of *strychnia* is not bad: "Its least action is that of an invaluable spinal tonic; its mean action is that of an invaluable spinal stimulus, terrific in its effects; its most violent action is that of the thunderbolt!"

As good an instance of "sharp practice" as we have ever heard of, was that of David Phillips, in Ohio, who was acquitted of the murder of a man, on a plea of insanity. He had secured his lawyers by giving them a mortgage on his farm, but now repudiates the mortgage, on the ground that he *was insane when he made it*, according to the showing of these same lawyers!

The difference between rheumatism and gout was forcibly, if not scientifically, stated by the Frenchman who said: "Place the joint in a vise and screw it up until you can endure it no longer; that is rheumatism. Then give the instrument another twist; that is gout." And yet an English writer gives it as a fact, that some people are anxious to have the gout, because they think it fashionable!

A correspondent of the *Michigan University Medical Journal* suggests that hydrate of chloral was the drug which the friar administered to Juliet. Note what Shakespeare makes him say of it:—

"Take thou this phial, being then in bed,
And this distilled liquor drink thou off;
When presently through all thy veins shall run
A cold and drowsy humor, which shall seize
Each vital spirit.
And in this borrowed likeness of shrunk death
Thou shalt remain *full two and forty hours,*
And then awake as from a pleasant sleep!"

ALCOHOL AND ANIMAL HEAT.

PROF. BING, of Bonn, has been investigating the influence of alcohol upon animal heat, and the conclusions at which he has arrived are as follows:—

"That the heat of the body is always lowered by alcohol, and that alcohol preserves life in febrile affections, where the temperature rises very high, by its antipyretic properties.

"That extreme depression of the vital powers in febrile cases is most frequently dependent upon the temperature of the blood, and passes off when it falls.

"That the number and strength of the contractions of the heart always rise under the use of alcohol. Whenever, therefore, such an effect would be injurious, alcohol would be an improper remedy.

"That in all probability alcohol lowers the temperature, by the retarding influence which it exerts over the oxidizing process."

WRITING PRESCRIPTIONS.

DR. MONOD, in the *Bulletin de Thérapeutique*, urges physicians to use no abbreviations or figures in writing prescriptions, but to write everything out in full. Instead of

Tinct. op. deod., f℥iss,

he would have

Deodorized tincture of opium, one-and-a-half fluid drachms.

He adds: "I am certainly not the first to express the wish that prescriptions be written so as to avoid errors; God grant that I be the last." To which if there were any hope of it, we would say, Amen!—*Phila. Med. and Surg. Rep.*

MEDICAL LATIN.

THE constant use of the dog-Latin of prescriptions appears to make some of our medical brethren oblivious of the purer Roman tongue as they learned it in their student days. We have seen in several instances *per oram* for *per os*, and the leading article in a Western medical magazine, for April, has for its motto "*Cano Arma et Viri*,"—a perversion of the familiar *Arma virumque cano*, which is worse in its way than Punch's recent translation of the same, "Our arms and strength are in the cane."

AN EXPLOSION.—A druggist in Massachusetts writes, that in attempting to rub up in a wedgwood mortar a mixture of four parts of chlorate of potassa and one of tannin, he got an explosion which blistered his hands, and did considerable other damage. It is quite probable that in the mortar, or in one or both of the ingredients, sulphur was present, which forms with chlorate of potassa a detonating compound dangerous to prepare. The two articles named would not, when mixed, spontaneously explode.

MEDICAL PROPERTIES OF EGGS.—The white of an egg has proved of late the most efficacious remedy for burns. Seven or eight successive applications of this substance soothe pain and effectually exclude the burn from the air. This simple remedy seems preferable to collodion, or even cotton. Extraordinary stories are told of the healing properties of a new oil which is easily made from the yolk of hens' eggs. The eggs are first boiled hard, and the yolks are then removed, crushed, and placed over a fire, where they are carefully stirred until the whole substance is just on the point of catching fire, when the oil separates and may be poured off. One yolk will yield nearly two teaspoonfuls of oil. It is in general use among colonists of South Russia as a means of curing cuts, bruises, and scratches.

NEW AND VALUABLE

Text-Books in Physics

By

W. J. ROLFE,

FORMERLY HEAD MASTER OF THE HIGH SCHOOL, CAMBRIDGE, MASS.,

And

J. A. GILLET,

PROFESSOR OF MATHEMATICS AND PHYSICS IN THE FEMALE NORMAL AND HIGH SCHOOL OF THE CITY OF NEW YORK.

THE CAMBRIDGE COURSE IN PHYSICS,

IN THREE VOLUMES:

I. CHEMISTRY, $2.00.
II. NATURAL PHILOSOPHY, $2.00.
III. ASTRONOMY, $2.00.

☞ The new revised editions of these books have been brought down to the beginning of 1870, and they give a more accurate and complete view of the present state of the sciences than any other elementary books published in this country. Physicians and others who wish concise accounts of "Modern Chemistry," of the new theories and investigations in Sound, Light, Heat, Electricity and Meteorology, of the latest discoveries in Solar Physics and other departments of Astronomy, of the Conservation of Energy, etc., should get these books.

THE HANDBOOK SERIES,

IN THREE VOLUMES:

I. HANDBOOK OF CHEMISTRY, $1.00.
II. HANDBOOK OF NATURAL PHILOSOPHY, $1.00.
III. HANDBOOK OF THE STARS, $1.30.

These are not abridgments of the larger works, but are wholly new and independent books, differing from the others in the selection, arrangement and treatment of topics, so far as was necessary to fit them for a briefer and easier course of study. They are simple in style, and eminently practical, yet thoroughly scientific, and giving the results of the latest discovery and research.

☞ Any of the above books sent by mail postpaid, on receipt of advertised price. Circulars with fuller description, testimonials, etc., mailed on application.

WOOLWORTH, AINSWORTH & CO.

PUBLISHERS,

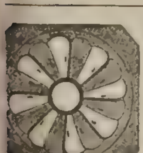
51 John St., New York.

CLEVELAND HOMŒOPATHIC

Hospital College.

For further information address

H. F. BIGGAR, M. D.,
REGISTRAR,
Park Place, Cleveland, O.



GARRAT'S ELECTRIC DISK.

For local rheumatism, weakness, pain or palsy. It is simply to be worn on the body or limb (as if a plaster) for constant localized electricity. While it is active it is easy and perfectly safe in every case. For sale everywhere by first class Druggists.

BOERICKE & TAFEL,

Homœopathic Pharmaceutists and Publishers,

145 Grand St., between Broadway and Elm St.,

Have constantly on hand a full assortment of Homœopathic Medicines and books for Physicians and family use. Medicines sold by whole sets or single vials.

Orders by mail promptly attended to.

CODMAN & SHURTLEFF'S

APPARATUSES FOR

Atomization of Liquids for Inhalation, Local Anæsthesia, &c.

By the Atomizer any medicated liquid may be converted into the finest spray. In this state it may be inhaled into the smallest air-cells, thus opening a new era in the treatment of all diseases of the throat and lungs.

The Complete Steam Atomizer for Inhalation, &c.

(See Fig. 15.)

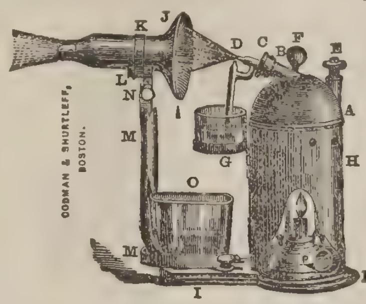


Fig. 15. The Complete Steam Atomizer. For Inhalation, &c.
Pat. Mar. 24, 1868, and Mar. 16, 1869.

It consists of the sphere-shaped brass boiler A, steam outlet tube B, with packing box C, formed to receive rubber packing through which the atomizing tube D passes, steam tight, and by means of which tubes of various sizes may be tightly held against any force of steam, by screwing down its cover while the packing is warm; the safety valve E, capable of graduation for high or low pressure by the spring and screw in its top, the non-conducting handle F, by which the boiler may be lifted while hot, the medicament cup and cup-holder G, the support H, iron base I I, the glass face-shield J, with oval mouth-piece connected by the elastic band K with the cradle L, whose slotted staff passes into a slot in the shield-stand M M, where it may be fixed at any height or angle required by the milled screw N.

The waste-cup, medicament-cup, and lamp are held in their places in such a manner that they cannot fall out when the apparatus is carried or used over a bed or otherwise.

All its joints are hard soldered.

It cannot be injured by exhaustion of water, or any attainable pressure of steam.

It does not throw spirts of hot water, to frighten or scald the patient.

Is compact and portable, occupies space of one-sixth cubic foot only, can be carried from place to place without removing the atomizing tubes or the water, can be unpacked and repacked without loss of time.

Will render the best of service for many years, and is cheap in the best sense of the word.

Price, $6. Neatly made, strong, Black Walnut Box, with convenient handle, additional $2.50.

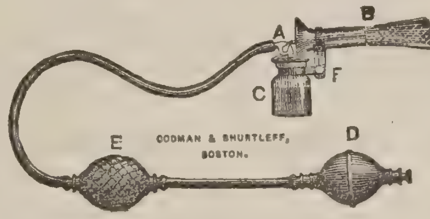

Fig. 5. Shurtleff's Atomizing Apparatus. (Patented March 24, 1868.)

Shurtleff's Atomizing Apparatus, (See Fig. 5,)

For Inhalation, and, with suitable tubes, for Local Anæsthesia, and for making direct local applications of atomized Liquids for a great variety of purposes. [See our Pamphlet.]

The most desirable Hand Apparatus.

Rubber warranted of *very best quality*.

Valves of hard rubber, every one carefully fitted to its seat, and work perfectly in all positions.

The Bulbs are adapted to all the Tubes made by us for Local Anæsthesia in Surgical Operations, Teeth Extraction, and for Inhalation. Price $4.50.

Each of the above Apparatuses is supplied with two carefully made annealed glass Atomizing Tubes, and accompanied with directions for use. Every Steam Apparatus is tested with steam, at very high pressure. Each Apparatus is carefully packed for transportation, and warranted perfect. Also,

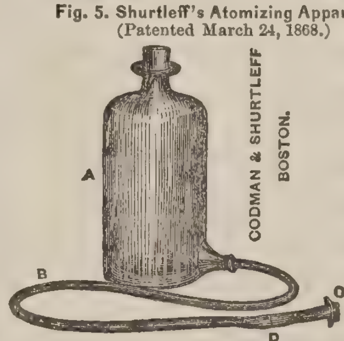

Fig. 6.—Nasal Douche. With Two Nozzles,—$2.00.

THE BOSTON ATOMIZER, with two glass atomizing tubes	$3.00
THE TREMONT ATOMIZER, with two glass atomizing tubes	2.50
NICKEL PLATED TUBES, for Local Anæsthesia and for Inhalation, each	2.00
RHIGOLENE, for Local Anæsthesia, best quality, packed	1.00
NASAL DOUCHE, No. 6, See Fig. 6.	2.00
NASAL DOUCHE, for Treating Diseases of the Nasal Cavity, eight different varieties, each with two Nozzles, packed	$1.20, 1.50, 1.75, 2.00 and 3.50

N. B.—To save collection expenses, funds should be sent with the order, either in form of draft, post-office order, or registered letter.

[For complete illustrated price-list of Apparatus, Tubes, &c., see Pamphlet.]

Will be sent by mail (post-paid) on application, a Pamphlet containing two articles, by distinguished foreign authority, on

"INHALATION OF ATOMIZED LIQUIDS,"

With formulæ of those successfully employed.

Also an article by Dr. J. L. W. THUDICHUM, M.R.C.P., on

"A NEW MODE OF TREATING DISEASES OF THE NASAL CAVITY."

WITH HIS FORMULÆ.

Also, an illustrated description of the *best apparatuses* for the above purposes, and for producing Local Anæsthesia by Atomization with Ether, by the method of Dr. RICHARDSON, of London; or with Rhigolene, as described by Dr. HENRY J. BIGELOW in the *Boston Medical and Surgical Journal*, of April 19, 1866.

All our Atomizing Instruments are made with the utmost care with a view to their complete efficiency, convenience, and durability, and every one is warranted. A Gold Medal has lately been awarded us, by the Middlesex Mechanics' Association, for Atomizing and Surgical Instruments, as will be seen from the following report, signed by a leading New England Surgeon and Physician:

"**1503. Codman & Shurtleff, Boston, Mass. One case Surgical Instruments and Atomizers.**

"The Committee have no hesitation in awarding for this superb exhibition the highest premium. * * * * * The various other instruments for Inhalation of Atomized Liquids, and for Local Anæsthesia, were all apparently faultless, both in design and workmanship. The exhibitors are regarded as more especially deserving of the highest token of merit for having produced nothing except of their own manufacture.—Gold Medal.

"(Signed,) GILMAN KIMBALL, M.D., *Chairman*."

Also, by the Mass. Charitable Mechanics' Association—Exhibition of 1869—A SILVER MEDAL, the *highest medal* awarded for Surgical Instruments.

ALSO FOR SALE,

*Cammann's Stethoscopes:—	
Disarticulating	$7.00
With Adjustable Ear Pressure	8.50
*Knight's Modification	9.50
Simple Throat Mirrors	1.00
Ophthalmoscopes, Liebreich's	5.00 to 7.00
Holt's Dilator, improved	20.00
Barnes' " set of three, with Inflator and Stopcocks	7.00
Large Ear Mirrors, Tröltsche's	4.50 to 5.00
Hypodermic Syringes	3.00 to 14.00
*Miller's Intra-Uterine Scarificator, in case, (post-paid)	7.00
Lente's Intra-Uterine Caustic Instruments	1.25 to 3.50
Sponge Tents, plain and carbolized, each	.25
*Dr. Cutter's Retroversion and other Pessaries	3.00
French Rubber Urinals, with valves, male, for night or day	$6.00
Male, day only	2.50 to 4.00
French Rubber Urinals, female, for day only	3.00
Vaccine Virus, warranted, 10 quills	1.50
1 Crust	3.00
*Vaccinators, Whittemore's Patent Automatic, for Crust or Lymph fresh from arm,—Insiantaneous, certain, and almost painless (post-paid)	3.00
Powder Syringes	2.00
Laryngoscopes, complete	18.00 to 23.00
*Dr. Oliver's Laryngoscopic Lantern	4.00
The same with Auto-Laryngoscopic Attachment	5.00
The same with ditto and three Laryngoscopic Mirrors, in case	9.00
Dr. H. R. Storer's Combined Speculum	6.00

* *Send for Descriptive Circular.*

Amputating, Trephining, Exsecting, Pocket, Dissecting, Throat, Ear, Eye, Uterine, Obstetric, and all other special and general sets of Instruments on hand and made up to order.

Trusses, Spinal and Abdominal Supporters, Shoulder Braces, Suspensory Bandages, Elastic Hose, Medicine Trunks and Pocket Medicine Cases, Otoscopes, Endoscopes, Dr. Sayre's Splints for Hip-Joint Disease, Fever Thermometers, Respirators, Syringes, Crutches, Universal Syringes, Galvanic Batteries and Apparatus, French Conical and Olive-tipped Bougies and Catheters. Skeletons, Skulls, and Anatomical Charts on hand; Manikins, Anatomical and Pathological Models imported to order; prices on application. All Instruments, Implements, and Materials used by Dentists, always on hand. Apparatus for Club Feet, Weak Ankles, Bow Legs, Spinal Curvature, and other deformities, made to order.

Apparatus for Paracentesis Thoracis, approved by Dr. Bowditch, and accompanied with directions kindly furnished by him.

Having our Manufactory with steam power, and a corps of experienced workmen connected with our store, we are able promptly to make to order new instruments and apparatus, and to supply new inventions on favorable terms.

INSTRUMENTS SHARPENED, POLISHED AND REPAIRED.

Familiar Science.

LIGHTNING-RODS.

There is much doubt felt and expressed by owners of buildings respecting the full measure of protection alleged to be secured by the use of "lightning-rods." It is asserted by many that the hazard is increased by the employment of rods, and that more buildings are injured with than without them. Of course these opinions and prejudices are entertained by those who do not claim to have any special knowledge of electrical science, but are influenced by what they hear and read. The confusion and doubt which prevail are largely due to the absurd statements and claims of a class of men known as "lightning-rod peddlers," who, at the commencement of every warm season, start out from our cities with wagons filled with rods of iron, copper, steel, etc., and bushels of glass "insulators," "gold-tipped points," and all kinds of strange and whimsical devices to excite the wonder and secure the confidence of the people in the rural districts. These men are drilled by their employers, the owners of new patents, to talk glibly about "electrical fluids," "discharges," "insulation," etc., and to depreciate every device but their own. Many house-owners have been so influenced by these charlatans, as to be led to remove from their buildings rods to the extent of a half dozen different kinds in the course of as many years. The expense, annoyance, and doubt thus created are detrimental to the interests of property holders and to the cause of correct science. The careful decisions of science at the present time respecting lightning-rods, may be presented as follows:—

1st. Rods correctly constructed and applied to buildings afford nearly, if not quite, perfect protection.

2d. The kind of rod most efficient is essentially like the one which was suggested by Dr. Franklin nearly a hundred years ago, and which is now often seen upon old buildings. It is made of iron, from three quarters of an inch to an inch in diameter, and is continuous, without joints, "insulator" attachments, or a multiplicity of "points." This rod can be made by any blacksmith, and put up without assistance from peddlers or lightning-rod patentees. It may be fastened to the building by iron eyes, painted black to preserve from rust, and have a sharp platinum point for a termination above the chimney, or gable. One is enough for an ordinary sized house; for large buildings, like barns and stores, two may be used.

3d. The earth connection of the rod is a *very important* matter. If there are gas or water pipes near the building, have the rod securely fastened to a band of copper, and let this pass around the iron pipe. If there are no pipes at hand, have the rod terminate in a well, or if that is not accessible, dig a deep hole in the earth, so as to reach permanent moisture, pour in a bushel of charcoal, and carefully bury the end of the rod in this. Three or four copper, points may be affixed to the end, radiating horizontally. This form of conductor accords with the principles of electrical science as at present understood.

ABOUT QUICKSILVER.

In adapting material things to the uses of man, it was doubtless regarded as necessary that one mineral substance should be constituted so as to remain in a *liquid* state under all ordinary conditions. The metal thus provided for us is quicksilver or mercury. We remark that it is liquid under *ordinary* conditions of temperature, for it should be understood that under extraordinary conditions, *all* metals are liquid. It is well known that the atoms of iron, steel, copper, platinum, etc., which are associated in heavy, refractory masses, are not so immobile, or fixed, as they appear to be, for when submitted to high temperatures they run like water. Subject quicksilver to a temperature sufficiently high to render iron *liquid*, and it instantly becomes *vapor*, and will float away like steam. Iron, when subjected to a heat capable of liquefying platinum, will itself become vaporized, and platinum in its turn is vaporized by a higher heat, and so all the metals are physically changed under the influence of heat. There is not a solid substance upon our globe, not a mineral or metal, that has not existed probably for millions of years in the aeriform state, a condition resembling steam or air. If quicksilver is carried within the Arctic Circle, it no longer remains liquid, but becomes solid, and can be hammered, like lead or copper. The ordinary temperatures under which man flourishes upon our planet, are alone favorable to the existence of this singular liquid metal. Is not design clearly discernible in this? Is it not clear, in order that certain arts and art processes of benefit to the race should be established and carried on with facility, that a heavy, dense, liquid metal, like quicksilver, was needed? Possibly the world *could* have got along without it. Our non-mercurial barometers and thermometers might have been invented, the photographic process discovered, and impalpable gold dust separated from its parent rock through some other agency. It must be admitted, however, that quicksilver has served an important, if not indispensable end, in originating and perfecting these instruments and processes. There are plenty of pretentious charlatans, who are busy declaiming against its usefulness or safety in medicine; but, nevertheless, mercury *is* a most important therapeutical agent. Like all good things, its employment, if directed by ignorance or carelessness, may result in injury rather than benefit; but wisely and judiciously used, it subserves important curative ends,—ends hardly reached by any other known agent. The popular prejudice, engendered by designing quacks, against the use of mercury in medicine, is not founded upon justice or intelligence.

The amount of quicksilver which the various mines of the world are capable of furnishing is very large,—much larger than is demanded for any purposes to which it is at present applied. The quicksilver mines of California alone could furnish fifty times more than is consumed in the whole world, and the same may be said of the old Almaden mines of Spain. The discovery of a new quicksilver mine in the United States, no matter of what extent or richness, would possess but little more value than that of a common clay bed, if it was attempted to be worked in competition with existing mines in California and Spain. The price would immediately run down to a point so low, that its extraction must cease. At present the quicksilver trade of the world is substantially an armed truce between Spain and California. By a kind of tacit understanding between the controllers of the products from the two sources of supply, Spain is allowed to furnish the London market and nearly the whole of Europe. Until within a few years it had the great Chinese market also, but California, by adroit management, has driven Spain out of the Celestial Empire, and now claims that as her territory. In the present attitude of the trade, if California should ship 10,000 flasks to London and offer it at a reduced price, Spain would ship 10,000 to New York and

down would go the price there. On the other hand, if Spain sends a ship-load to New York, California goes to London, and so very shortly the whole business would end in ruin. To maintain remunerative prices, there must be but a limited amount distilled, and there must be special markets for the products of the two rival mines. We have spoken of California as if possessed of but a single mine. This is not to be understood as literally true. California has several mines of considerable importance, but the operations of the one known as the "New Almaden," are much the most extensive. Great as are the resources and wealth of the New Almaden quicksilver mining company, they could not continue business for a single year, if they did not accede to a combination with the weaker New Idria and Redington companies. This combination now controls the production and price of quicksilver, and when they agree that it shall go higher or lower, it fluctuates accordingly. It is, however, for their interest to keep the price uniform, and not unreasonably high, and so there is found but little variation in quotations in the great central markets.

The total annual supply from California is not far from 50,000 flasks, or about 3,000,000 pounds. This is used in metallurgy, manufacturing, and art processes. The largest quantity is used by the gold miners in the amalgamating process at the various mines. A considerable amount is used by manufacturing chemists in preparing calomel, "blue pill," mercurial ointment, and various mercurial salts and plasters. The Chinese make from quicksilver that beautiful pigment, *vermilion*, which is so largely employed by painters and colorers, in all parts of the world. It is singular that this half-civilized people are able to prepare a chemical compound from quicksilver, which is superior to, and which commands a higher price than the same salt produced in Europe and the United States, where the arts are carried to the highest perfection. English and American vermilion, as found in the market, is far inferior in brilliancy and quality to the Chinese.

One of the most curious properties of quicksilver is its capability of dissolving or of forming amalgams with other metals. A sheet of gold foil dropped into quicksilver, disappears almost as quickly as a snow-flake when it falls into water. It has the power of separating or of readily dissolving those refractory metals which are not acted upon by our most powerful acids. The gold and silver miners pour it into their machines holding the powdered gold-bearing quartz, and although no human eye can detect a trace of the precious substances, so fine are the particles, yet the liquid metal will hunt it out, and incorporate it into its mass. By subsequent distillation it yields it into the hands of the miners, in a state of virgin purity. Several years ago, while lecturing before a class of ladies upon chemistry, we had occasion to purify some quicksilver, by forcing it through chamois leather. The scrap remained upon the table after the lecture, and an old lady, thinking it would be very nice to wrap her gold spectacles in, accordingly appropriated it to this purpose. The next morning she came to us in great alarm, stating that the gold had mysteriously disappeared, and nothing was left in the parcel but the glasses. Sure enough, the metal remaining in the pores of the leather had amalgamated with the gold, and entirely destroyed the spectacles. It was a mystery, however, which we could never explain to her satisfaction. There is much that is interesting in the history and nature of quicksilver, but we have not space at present for its further consideration.

THE STEREOSCOPE.

A FRIEND, who was interested in the article on the stereoscope in our February number, has sent us a well-written communication in which he discusses certain points in the theory of the instrument more fully than we did. To insert it, however, would be giving more space to the subject than we can afford at present. In these brief papers on "familiar science," an exhaustive treatment of any topic would be impossible. All that we aim to do, all that we *can* do within the limits we fix for ourselves, is to give the main facts and principles in a familiar way. To attempt more would be to defeat our own purpose, which is to interest and instruct the many who have had no special training in even the elements of science. We address unscientific readers, not scientific students. If, as not unfrequently happens, these familiar outlines of a subject awaken a desire to know *all* about it, we have simply prepared the way for a more thorough course of scientific reading or study. If the inquirer wants us to refer him to the best *books* for his purpose, we are always happy to do so, but we cannot make the JOURNAL a substitute for the books.

In reply to those who have asked us what *form* of stereoscope is best for common use, we would say that the one devised by Dr. Holmes, and improved by Mr. J. L. Bates, of Boston, is unquestionably superior to any other pattern. A little more than a year ago, one of these instruments got into English hands, and was exhibited at the meeting of a photographic society in London as "a very ingenious stereoscope of American manufacture, combining completely all the excellences of the most expensive instruments." The *British Journal of Photography* devoted two articles and a cut to the "Yankee notion," but the editor evidently had not heard who invented it. This was rather funny, as it had been familiar in this country since 1861. In July of that year Dr. Holmes referred to it in an admirable article on "Sun Painting and Sun Sculpture," in the *Atlantic Monthly;* and a detailed history of it may be found in the *Philadelphia Photographer* for January, 1869, in a racy letter from the "autocrat" drawn forth by this British "discovery" of his seven-year-old invention.

As neither Dr. Holmes nor Mr. Bates took out patents for their improvements in the stereoscope, this form of the instrument is now made by many parties. Owing to the use of bad lenses, or bad adjustment of tolerable ones, not a few of these instruments are regular "eye-twisters." A perfect stereoscope should cause no more trouble to the eyes than looking through good window-glass.

Occasionally we meet with stereographs, the halves of which are misplaced — the right-hand picture put on the left side, and *vice versa*. If the reader remembers what we said in our former article concerning the difference between the two pictures, he will readily see that they are misplaced if he examines them closely. In such a case, of course, he has only to cut the stereograph in two, and transpose the halves.

FORCE, THE EQUIVALENT OF MATERIAL MOTION.

THAT the chemical molecules of all substances have a definite and determinable motion which is the source of that form of force which we call heat, is sufficiently evident from the law of *Petit* and *Dulong*, which, when the necessary eliminations are made, may be regarded as rigorously exact, and is therefore accepted as the basis of a *mechanical theory of heat;* the law may be announced as follows: —

The specific heat of all substances multiplied by their respective atomic weights is a constant quantity.

If we accept the sensation of heat as the manifestation of otherwise inappreciable molecular motions, it is not difficult to form a rational conception of it as a form of force readily convertible into sensible motion, or mechanical force. And as, through the agency of the steam-engine, heat is now employed as the principal motive force throughout the civilized world, and, moreover, as heat and light are the motive forces from which result all, or nearly all, *natural* phenomena which come under our observation, including the growth and decay of vegetable and animal organizations, it is interesting to trace the material motion of which they are the indications, through the whole, or even through a part of its cycle of changes.

It would obviously be absurd to attempt to assign a rational *cause* for the *origin* of matter; and in like manner it would be absurd to attempt to assign a cause for the *initiation* of motion. We accept the existence of both matter and motion as a primal fact, and cannot imagine as possible either their coming into existence or their going out of existence. Visible matter may, and frequently does, escape ordinary observation, and may yet be proven to be present and undiminished in quantity; and in like manner sensible motion may disappear and yet, from the principle of the conservation of forces, we *know* that it continues undiminished in quantity.

The essential characteristic of matter is *inertia*, and its universal condition is *motion*. It follows from the conservation of forces that the same amount of motion that now exists in the universe, always existed, and always will exist. Contiguous portions of matter may be *relatively* either in motion or at rest, yet the sum-total of motion is, and forever must be, invariably the same.

The recognition of a universal non-gravitating ether which is capable, as the luminiferous ether is known to be, of imparting motion to, and of receiving motion from, the molecules of ponderable matter, enables us to comprehend the *apparent* annihilation of motion, and to understand that

what appears to be destruction of motion is only a transfer from a tangible form to an intangible form of matter.

When, for instance, the atmosphere radiates its heat into space, the motion which constitutes the heat is not *destroyed* or lost, but is transferred to the universal ether in space; and as the tension of this universal ether is so great that a wave is transmitted through it with a velocity of two hundred thousand miles per second, it is obvious that no amount of local radiation to it can sensibly affect the *amount* of motion, in even a limited portion of the ether, for any considerable period of time.

Not only is the ether which pervades infinite space eternally in motion, but the molecules which constitute every form of tangible matter, as we have already remarked, are proven to be in constant and rapid motion among themselves, each substance having molecular motion peculiar to itself. Two substances having dissimilar molecular motions may therefore be brought in contact so that their molecular motions shall *interfere*, and a compound molecule will result, the motion of which will be *less* than the sum of the motions of its constituents. This difference of motion is *not* so much motion *destroyed*, but it is so much motion *transferred* to the surrounding medium, and manifests itself in the form of heat in contiguous bodies. And this heat, if developed in a suitable body, as in aqueous vapor, for instance, or in any permanent gas, may, through the agency of the steam-engine, be converted into mechanical force; or, through the agency of vegetable or animal organizations, into the *vital* forces.

All forms of force, therefore, or at least the mechanical and vital forces, result from molecular motion, and are the equivalents of the *inertia* of the molecules multiplied into their *velocities*.

J. E. Hendricks.

Des Moines, Iowa.

HENRY CAVENDISH,

OR HOW A CHEMIST LIVED AND DIED.

A correspondent of the *N. Y. Observer* gives some interesting facts concerning that great but eccentric philosopher, Henry Cavendish. He was the son of an English nobleman, born in 1731, and living a retired life, known only by such men as Sir Humphrey Davy and Lavoisier, and to them only by his brilliant discoveries, and on his death leaving more than a million sterling to his relatives. We make the following extracts from the article in the *Observer*: —

HOW HE LIVED.

"Cavendish House still stands in Clapham, and when the writer visited it, twelve years ago, remained as its owner left it nearly half a century before. In external appearance it was the mansion of an English gentleman. One sees a thousand like it. But to its arrangements within, the whole world could not, perhaps, furnish a parallel. Anvils and forges, files and hammers, grindstones and tempering troughs, furnaces and huge bellows, had converted the paneled and wall-frescoed drawing-room into the shop of a blacksmith. In the spacious dining-room chemical apparatus occupied the place of furniture. Electrical machines, Leyden jars, eudiometers, thermometric scales and philosophical instruments, were distributed through the chambers. The third story, save two bedchambers — one for the housekeeper, the other for the footman — had been fitted up for an observatory. The lenses and achromatic glasses, tubes and specula, concave mirrors and object prisms, and the huge telescope peering through the roof, were still there as their owner had left them. Furniture there was not. All appliances of housekeeping were absent. Comfort, as we understand it, was no element of life in Cavendish House. It was the residence, simple and pure, of a philosopher. It is said of the eccentric occupant that he was so shy of the female sex as instantly to dismiss any chambermaid who appeared in his presence, and that he ordered his dinner daily by a note to the housekeeper left on the hall table.

"At the age of forty, a large accession came to his fortune. His income already exceeded his expenditure. Pecuniary transactions were his aversion. Other matters occupied his attention. The legacy was, therefore, paid in to his bankers. It was safe there, and he gave it no more heed. One of the firm sought to see him at Clapham. In answer to the inquiries of the footman as to his business, the banker replied that he wished to see Mr. Cavendish *personally*. 'You must wait, then,' responded the servant, 'till he rings his bell.' The banker tarried for hours, when the long-expected bell rang. His name was announced. 'What does he want?' the master was heard to ask. 'A personal interview.' 'Send him up.' The banker appeared.

"'I am come, sir, to ascertain your views concerning a sum of two hundred thousand pounds placed to your account.'

"'Does it inconvenience you?' asked the philosopher. 'If so, transfer it elsewhere.'

"'Inconvenience, sir? By no means,' replied the banker; 'but pardon me for suggesting that it is too large a sum to remain unproductive. Would you not like to invest it?'

"'Invest it? Eh? Yes, if you will. Do as you please. But don't interrupt me about such things again. I have other matters to think about.'"

HOW HE DIED.

"Without premonitory disease, or sickness, or withdrawal from daily duties, or decadence of mental powers, or physical disability, he made up his mind that he was about to die. Closing his telescope, putting his achromatic glasses in their several grooves, locking the doors of his laboratories, destroying the papers he deemed useless, and arranging those corrected for publication, he ascended to his sleeping apartment and rang his bell. A servant appeared.

"'Edgar,' said Cavendish, addressing him by name, 'listen! Have I ever commanded you to do an unreasonable thing?'

"The man heard the question without astonishment, for he knew his master's eccentricities, and replied in the negative.

"'And that being the case,' continued the old man, 'I believe I have a right to be obeyed.'

"The domestic bowed his assent.

"'I shall now give you my last command,' Cavendish went on to say. 'I am going to die. I shall, upon your departure, lock my room. Here let me be alone for eight hours. Tell no one. Let no person come near. When the time has passed, come and see if I am dead. If so, let Lord George Cavendish know. This is my last command. Now, go!'

"The servant knew, from long experience, that to dispute his master's will would be useless. He bowed, therefore, and turned to go away.

"'Stay, — one word!' added Cavendish. 'Repeat *exactly* the order I have given.'

"Edgar repeated the order, promised obedience once more, and retired from the chamber."

The servant did not keep his promise, but called to his master's bedside Sir Everard Home, a distinguished physician.

"Sir Everard inquired if he felt ill.

"'I am not ill,' replied Cavendish, 'but I am about to die. Don't you think a man of eighty has lived long enough? Why am I disturbed? I had matters to arrange. Give me a glass of water.'

"The glass of water was handed to him; he drank it, turned on his back, closed his eyes, and died.

"This end of a great man, improbable as are some of the incidents narrated, is no fiction of imagination. Sir Everard Home's statement, read before the Royal Institution, corroborates every particular. The mental constitution of the philosopher, puzzling enough during his life, was shrouded certainly in even greater mystery in his death."

HOUSEHOLD RECIPES.

Good Yeast. — A small handful of hops boiled in a quart of water. With it boil until done five medium-sized potatoes, pared. Now make them smooth with one and a half pints of flour. Pour in the water strained from the hops. Stir this until it is a thin batter, adding hot water if too thick. Let it stand until little more than milk-warm, then add a teacupful of good brewer's yeast. Let it stand in a warm place eight or ten hours, when add a tablespoonful of salt and two of white sugar. Mix well, set it away in a stone jar or jug, and it is ready for use.

Washing Fluid. — The following has been tested for more than five years with perfect satisfaction. Dissolve $1\frac{1}{4}$ pounds of washing soda and $\frac{1}{4}$ pound of borax in a gallon of water, by boiling. When the solution is cold, add about half a teacupful of aqua ammonia (spirits of hartshorn), and put it up in well-corked bottles. Use a cupful to each pailful of water in washing.

Tomato Ketchup. — The following recipe is highly commended, and will soon be "in season:" —

Tomatoes	$\frac{1}{2}$ bushel.
Salt	6 oz.
Allspice, ground	6 drachms.
Yellow mustard, ground	1 oz. $5\frac{1}{2}$ drachms.
Black pepper, ground	3 oz.
Cloves, ground	6 drachms.
Mace, ground	3 drachms.
Cayenne pepper, ground	2 drachms.
Vinegar	1 gall.

Cut the tomatoes to pieces, boil and stew in their own liquor until quite soft. Take from the fire, strain, and rub through a middling-fine hair sieve, so as to get the seeds and shells separated. Boil down the pulp and juice to consistency of apple butter (very thick), stirring all the time; when thick enough, add the spices, stirred up with the vinegar, boil up twice, remove from the fire, let cool, and bottle.

Fly Poisons. — The following will kill the flies, but not the babies that happen to get hold of them:

1. Boil a quarter of an ounce of small quassia chips in a pint of water. Strain, and add a gill of molasses.

2. Mix together one part of black pepper, two of brown sugar, and four of cream.

English "Ginger Pop." — This popular British beverage is made as follows: One and a half ounces of the best ground Jamaica ginger, one ounce of cream of tartar, one pound of sugar, and two sliced lemons: to all of which add four quarts of boiling water, and a half pint of yeast; let it ferment for twenty-four hours, strain and bottle it. In a week or two it will be ready for use.

Bottling Fruit Juices. — A certain amount of sugar is dissolved in the juice of the fruit, the white of an egg added then to each gallon of solution, and the whole heated to boiling. The froth which will rise, and which will contain all the impurities, is removed by means of a spoon, and the clear fluid boiled down, until it contains about two pounds of sugar to the quart. It is then mixed with half an ounce of sulphite of lime to the gallon, when, after bottling in the ordinary way, it will keep for a year and longer.

The Arts.

NEW THINGS IN THE ARTS.

Green Dyes. — Although green is the most common color in the vegetable world, science has not succeeded in obtaining a green dye-stuff from plants. It is well known that the green color of leaves is due to a compound called *chlorophyl*, but this substance has not been obtained in a form practically useful. There are aniline dyes which afford a green directly, but, with this exception, the color is produced in an indirect way by mixtures of yellow and blue. It appears, however, that the Chinese prepare a green dye, called *lo-kao*, from the bark of a species of *rhamnus*, or buckthorn, which from its behavior is considered to be identical with *chlorophyl*. The European consuls in Chinese ports have obtained some information with regard to the manufacture and use of this substance, and a silk-dyer of Lyons has shown that a similar compound can be got from European species of *rhamnus*, but in such small quantities that it will hardly pay to extract. Experiments made at Lyons with the Chinese dye prove that it can be used to advantage in spite of the exorbitant price — about $107 a pound — which the natives charge for it. The green color obtained from it shows even better by artificial light than by day. As sunlight is a requisite in the preparation of the dye, it is likely to prove a very fast color under exposure to the air and the sun.

Household Steam-Engines. — We may yet have steam-engines to do our kitchen work, and the "servant girl question" may thus at length find a satisfactory solution. We learn from *Les Mondes* that engines of *one tenth horse-power* (about one "Biddy" power) are made by Mignon and Rouart, 149 rue Oberkampf, Paris. This power is obtained with a consumption of 700 litres of coal gas (which is equal to 600 grammes, or about 21 ounces, of coal) per hour. Over a hundred of these little machines are in use, and their owners bear testimony that they work well. Cannot our Yankee inventors get up something of the kind? Such engines would soon be in great demand for mechanical purposes, where a small power is required, and we do not see why every household should not come to have its steam-engine to help out in many kinds of domestic labor.

Preservation of Wood from Fire and Decay. — Dr. Reinsch, whose name has for some time been associated with investigations of this kind, renders wood (which must be unplaned) non-combustible by the following process: It is first soaked for twenty-four hours in a solution of 1 part of silicate of potassa in 3 parts of pure water. After being dried for several days, it is again soaked in this liquid, and again dried. It is then painted with a mixture of 1 part of cement and 4 parts of the liquid just described. Three such coats of paint are put on, each being thoroughly dried. The paint should not be prepared in large quantities at once, as it soon becomes dry and hard. Wood thus treated is not only incombustible, but will not decay underground.

Preserved Meat. — At a lecture in Vienna, last month, Dr. Stein showed a large tin canister containing butcher's meat preserved by Appert's method, and prepared by himself in 1851. On opening it, the meat, though nineteen years old, was found to be as fresh and as well-flavored as when it was first put up.

The "Paper Age." — *Appletons' Journal*, commenting upon the new applications of paper mentioned in our last number, says: —

"But if petticoats and table-cloths, curtains, etc., can be made of paper, if a material like leather can be produced from this substance, why may we not expect in time to have our coats and trousers made of it? Why may we not be able to go about 'paper clad' — with paper hat, in paper shoes, with paper coat and trousers, furnished without in paper, and fortified in our pocket-books with Uncle Sam's good-looking paper money? The cost, moreover, of such an outfit [without the pocket-book] would be so trifling that luxurious people could have an entire new suit every day, and even economical persons adorn themselves afresh as often as once a week. The 'paper age' promises to revolutionize our social habits in not a few particulars."

A New Use for Water-glass. — Silicate of soda is now used to restore the leather coverings of machine cards and cylinders to their original smoothness and pliability, after they have been long in wear. The surface thus renewed is much more lasting than that obtained by means of gum arabic and similar substances.

To Incrust Window-glass with Jewels. — Dissolve dextrine in a concentrated solution of sulphate of magnesia, sulphate of zinc, sulphate of copper, or other metallic salt. Strain the liquid, brush a thin coat of it over the glass, and dry it slowly at the ordinary temperature, keeping the glass level. This coating will bear some rubbing. It may be varnished with any alcohol varnish, to protect it. The effect produced is that of an incrustation of diamonds, sapphires, etc., according to the color of the salt used.

WHAT THE WORLD WEARS.

Fur, cotton, wool, and silk are the chief materials out of which clothes are made. Prof. Vater, in a lecture on "Clothing," suggested that it would be interesting to indicate by colors upon a map the distribution of these over the earth. If we use brown for the regions where fur and leather clothing is used, about half of the habitable globe would bear that color, for these materials prevail in Siberia, Northern Europe, two thirds of North America, and the Southern extremity of South America, and as they indicate at the same time the lowest degree of civilization, it would also show to what a small portion of the world higher culture is restricted. The color for animal wool would occupy the next largest space; if we select yellow for this, all Europe, the Cape of Good Hope, and the United States of America, as far as they are inhabited by the Caucasian race, and the similarly populated parts of Australia, would have to be dyed yellow. It is evident that this includes the most enlightened nations of the world. The domain of cotton, which we may color with purple, will be of about the same extent; embracing a great part of China, both Indies, Persia, Asia Minor, the whole coast of Africa, with the exception of the Cape, Mexico, Central America, and the coasts of Brazil, Peru, and Chili. Cotton would indicate the second rank of civilization. All the other fibres used might be designated by a fourth color, say by green, and with it we should have to mark the silk districts of China and the entire interior of Africa and Australia; though these last might be left uncolored, as the people wear little or no clothing of any kind.

Roman Remains in Paris. — Several months ago, we spoke of the ruins of the old Roman baths (known as the *Palais des Thermes*) as the oldest building in Paris. The remains of the amphitheatre since discovered in the *rue Monge*, are considerably more ancient, dating back to the first half of the third century. The edifice was 142 yards in diameter, and could contain 15,000 spectators. The portions of the foundation now brought to light, are built of stones beautifully hewn and fastened together with Roman cement. Stone cages for wild animals have been uncovered, in perfect condition; and slabs of stone are found bearing the names of the patrician families who owned the seats, or "boxes." Among the things discovered in and about the ruins, are articles of jewelry; pins of iron, gold, and bronze; fragments of sculptured marble; glazed and painted pottery; bronze and silver medals of Hadrian and other emperors; urns, vases, etc.; and several skeletons. The government has already taken measures to preserve this interesting relic of ancient days.

MANUFACTURE OF NITRO-GLYCERINE.

In the manufactory of M. Mowbray about 150 litres (33 gallons) of nitro-glycerine are produced daily. The apparatus employed is a large horse-shoe reservoir, of about three feet in height and fifty feet in length, which is filled with a refrigerating mixture of ice and common salt. In this tank are placed, at a distance of two feet from each other, stoneware vessels of 4 to 5 litres capacity, the necks projecting about 2 or 3 inches only above the freezing mixture. The mixture of nitric and sulphuric acids is poured into the vessels, and the glycerine made to enter, drop by drop, from a reservoir placed two feet above the earthenware jars. To agitate the mixture M. Mowbray employs cold air. For this purpose a glass tube is plunged into each vessel, and by a caoutchouc tube and tap, is placed in communication with cold compressed air. When the reaction occurs, the temperature rises, and red vapors are evolved; the workman moves the glass tube through the mass of liquid, which, being traversed by the current of air, is promptly cooled, at the same time that the nitrous vapors are carried off.

Forty-two kilogrammes of glycerine yield ninety-four kilogrammes of nitro-glycerine. The product is perfectly limpid and colorless at 9° C.; below this temperature it is congealed, and then resembles bruised ice, in which state it is not explosive, and can be transported without danger. M. Mowbray's nitro-glycerine dilates by congelation, while the ordinary nitro-glycerine contracts under the same conditions; this is explained by the presence of vapors of hyponitrous acid in the latter, which are absent in the former.

Agriculture.

SHORE PENCILLINGS AT LAKESIDE, NO. 1.

As we sit in the shade of the trees on the shore of the beautiful Kenosa at Lakeside, we take our pencil and put upon paper the thoughts upon nature, rural life, agriculture, horticulture, etc., which naturally come to us while thus at rest and alone. We are not quite alone, however, for we have the pleasant company of the birds and the squirrels that flutter and chirp about us. How beautiful is this scene upon this glorious June morning! The lake shimmers and sparkles in the light, as the sun climbs the opposite hills and pours its slanting rays through the rich foliage upon the peaceful waters. The sky is of the deepest blue, and the earth is carpeted with the intensest green. Wild flowers are scattered in profusion everywhere; the buttercups and the dandelions with their tints of yellow, blending with the green, give to the landscape a richness of coloring which no painter can imitate. The drops of dew, not yet dissipated by the warmth of the sun, rest upon the grass and the shrubs, and glisten like the purest gems. The transparent waters of the lake afford to the eye a clear look into its depths, and its pebbly bottom is seen far away from the shore where we are sitting, and we can watch the movements of the perch and pickerel foraging for their morning meal. The earth is in its holiday attire; the waters, just escaped from the icy bonds of winter, are joyous as an infant when it awakes from the sweetest slumber; the air is laden with the odors of flowers and the songs of birds. Rest, rest, peaceful rest — of this let us have our fill. Let us forget the city, its noise and dust, and the bargainings and wranglings of restless men; let us commune with Nature, study her lessons, observe her laws, and thus be made wiser, happier, better. A friend from the city the other day, lounging by our side under the trees, asked if we did not think that those who were permitted to enjoy much of rural life would have some deductions made from the happiness of the life beyond. This was a random thought presented in jest, and prompted doubtless by the satiety of enjoyment which those only feel who emerge for the first time from winter life in the city. Such excursionists into the country have rather exaggerated notions of the inequality with which enjoyment is distributed among men, and their estimate of the pleasures of rural life is based upon the brief hour they pass under the trees. The difference in amount of absolute enjoyment in this world is very much less than is supposed. Every man regards his neighbor as having at his command sources of happiness denied to himself. The poor man envies the stately mansion, the horses and carriages, and the luxurious table of the rich. The rich man would give all his possessions to buy the health, the sweet slumber, and the freedom from care that his poorer neighbor enjoys; and so we recognize the wisdom of Providence in establishing the immutable law by which happiness is meted out in about equal measure to all who seek it with pure motives.

Happiness depends much upon the sensibilities, and very much upon how we educate ourselves We may live in the midst of the most beautiful manifestations of nature, and through insensibility or sordidness, be incompetent to enjoy them. It is true, also, that in order to enjoy city or country life, it is necessary that we experience some of the toils, inconveniences, and vexations of both and be able to escape from the one or the other at will. By contrast with the brick walls and the hurly-burly of the city, the country seems a paradise; but for those tied to the country, and compelled to toil in the fields, the city possesses extraordinary attractions. From our present point of view rural life appears beautiful, and the language of poetry is quite inadequate to describe the peacefulness and delights of the scene. *We* are under the trees, with the glorious lake before, and the farm behind us. Over yonder, in the meadow, is Mike, a genuine Hibernian, in a straw hat, and a striped shirt with sleeves rolled above the elbows, showing brawny arms, which under the influence of sun and air have acquired a hue like that of hemlock-tanned leather. He has milked his tenth cow this morning, and driven the herd to the hill pasture, where they are now busily at work nipping the white clover blossoms fresh with dew. We have sent him to the meadow to pull up by the roots some burdock plants, the seeds of which during the winter washed in from the highway. Mike declares this to be "sweaty work," and "terrible for the back." From the experiment of extracting a half dozen of the long-rooted plants, we conclude he is more than half right.

Let us "interview" Mike and learn his opinion regarding rural life, farm work, etc. "Well, Mike, this is a fine morning; what a happy fellow you must be, out here in the green meadows, with the birds making music for you, and the winds filling you so full of sweet scents as even to mask the odor of that old pipe, the stem of which has found its way out through a hole in your pocket. Tell us, Mike, what you think of these beautiful scenes, and farming matters in general." "Indade, sir, the mornin' is a fine one, to be sure, but I haven't heard any birds; and as to the air, it is good enough, what there is of it, but if there was more of it 'twould cool me off a bit; and as to the scents, they don't trouble me. Farming, sir, is hard work, airly and late, dig, dig, all the time; what with the cows, and the milkin', and the weeds to pull, and corn to hoe, there is small time to take a whiff from the ould pipe. Fine gintlemen, that can lie on the grass all day, don't know what farming work is, beggin' your pardon, sir, for bein' so plain with you."

And Mike's plainness is excusable. He don't hear the birds sing. nor smell the sweet odors of flowers. A plug of tobacco has a more grateful fragrance to him than buttercups or violets; and as to the air, it is only fine, when there is enough of it to cool his sweaty brow. A visit to the city, after haying, is an event to which he looks forward as the one great thing in the future. But after all, Mike is happy; he has but few wants, and fewer cares. If his back aches at night, from using the hoe, or swinging the scythe, it is "all right" in the morning after six hours of sound slumber. Although insensible to the beautiful things in nature, compensation is made for this, in the harmony with which the physical mechanism works, and in the robust health enjoyed, and in the narrowness of the world in which he moves, which affords no scope for ambition, and gives rise to but few artificial wants.

But our pencil wanders off upon topics which we can as well consider when the frosts are upon us, and the light from the winter fire dances upon the parlor walls. Let us turn our eyes towards the farm, and notice what the warm sun and the rains are doing for the crops. The rye field, although a small one, is indeed magnificent in its luxuriance. Yesterday the rule was applied to the stalks, and many of them were found to measure quite six feet and a half. This is pretty well for winter grain upon the first of June. We think the average height would be six feet, so perfect and uniform is the growth. The corn is up, and looking green and vigorous. It is now being subjected to the first weeding process. Potatoes, we are sorry to say, fail with us. We have laid our neighbors and friends far and near under contribution for varieties of seed, but at harvest time it is all the same. Every variety takes the disease, and a month or two after being dug, they are but a filthy mass; and so we strike potatoes from our list of crops. The grass never looked better, and it is hardly possible for anything to occur now which will prevent farmers from turning a heavy swath in July. The reclaimed meadow, upon which we have not allowed an ounce of barn-yard manure to be placed, is thick with verdure, and a crop of three tons to the acre may reasonably be expected. Three years ago the product of this field was not worth a single dollar. The experimental field of one acre, upon high land, which has been for seven years nourished solely by chemical fertilizers, is promising us an abundant yield. No acre at Lakeside has given such rich returns for the amount expended upon it as this.

The show of fruit is really wonderful. The spring has been like one of those old-fashioned seasons, when apples and pears hung from every bough, and the farmer was obliged to bring out his stakes and prop up his over-burdened trees. But a cloud rests upon our apple prospects. The terrible canker-worm has made its appearance at Lakeside, and the filthy thing can be seen spinning down from the limbs, and the green leaves are blasted as it were by fire. We hope our six hundred beautiful trees, loaded with fruit, will not be entirely destroyed, this season. The grapes and pears are in fine condition. The vineyard of Concords and Delawares is full of blossoms, and the vines never looked better. Five years ago, when it was planted, the ground was dressed liberally with a compost composed largely of bone dust and ashes, and no fertilizing substance has been since applied. We shall wait and see how soon the vines will falter under this treatment. The prospect for abundant harvests of all the grass, cereal, and fruit crops was never better, and let us hope that nothing will occur to blast our pleasant anticipations.

GRAPE VINES ON THE STUMP.

Dr. Channing gives, in the *Providence Journal*, an interesting *resumé* of William J. Flagg's book, "Three Seasons in European Vineyards," recently published by the Harpers. The object of Mr. Flagg is to awaken an interest among our grape growers in the new method of training vines which is practiced in Europe. We do not know how far this system may be adopted with advantage in this country. It is important that the method should be understood, and the system thoroughly tried by competent vine cultivators.

"The *souche* culture of the vine converts it into a shrub in summer, and into a stump smaller than a cabbage in winter. No stake or trellis is ever required. Two or three shovelfuls of earth, in the autumn, cover out of sight a vine twenty years old. Three fourths of the labor and expense of the present method of cultivation are saved.

Souche training is no mystery. At the end of the first year the young vine is cut back to a stump about nine inches high, leaving at its top, if possible, two canes reduced each to two eyes in length, which are to become permanent arms of the future *souche*. At the end of the second year the pruning is so performed as to give to this stump of nine inches, from three to six short arms. At the end of the third year the *souche* is so trimmed as to increase the number of short arms to six, if that number has not been previously obtained. The pruning is subsequently uniform, year by year, leaving one or possibly two canes of the preceding year's growth (cut back to one or two eyes each) at the end of each arm. Care is taken to balance the souche on all sides by symmetrical arrangement of the arms. When too much old wood accumulates upon them they are carefully cut back so as to restore the original compact form.

The greatest product is obtained from vines *en souche* when they are set out five feet apart in each direction, (1,600 plants to the acre.) This allows the plough and cultivator to be used in field culture. One precaution needs to be observed. This is seasonably to remove the suckers which spring up around the stump. The ground should also be kept clean of weeds. The winter trimming is rapidly done by shears. The European practice of progressively stripping the vine of leaves to aid the ripening of the grape is not adapted to our climate. Even the pinching in of the growing canes and laterals has been probably carried to excess in New England.

The grape vine on the stump can be cultivated in the garden, wherever a raspberry or blackberry can be set. Mr. Flagg especially recommends for the souche our short jointed varieties, carrying stiff canes. The trimming and perhaps height of the stump will probably vary within certain limits with different varieties.

In New England and the north of the United States, *souche* culture promises the means of easy winter protection for our best varieties, which we have long needed. A mature vine, reduced to such dimensions in winter that a stove-pipe hat can cover it, can be buried out of harm's way by plough and spade with the greatest ease. The compactness of the grape, *en souche*, in summer makes it easy, also, to apply the sulphur cure (fully illustrated in Mr. Flagg's book), at the first approach of mildew or *oïdium*. The protection from extreme cold and from disease thus afforded makes it at once practicable to cultivate *en souche* in our fields many of the early ripening European varieties. Undoubtedly our Allyn's hybrid is better than the European Sweet Water or Chasselas, and the Delaware is not excelled in its class. The Crevelling and Adirondack rank high among black grapes. But all of these, and even the hardiest of our native grapes, are much benefited in this latitude by winter covering such as the *souche* invites.

The vineyards of the south of France, now occupying a million and a half of acres, have been kept from time immemorial *en souche basse*. This is true also of much of Burgundy, of Cognac, Medoc, and Sauterne.

The soils of many of the celebrated French wine districts are sandy or gravelly, and contain an unusually large proportion of lime and iron. Stones in the soil are considered no disadvantage, though natural or artificial drainage is always indispensable. Valuable grapes are cultivated sometimes on soils so poor that they will bear hardly a crop of mullens. The finest French wines come from the poorest soils, the quality being in inverse ratio to the quantity. Thus an acre hardly yields more than 150 gallons of the choicest grape juice. The yield of Medoc and the Côte d'Or of Burgundy is only 250 gallons to the acre, while in rapidly descending scale of quality are products of grape juice of 1,000, 2,000 or even 3,000 gallons to the acre. This is illustrated by the story of the vineyard of Clos Vougeot, the seat of an old monastery. From 80 acres the monks obtained only 1,200 gallons of very choice wine, the product of vines 400 or 500 years old. The French revolution dispossessed the monks, and their secular successors obtained from new vines on the same ground no less than 18,000 gallons of the poorest and sourest wine. Young, and recently manured vines are considered in France on a par, and unfit to produce good wine. In Sauterne they manure once in 3 years; in Medoc once in 7 to 10 or even 20 years. To diminish the yield and perfect the fruit, the vines are sometimes crowded to the extent of from 10,000 to 25,000 on a single acre. A common number is 4,444, that is three feet apart in each direction.

In this country we want to obtain the largest possible product of ripe grapes, but we have much to learn from European experience. Our grapes frequently remain sour and never ripen from the excessive use of stimulating manures, which induce overgrowth and overbearing. We think that young vines in New England are frequently ruined by the rich artificial soil in which they are set, or by a subsequent surfeit of animal manures. Mineral manures, such as lime, plaster, ground bone, and oxides of iron, need less caution. Not the least advantage of the *souche* is the severe compulsory winter pruning to which it will subject many of our varieties. A few varieties, like the Rogers hybrids, are perhaps too rampant for this severe treatment, but they are varieties which thrive with the least amount of care. With many varieties it will be desirable, even on the *souche*, to reduce the number of bunches one half to secure good ripening.

A WORD FROM NORTH CAROLINA.

A gentleman of distinction, a subscriber to the Journal, residing in the western part of North Carolina, writes us a letter in which he speaks enthusiastically of the beauty, healthfulness, and agricultural advantages of that section. We give a few extracts from the letter, as we think they may be of interest to our readers:—

"There are doubtless good men among the patrons of your paper who would like to help us make this western North Carolina what nature intended it should be — the home of a refined and energetic population. Massachusetts is always ready to contribute her share of men; but there is *choice* even among her sons, and I hope to have them from the class who take and read the Journal, as such must be worthy and intelligent. South Carolina has done much for this section, and scattered through the country are some of her best representatives. See to it, so far as you can, that those who come from your State compare favorably with these moulded by Huguenot influences. Only the wealthy class from the South have come here, for the region was not of easy access, and they sought it for its beauty of scenery and climate — its summer climate. Your people are just learning that it is a delightful *winter* resort.

"Whether for summer or for winter, our climate is unequalled on this continent. The scenery is magnificent. Let your New York readers just step into Anthony's on Broadway, and look at the views of this region taken by Barnard. As I write, the Black Mountains, the highest east of the Rocky, are in full view, twenty miles away, and without leaving my room, I can see landscapes more varied and more charming, than have met my eye in journeys of thousands of miles through lands famous for their beauty. Our mineral resources are immense, and the forests of oak, poplar, chestnut, mountain maple, and black walnut, are of vast extent. The water power, too, is abundant. The soil is black and rich, from the valleys to the tops of the hills, excellent for grass, or grain, or fruit. I am well acquainted with Massachusetts and New York, having lived in those States when a boy, and for thirty years I have made my home in the South, and have rode or walked over South Carolina, Georgia, Florida, and all the Atlantic line of States; and for scenery and agricultural advantages, this section surpasses all I have seen elsewhere.

"The place has peculiar attractions for the invalid, and especially for the consumptive. We are elevated some 3,000 feet above the adjacent country, to the west of the Blue Ridge, as you will see by the map. We have all the products and comforts of the Temperate Zone, while we are in the midst of a warmer region, and we thus enjoy all the advantages of both.

"To all who come among us we extend a hearty welcome, and I hope that many from your section may be tempted to come."

GLEANINGS.

To destroy insects on plants, water them with a very weak solution of phosphoric acid. While it kills the bugs, it helps the plants by adding to the soluble phosphates in the soil. It is predicted that it will come to be extensively used in agriculture.

M. Lecouteux, in *Cosmos*, gives an account of experiments made near Paris, where a daily quantity of sewage-water amounting to 6,000 cubic meters (over 210,000 cubic feet, or 6,000 tons' weight) was run over a surface of 6 hectares (nearly 15 acres) of what used to be a barren soil, which has thus been converted into a very productive market-garden. The soil absorbs and retains all the suspended matter of the water, and the experiment is every way successful.

The XIX Century, published in Charleston, S. C., in commenting upon the advertisements of some of the Northern florists, remarks:—

"Let us say just here, that all seeds, vegetables as well as flowers and fruit, have to be acclimated, and the seedsman and florist who gets the largest per cent. out of the two or three hundred millions which the South now makes in cotton, will be he who comes among us, and starts a flower farm in the heart of the South. If some flowers can be hot-housed into beauty up there, what can be done here? Our sun and soil wait for the man who wishes to make his fortune in so easy a way."

To find how many bushels there are in a box or bin, multiply the number of solid feet in the same by 45 and divide by 56. The quotient will be bushels, since one solid foot (1728 cubic inches) is $\frac{45}{56}$ of a bushel, or $2150\frac{2}{5}$ cubic inches. For example, if we wish to find how many bushels a box, 8 feet long, 4 wide, and 2 deep, will hold, multiply 8, 4, and 2 together, and we get 64, the number of cubic feet in the box; multiply 64 by 45 and divide the product by 56, and we get $51\frac{3}{7}$, the number of bushels it will hold. The rule is a simple and convenient one, and farmers should make a note of it.

Boston Journal of Chemistry.

JAS. R. NICHOLS, M. D., *Editor.*
WM. J. ROLFE, A. M., *Associate Editor.*

BOSTON, JULY 1, 1870.

PUBLISHERS' NOTICE.

All correspondence relating to the business of the Journal, remittances, etc., must be addressed, Boston Journal of Chemistry, 150 Congress Street, Boston, Mass." Mr. George S. Chase, who during the past year, has managed its business affairs, will still continue in charge of the correspondence, advertising, and other matters connected with the publishing department.

All correspondence relating to editorial affairs should be addressed to the Editor, 150 Congress Street, Boston.

THE JOURNAL GIVEN AWAY.

On receipt of the publishers' price of any one of the following riodicals, we wil send *both the* JOURNAL *and that periodical* for one ar. This offer applies to those persons only who are not already bscribers to the periodical selected.

E ECLECTIC	$5.00
ERY SATURDAY	5.00
E NATION	5.00
TURE (*London*)	5.00

OUR FIFTH ANNIVERSARY.

THE dress in which the JOURNAL appears upon its fifth anniversary, is one which we are confident will be pleasing to its patrons. It is printed from stereotype plates cast from new type, and the paper is of superior quality manufactured expressly for it. In order to secure the highest excellence and greatest accuracy, in the mechanical department of the JOURNAL, we have placed it in the hands of Messrs. H. O. HOUGHTON & Co., of the celebrated Riverside Press, Cambridge, who will hereafter both print and publish it. The business affairs of the JOURNAL are now of such magnitude as to demand the special attention of experienced publishers, who will conduct them with efficiency and promptness. The editorial charge continues in the hands of Dr. Nichols, who will be assisted by Wm. J. Rolfe, A. M., of Cambridge, one of the authors of those excellent treatises upon Chemistry, Natural Philosophy, Astronomy, etc., known collectively as the "Cambridge Course of Physics." Mr. Rolfe is a thorough scholar and an accomplished writer, and will add greatly to the interest and usefulness of the JOURNAL.

It will be observed that we make no change in the general tone and aims of the paper. Its success is due to its open, frank, fearless discussion of all scientific and collateral subjects, and to the brief, plain, practical character of its teachings. It will continue in the future as it has been in the past. The increased space so long needed, which is now at our disposal, will enable us to give more attention to the departments of Agriculture and Horticulture, in their relations to chemistry and the allied sciences. It is well known to our readers, that the editor during the past seven years has been engaged in a course of scientific experiments in husbandry at " Lakeside Farm," in Essex county, thirty miles from the city. The time has arrived when results may be fairly considered, and they will be presented in our columns from month to month, with the hope that some new and useful ideas may be imparted, and the great interests of Agriculture thereby promoted. The claims of our medical readers must not be overlooked. We doubt if any strictly medical, or other publication, in the country has so large a patronage from this class as our own has. It is safe to say that *one sixth* of all the physicians in active practice in the United States, are readers of the JOURNAL. It is not alone for any medical news or information imparted, that we receive this large support from physicians, but because we treat upon subjects of great interest to cultivated men of every profession. Physicians wish to know what is transpiring in the world of science and art, outside of their special vocation, and it is a relief for them to turn from the study of "cases," and the care of the sick and suffering, to the consideration of matters relating to agriculture, inventions, art processes, and the problems and discoveries which are connected with the *Science of Home Life.* More space will however be devoted to Medical Chemistry and Pharmacy, and all that is new in these departments will be promptly noticed.

Although ours is a *chemical* journal, we have not hesitated to discuss topics properly belonging to the several departments of physical and natural science. Interesting facts, and new discoveries in Astronomy, Optics, Natural History, Mechanics, etc., will continue to receive attention in our columns, so far as our limits will permit. The JOURNAL, while maintaining the accuracy and upholding the dignity of true science in every department, will strive to present topics which are designed for general reading, in a familiar way, so as to be readily understood by every one. Some of the most distinguished scientific gentlemen in the country have promised to aid us, and we hope to make the JOURNAL a welcome visitor in every family to which it gains access.

THE "WATER GAS" PLAGUE.

OUR friends in the Southern and Southwestern States have been sadly afflicted during the past six months, with an epidemic, which may properly be called the "water gas plague." Those sections have suffered severely, because so few of the people have had the affection, or found exemption from it through "vaccination." In this city, and in New York, many of the capitalists and "easy dupes" have had the "plague," and its effects have been truly dreadful. A large number of cases proved fatal, and those patients who recovered are so "poor" that their friends scarcely know them. The water gas plague is carried from city to city, and from town to town, by vicious men who make a business of spreading the infection. The Southern gentlemen have "caught it" from two or three "peddlers" from the North, with "carpet bags" filled with "recommendations," "deeds," "rights," etc. One scamp from this section appears to have infected large numbers, who are now very indignant concerning his transactions, and for a remedy are sending "cases" to lawyers in this city. The best remedy, or rather a certain *prophylactic* (a doctor's word meaning a preventive remedy), is the BOSTON JOURNAL OF CHEMISTRY. No one who patronises the JOURNAL will be likely to suffer from the "plague." It exposes the "water gas" and other humbugs so often and so thoroughly, that peddlers of these commodities find it difficult to enter dwellings or workshops to infect the inmates. If by any means admission is gained, they are "kicked out" promptly and without ceremony. We would again state to our readers that all inventions and devices, by which it is claimed that water or steam is decomposed and burned, have no practical or money value. Chemical art and discovery have thus far failed to produce any machine or device, by which this end is reached. Beware of all charlatans, who offer for sale "water gas" machines, "water gas," "liquid gas," or any thing of the kind. They are all worthless.

A NEW THEORY OF ANIMAL HEAT.

THE following extract from the *New Jerusalem Messenger* has been sent us by a correspondent: —

"A learned Yale College Professor lectured in the hall of the Cooper Union lately, before the American Institute. His subject was the 'Correlation of Physical and Vital Forces,' and in the course of his remarks he ventured upon this statement: —

'The heat which is produced by the living body is obviously of the same nature as heat from any other source; it is recognized by the same tests; it may be applied for the same purposes. As to its origin, it is evident that since potential energy exists in the food which enters the body, and is there converted into force, a portion of it may become the actual energy of heat. And since, too, the heat produced in the body is precisely such as would be set free by the combustion of this food outside of it, it is fair to assume that it thus originates. To this may be added the chemical argument that while food capable of yielding heat by combustion is taken into the body, its constituents are completely, or almost completely, oxidized before leaving it; and since oxidation always evolves heat, the heat of the body must have its origin in the oxidation of the food.'

"This assertion he supports by another, namely, that the carbon and hydrogen contained in the food daily consumed by a human being would, if burned out of the body, produce the same or a greater quantity of heat as that given out by the body which consumes them. This is a specimen of that kind of reasoning which deservedly brings scientific men into contempt with the public. Undoubtedly, food taken into the system is oxidized; but to say that vital heat originates in this oxidation is as absurd as to say that love does. When a man gets angry or excited, and his blood boils, his face flushes, and his whole frame is on fire, as we say, is that phenomenon the result of the oxidation of carbon? Is it not rather the result of spiritual forces acting in and through the body, and only incidentally consuming the carbon and hydrogen contained in it?"

In our last number, we alluded to the "scientific" lucubrations of a Western Doctor of Di-

vinity in a religious newspaper, but they are thrown quite into the shade by the above, which, in fact, outdoes anything that we have met with in the same line — with possibly one exception, to be mentioned before we get through.

"Undoubtedly food is oxidized," but it is absurd to say that "vital heat originates in the oxidation," although, as the lecturer had stated, and as every schoolboy knows, "oxidation *always* evolves heat." Does our clerical friend mean to say that this heat is lost or wasted in some mysterious way, and that the heat which manifests itself is generated in its stead "by spiritual forces?" If so, it is a very striking illustration of the simplicity and economy of the Divine methods of working.

Does the writer really not know the difference between a fact and a metaphor? When "the blood boils" and "the whole frame is on fire," is the figurative "heat" at all like the vital heat, which he treats as a similar "phenomenon?" When a man gets angry, spiritual forces are undoubtedly acting through his body; but that there should be in *that* case an "incidental" consumption of carbon and hydrogen, appears to us quite as "absurd" as that animal heat should be directly produced by burning the same substances.

We intimated above that we had met with *one* thing in print which is richer in its way than the extract from the *New Jerusalem Messenger*. It is the following, which actually appears as an advertisement in an English paper: —

"British science having been for some time suspected of owing much of its reputation to the indifference of the general public on philosophical subjects, the truth or accuracy of which it has had no special means of acquiring practical information, or has been more or less blinded by an overweening confidence in the supposed skill of paid officials or royal professors, several gentlemen have made it their business, at a great cost of time and labor, to investigate the grounds on which the various Astronomical and Geographical Societies have based many of their principal theories. The *assumed* convexity or curvature of the earth's surface is found to be as gross a delusion as its supposed orbital and axial motion — that it is nothing but a stationary plane of hill and dale and level, over the face of which the sun and moon and stars revolve; that Ptolemy and the ancient Greek philosophers were the only truthful and trustworthy authorities on matters of astronomical science, and that the later theories of Galileo and Sir Isaac Newton are directly contrary to Scripture, to reason, and to the positive evidence of our senses. Those who require or are disposed to accept further particulars, are requested to communicate with ——, enclosing three stamps, for pamphlets and postage; with lists of larger works on this subject. Literary and Philosophical Societies will do well to disabuse their minds of the impression that they can much longer resist and resent the growing demand for a thorough revision and reconstruction of their antiquated and erroneous systems."

Thanks to Editors and Publishers. — We are under great obligations to the medical, agricultural, scientific, and secular press throughout the country, for the many kind and complimentary notices which they have given the Journal during the past four years. Inasmuch as these commendations have been unbought and unsolicited, they have afforded us much gratification. We shall endeavor, so far as we can, when opportunity offers, to make some return for these acts of kindness. The publishers and editors who have sent us, in the way of exchange, their able and expensive journals, have received but a poor return for what they have given. There has appeared to us such manifest injustice in an exchange upon even terms with most journals, that we have not, we think, in a single instance solicited it. The press — secular, scientific, agricultural, etc. — in every section, have been pleased to copy from us frequently and liberally, and full credit has been given in most cases. We hope conductors of journals will continue to find in our columns matter worthy of being presented to their readers.

EDITORIAL NOTES.

Valuable Information. — The following is among the "Answers to Correspondents" in a New York city paper (*not* "Punchinello") of a few weeks ago: "Nelson. — It is said that the human hair is vegetable. It certainly assumes the appearance of an animal when it turns to a snake, or something that looks and acts serpentine." We trust that "Nelson" will continue to draw from this fount of scientific wisdom, and that the other readers of the paper may still be so fortunate as to get a share of what "slops over."

A scientific exchange states that a solution of carbonate of ammonia will restore spots discolored by acids, "and indeed *all* spots, *whether produced by acids or alkalies*." We hardly need say that this method of restoring the color will fail in all cases where the spot is caused by alkalies, and in some instances where it has been produced by mineral acids, — nitric, for instance.

Another journal, usually very careful in its statements on scientific matters, informs its readers that a pitcher of water, if kept in a sleeping-room, will absorb *all* the noxious products of respiration, but the water itself will become unfit for use. One would infer from the paragraph (which we have mislaid, or we would give it in full) that a pitcher of water in a close room is a sufficient substitute for ventilation. Of course, neither a pitcher nor a tub of water would answer any such purpose.

Does Light put out Fire? — There is a popular notion that it does, but, like many such notions, it is a mere superstition. Prof. Tomlinson recently made a series of experiments upon candles of different sizes and weights, in dark chambers and in daylight and sunlight. He found that the increase of temperature led to increase of consumption of material, and *vice versa*; and "the whole result may be stated that, in any case, the difference is so small that it may be referred to accidental circumstances, such as temperature and material; the final conclusion being that the direct light of the sun, or the diffused light of day, has no action on the rate of burning, or in retarding the combustion of an ordinary candle." Several years ago, Prof. Horsford, and other experimenters in this country, obtained similar results.

Another old Superstition spoiled. — The popular belief that the eye of a dead animal bears the impress of the last object upon which it looked in life, has been investigated in cold blood by scientific men in Germany. Thirty animals were killed and examined by the philosophers, and the result was as fatal to the superstition as it was to them. In no case was there the slightest evidence in its favor.

An Old Lady. — There is a woman living in Virginia who is said to be 115 years old. She is the widow of a Revolutionary soldier, and enjoys good health, though her hearing is quite gone and her sight somewhat impaired. Her mental faculties are unaffected by age. We regret to add that the old lady both chews and smokes tobacco. Some benevolent person should send her one of the "anti-tobacco tracts," in which the danger of shortening one's years by the use of the weed is duly set forth. Her address, as given in one of the medical journals, is Mrs. Chloe Flatford, Dumfries, Prince William County, Va.

Singular Coincidence. — Arthur's *Home Magazine* for June has an article on "Women as Chemists," which happens to be the same, word for word, as one which appeared with that title in the Journal for April. If it were not given as original in the Philadelphia monthly, we should really believe that we wrote it. As it is, we cannot help referring to it as a remarkable coincidence.

A Popular Cyclopædia. — A good cyclopædia is a library in itself. It gives many volumes in a few, and their contents are not only condensed but classified for ready reference. If one cannot afford to buy the larger cyclopædias in ten or twenty volumes, *Zell's Popular Cyclopædia*, now publishing in numbers and to be completed this year, is a cheap and really serviceable substitute. Into two goodly quartos it will compress an epitome of the whole world of human knowledge. The editorial work is ably done, and the illustrations and the general mechanical execution are much to the credit of the publisher.

LITERARY NOTES.

Of our foreign exchanges there is none that we value more highly than *Nature*, the weekly illustrated journal of science published by Macmillan & Co. London. We are glad to know that its first half year has proved "an emphatic success," and that it begins its second volume with the prospect of rapidly increasing popularity and usefulness. It ought to have a large sale in this country. By special arrangement with the publishers (through their branch house in New York) we can furnish any person, who is not already a subscriber to *Nature*, with that periodical *and the* Journal for $5.00 per annum, which is the regular price of the former alone for American subscribers.

Scientific Opinion is another English journal whic we read with great interest. It is just what it clain to be — "a weekly record of scientific progress : home and abroad." Every number contains one more illustrated articles. The address of the pu lishers is 74 *Great Queen St., London, W. C.*

The Popular Science Review is a quarterly mag zine, published by Robert Hardwicke, 192 *Piccadil London, W.* Each number has several long pape on scientific topics of popular interest, from some the ablest writers in Great Britain, together with carefully compiled summary of intelligence in t various departments of science, etc.

Science Gossip is an entertaining monthly fro the same publisher. It is mainly devoted to bota and zoölogy, and is copiously illustrated.

Several valuable reports, by Prof. C. F. Chandl the Chemist of the Metropolitan Board of Healt New York, have been published in neat pamph form by the Appletons. The one upon the "G Nuisance in New York" is a detailed history of two years' fight between the Board of Health an gas company that persisted in making its purificati process a nuisance to a large portion of the ci Incidentally, the various methods of purifying g are described in detail, and their comparative mer thoroughly discussed. The reports on "the qual of the milk supply," upon "the water supply," a upon "kerosene oil," are briefer but not less valual in their way.

Mr. Jas. Campbell, 18 Tremont St., has publish Volume I. of *The Journal of the Gynæcological*

ciety of Boston, including the numbers from July to December, 1869. The book of four hundred pages, with its excellent typography and tasteful binding, will make a handsome, no less than a useful addition to the physician's library. The second volume will soon be ready in the same style.

The Chemical History of the Six Days of Creation, by Prof. John Phin, offers a new solution of an old problem — the reconciliation of the Mosaic cosmogony with modern science. The author does not assume "that we have reached the ultimate results either of scientific research or of biblical exegesis," but he believes that the biblical record, as interpreted by the best scholarship of the day, is in perfect harmony with the most recent developments of science. The book cannot fail to interest even those who do not fully accept the theory it advocates.

Messrs. Hurd and Houghton have published *The Nation*, by E. Mulford, a profound philosophical disquisition upon "the foundations of civil order and political life in the United States." Somebody has remarked, that, though we are a nation of politicians, we have produced no important work on political science, with the single exception of "The Federalist." This book of Mr. Mulford's must be counted as a second exception, if we endorse the verdict of our ablest critics. It is a work to be studied, and one that will richly repay study. The publishers have given it a dress in keeping with its standard character.

Messrs. Scribner & Co., have issued the third volume of their edition of *Mommsen's History of Rome*, which we have already commended, and have reduced the price to $2.00 a volume. The latest addition to their "Library of Wonders" is *The Wonders of Architecture*, and it is one of the best of the series. A careful revision of the translation would improve it here and there, though it is quite up to the average of English work in that line. We note a few errors of the type, as "the cathedral of *Bruges*" where that of *Bourges* must be meant, etc. Messrs. Nichols and Hall have all these books of Scribner's at their new quarters, 32 Bromfield Street.

To our Medical Exchanges. — In order that the thousands of physicians who take the Journal may know what is to be found in the professional journals of the day, we purpose giving regularly a list of the more important articles in our medical exchanges. Our limits will not permit us to give their "contents" in full, but we hope to be able to call attention to whatever is most valuable in each number. It is desirable, of course, that we should receive the periodicals regularly, and as promptly as possible.

☞ We would suggest to our friends that they preserve the numbers of the Journal for binding. We have put the advertising pages outside the reading, that they may serve as a cover for the protection of the latter until the volume is complete. In binding they can be left out (it will be noticed that they are paged separately), and you then have a volume of solid reading, fully equivalent to an ordinary octavo of four hundred pages. Even with the cost of a good binding added, it will be a very cheap book for the household library. We intend to publish a title page and index for the volume at the end of the year, and to make arrangements for binding it at reasonable rates.

☞ One of the most delightful popular lectures upon science which we have attended for a long time was delivered by Prof. Gray of Cambridge, at Haverhill, Mass., a short time since. His subject was the "Fertilization of Flowers by Insects," and the plain, practical, instructive way it was presented left a pleasing impression upon the mind of every listener. Like Tyndall in England, our distinguished botanist is willing to draw from the rich storehouse of his mind important facts, for the elevation and improvement of the masses.

☞ We have found Mr. Bernard Quaritch, 15 Piccadilly, London, to be a most efficient and faithful Agent for selecting and purchasing foreign books. He has executed many orders for us very satisfactorily, and we commend him to those of our readers who wish to pick up books in the London market.

☞ We are pleased to notice that Dr. Packard's *Guide to the Study of Insects* is receiving the commendations of the scientific press, and of distinguished naturalists in Europe. The *Popular Science Review*, *Nature*, *Scientific Opinion*, etc., bestow upon it high praise. It is, indeed, a work of which we have reason to be proud. Dr. Packard is connected with the Peabody Academy of Science, at Salem, Mass., and the book is published at the "Naturalist's Book Agency" in that city.

ATOMS.

A telegram was lately sent from London to Teheran in Persia, 3,700 miles, and an answer received, in thirty seconds. — Out of 120 students in the Michigan Agricultural College, 8 are young women. — In Pennsylvania a sheet of iron has been rolled, three feet long and a foot wide, weighing but three ounces. It is thinner than common writing-paper. — A Yankee paper-mill has made a sheet of paper 25 *miles* long, 46 inches wide, and weighing about 5 tons. — To write on a photograph, use a solution of one part of iodide of potassium in two parts of water, with a steel pen. It will make white letters on the dark ground. — Collodion is recommended as a varnish to stop up the pores in the shell, and thus prevent eggs from decaying. — England spends a hundred millions of dollars annually for beer. — The *Gas Light Journal* thinks that magnesium will soon be sold at a shilling (24 cents) an ounce retail. — The richest gold mine in California yielded last year a profit of $340,000. — Cornell University is going to send a scientific expedition to Brazil. — After a trial of a year and a half, and the eating of two hundred and fifty horses, it has been decided in Prussia that horseflesh is wholesome. — Another asteroid, the 110th of its class, has been discovered by M. Borelli, at Marseilles, and it is proposed to christen it *Lydia*. — The Pennsylvania pedagogue who is ninety-six years old deserves to be ranked among the "old masters." — A German professor finds that, if you take out a frog's brain, and then rub a wet finger down his back, he will croak as if pleased. Frogs must be very easily pleased. — The illuminating power of coal-gas is increased by heating it, and diminished by cooling it. A given quantity produces more light in a single burner than in several. — When Adam and Eve ate of the tree of knowledge, did they take the "higher branches?" — Though it is said that the lower animals have not the vices of man, there is no doubt that some insects are backbiters and that most quadrupeds are tale-bearers. — Do not have your water-pails painted inside; and for the outside a coat of varnish is better than paint. — Over *twelve millions* of eggs were carried in a single train on a Western railroad the other day. What a mess it would have made if that train had smashed up! — Switzerland, though noted for its manufactures and its inventions, has no patent laws. — A great Polar expedition for 1871 and 1872 is preparing in Sweden. Somebody has lately suggested that the Pole be *removed* by the first expedition that reaches it, so that people may not be tempted to go in search of it any more. — Speaking of the Pole reminds us that out in Minnesota they have "raised" ice thirty-three inches thick, and so transparent that you can read a newspaper through it. — Philadelphia has 179 miles of street railways. — Railways of two or three feet gauge are gaining favor in Great Britain. — In South America they are carrying telegraph lines across from Chili to Buenos Ayres, and by cable to Montevideo, whence another land line is to extend to Rio Janeiro. — A message was lately sent, as an experiment, from New Orleans round through the Atlantic and Western States to its starting-point, in about three quarters of a second. It passed over 4,800 miles of wire, through eighteen States, and through nine "repeaters." — £200,000, or about a million of dollars, was received at the London Custom House as duty on tea in a single week not long ago. — "Sweet and low, sweet and low!" is a line of Tennyson's which *Punch* thinks may be an appropriate quotation on account of the fall in the price of sugar, due to a reduction of the duties. — It is proposed to try the experiment of introducing certain Indian palms — as the date, sugar, and cocoanut palms — into the Southern States. — Counterfeit fruit jellies are made by flavoring gelatine with the appropriate essences. They liquefy with a moderate heat, and may thus be detected.

ANSWERS TO CORRESPONDENTS.

☞ Questions pertaining to *all departments of the paper* — home science, arts, agriculture, medicine, etc., — will be answered under this head, but *only when the subject is one of general interest to our readers.*

Cement for Aquarium. — "D. M. S." asks for a cement "containing no lime or lead, as these substances kill the fish." We can assure him that the cement described in our May number (page 124), although it contains litharge, is not liable to this objection. We cannot say as much for the recipe published in April, though that had been commended by excellent authority.

"Sun-Dogs." — A friend out West wants to know what these atmospheric phenomena are. We will premise that they do *not* belong to the same zoölogical species as those stellar quadrupeds known as *Canis Major* and *Canis Minor*, and that they have nothing to do with the dog-days. They are otherwise known as *parhelia*, (the singular of which is *parhelion*) or *mock-suns*. They appear at the points where the circles of solar *halos* intersect, and are due to the concentration of the light at those points. These halos are formed by the refraction and reflection of the sunlight, caused by minute snow-crystals high up in the air. The variety of cloud known as *cirrus*, or *curl-cloud*, is probably composed of these delicate crystals of ice or snow. *Halos*, properly so called, are of comparatively rare occurrence, and should not be confounded with the "rings round the sun," which may be seen whenever a light fleecy cloud comes between us and the sun. The latter are known to meteorologists as *coronas*, and never show the *intersecting* circles which are usually seen in the former. They differ also in other respects which it is hardly worth while to enumerate here.

The Upas Tree. — We have received two letters inquiring whether the familiar account of the Upas tree (or "the *Utopia* tree," as we once heard it called in a sermon from a city pulpit) is true or not. The story is a mere fable, which first gained credence in Europe through the narrative of Foersch, a surgeon in the Dutch East India Company's service, published about the middle of the last century. He described the tree as poisoning the air of the whole valley where it grew, so that neither animal nor vegetable could live there. But when Deschamps and Leschenault visited Java, they found that this deadly tree flourished only where vegeta-

tion was most luxuriant, and that it was haunted by birds and insects. In another part of Java, there is a narrow valley, where neither animal nor vegetable life can exist, but this is owing to the exhalation of carbonic acid gas from an old volcanic crater. *Upas* is a Malay word meaning *poison*, and is applied to a variety of vegetable products. The proper name of the so-called Upas tree is the *antjar* or *antiar* (the *Antiaris toxicaria* of Leschenault) which grows in many parts of the Sunda and Philippine Islands. It is a very beautiful tree, and sometimes grows to the height of a hundred feet. From its milky juice, mixed with black pepper and the juices of certain roots, the Malays prepare a poison for their arrows which is very prompt and virulent in its action. Cloth is sometimes made from the fibrous bark of the *antjar*, but unless the fibre has been thoroughly cleansed, it produces a painful itching when worn next to the skin.

Since writing the above we have met with an account of this tree in Pouchet's *Universe*. He states that the juice is not poisonous unless introduced beneath the skin. While Leschenault was examining one of these trees which he had cut down, the exudation from the broken branches flowed over his face and his hands, but without injuring him. But eight drops of the juice, injected into the veins of a horse, killed it directly, and criminals have been known to die in five or six minutes after being pricked in the breast with a lancet dipped in the juice.

Medicine.

CHLORAL HYDRATE NOSTRUMS.

THE great success and the growing popularity of that valuable remedy, hydrate of chloral, have led to the putting up for sale of nostrums called "Syrup of Hydrate of Chloral," "True Chloral Anodyne," "Elixir of Chloral," "Solution of Chloral Hydrate," etc. Now it is important that physicians, and all others interested, should understand that the new agent cannot be mixed with syrup, or other aqueous or spirituous bodies, without soon undergoing spontaneous change which renders it comparatively worthless as a hypnotic. What the nature of this change is, we do not well understand at present. We have specimens of the aqueous solution and syrup prepared two months ago, which have undergone important modifications. In crystalline form, in well-stopped vials, the substance keeps perfectly well, and in this form it is probably permanent. If the nostrums just mentioned contain any of the agent, they are worthless, and may be dangerous.

Physicians should prescribe only the crystals, and should be very certain *that they are pure.* The taste of hydrate of chloral is quite unpleasant, but orange juice completely covers it, and so does peppermint water, or essence of peppermint. If taken in aqueous solution, let the patient be directed to suck the juice of an orange immediately after swallowing the dose, or mix with the solution a little peppermint water, with syrup of tolu. The following is a good formula:

℞	Chloral hydrate,	ʒi.
	Aq. menth. pip.,	℥ss.
	Syrup tolu,	℥ss.
	Aqua,	℥ij.

Dose, from one half ounce to two ounces, as may be required.

The mixture should not be prepared in large quantities, nor be kept for any length of time, for the reasons intimated above.

COD LIVER OIL.

THERE are fashions in medicine as in other human affairs. Some one boldly asserts the efficacy or superiority of a new-fangled medicament, and straightway the "hoi polloi" of the profession prescribe the novelty, or adopt the mode of treatment recommended on no better grounds than Dr. Somebody's *ipse dixit.* Cod liver oil is just now a bright particular example of this sheep-like propensity to follow the bell-wether, whithersoever he may lead. Here have we benighted New York practitioners been prescribing, year after year, oils made by our native manufacturers with such thoroughly satisfactory results, that in the words of an authority than whom there is none higher among us, "I (we) desire no better." Yet we are asked to believe our experience false, and that such oils had, after fair trial, proved worthless as medicines. Moreover, we are told that they are made by a disgusting process, — minutely described before a learned body, — a process which, though applicable, perhaps, to the production of the worst article that could be used in the composition of tanner's "dubbing," it is safe to say never was used in the manufacture of salable medicinal oil. But perhaps this description was only intended as a humorous "suggestio falsi," a sort of preface to the elaborate puff of the oil made by one Möller, a Norwegian, manufactured by an original and elegant process — also elaborately described, and declared to be the only oil fit to be prescribed for internal use.

Somewhat startled by such "bluff" assertions, we took the trouble to inquire for ourselves, and discovered that the best American oils are made by a process the same in all essential particulars as that of Möller, minor differences being in favor of Yankee ingenuity. Moreover, according to the official report on the International Exposition of fish products and apparatus connected therewith, held at Bergen, Norway, in 1865, and now before us, Möller's oil was so inferior to that of other manufacturers, that while five of those received medals, and twelve honorable mention, the committee, in awarding him a medal for *the pains he had taken to improve the manufacture*, let him down gently on the subject of *his* oil, by remarking that probably the medallists had taken advantage of Möller's labors, and further improved upon his processes. None of these superior oils, however, have appeared in this country, and one would be almost justified in suspecting that, having ceased to be so much in demand in Europe, Möller's oil is now to be forced on the American market. Such things have happened before, and history — even of drugs — repeats itself.

A comparison of Möller's oil with the best samples of American manufacture, is rather against than in favor of it. It is very bright, but not so "sweet" — so free from all objectionable fish odor and taste, as that made by our first-class houses. When we add that it is sold at nearly double the price of the actually superior native article, we think it scarcely needful to suggest that it is not quite fair to the patient, to make him play the unpatriotic part of purchasing an inferior foreign article at a high price, while a much smaller outlay will command an every way more desirable product of home industry. — *N. Y. Medical Gazette.*

Remarks. We are pleased that so discriminating and sensible a journal as the *N. Y. Gazette* should call attention to the bad character of the foreign cod liver oils. They are usually of a dark brown or reddish color, and of a disgusting odor. As a class, they are filthy and impure, and unfit for medicinal use. Pure, fresh cod liver oil, properly prepared, cannot be of a *brown* color. If it possess that tint, it shows that it has been injured in the process of extraction, or that it is made up of a mixture of various kinds of oils. It is impossible to procure better oil than is produced on the coast of New England, from Cape Cod to Machias in Maine. This is of a light straw color, very limpid and sweet, and not of an unpleasant odor. The process of extracting and clarifying the oil is very simple. The fresh livers are placed in a jacketed pan heated by steam, and when the oil is separated from the "scraps," it is passed through felt bags until it is perfectly nice and clear. To remove a portion of the stearine, it is subjected to refrigerating mixtures in the summer, and the uncongealable portion is drawn off and placed in bottles. This is the oil which affords the best results when used as a medicine, and if patients do not "cry for it," they do not find it impossible to swallow it.

MEDICAL MEMORANDA.

DEATH BY THE GUILLOTINE. — Dumas, in one of his novels, makes the head of a guillotined man, two hours after the operation, not only call out the name of a lover, but actually recognize him by dim candle-light through a sack, while tears of sorrow at the same time drop from its eyes. Novelists not being bound to scientific accuracy in these matters, nobody thought much of this rather astounding "case;" but when, the other day, a French medical man, Pinel by name, asserted that the guillotine was one of the most horrible modes of execution, since the head remained alive for at least three hours afterwards, the matter at once attracted a good deal of attention. It appears, however, that Pinel has been quite as much "indebted to his imagination for his facts" as Dumas was. In a recent communication to the *Society of Legal Medicine*, Doctors Evrard and Beaumetz describe a series of experiments made by them upon a head which was delivered to them five minutes after decapitation. The decision to which they come, is the same as that of the Medical Association of Mayence, in 1803, after a series of similar experiments — namely, that "the sensation of external impression does not persist for an instant after decapitation." The reputation of the guillotine is therefore happily vindicated. It does its work promptly in every sense, and would appear, on the whole, to have some advantages over the gallows.

A QUEER CASE OF POISONING. — War against dogs having been duly declared in Chicago, the policemen were supplied with little pellets of raw beef, with a few grains of *strychnia* enclosed in each. These, in the slang dialect of the police, came to be known as "lunch." A new member of the force, probably from the rural districts, took this term in its literal sense, and waxing hungry in the course of his nocturnal rounds, refreshed himself with several of the official pellets. Feeling symptoms of colic soon after, he resorted to the standard prescription of brandy and peppermint, but as it "instantly didn't do no good," he called in the doctor, who pronounced the disease "apoplexy of the bowels." Fortunately, however, the patient happened to remark that he "felt bully before eating that lunch." This led to an inquiry into the nature of the lunch and a better understanding of the case, and the man is now likely to recover.

APPLES VERSUS DYSPEPSIA. — An eminent French physician ascribes the decrease of dyspepsia and bilious disorders in Paris to the greater

consumption of apples, which he deems an admirable prophylactic and tonic, as well as a very nutritious and easily digested article of food. It is estimated that the Parisians devour one hundred millions of apples every winter.

ELECTRICITY IN THROAT DIFFICULTIES. — Dr. Poggioli, the official physician of the Italian Music Academy, of Paris, has been very successful in the application of electricity to several cases of sore throat and hoarseness among the pupils of the Imperial Conservatory of Music. The pupils thus cured belonged to the class of Delle Sedie, who was much struck by the wonderful results obtained by Dr. Poggioli's new method for the treatment of the voice.

The celebrated Professor, having to appear, a few days afterwards, in "Rigoletto," at a very short notice, and being at the time exceedingly hoarse, sent for Dr. Poggioli, who applied electricity and cured the hoarseness, which otherwise would have prevented Delle Sedie from taking the difficult part he had to perform; the cure was indeed so complete that the great artist sung that evening better than ever, and was throughout enthusiastically encored.

SULPHATE OF IRON IN SUPPURATION. — A child burned all over the body was recently brought to the Children's Hospital of Lausanne. The suppuration from his wounds was so abundant that the ward in which he was lodged became absolutely uninhabitable. M. Joel then placed him in a bath containing two handfuls of sulphate of iron. The cessation of pain was almost immediate; after repeating this bath twice a day, for fifteen or twenty minutes at a time, the suppuration moderated, the fetid odor disappeared, and the little sufferer recovered rapidly.

OSCAR LIEBREICH. — This physician, whose researches concerning chloral hydrate have made him so suddenly famous, is chemical assistant in the Pathological Institute at Berlin.

ETHER INTOXICATION. — We referred in our last number to the prevalent use of ether for purposes of inebriation in certain counties of Ireland. A writer in the Dublin *Medical Press* says that "there is a widely diffused popular impression that ether is used as a stimulant by women of the higher ranks of society." The same writer believes that, in the Irish district just mentioned, the practice is not due to the desire of "getting drunk more cheaply," but to "the laudable efforts made by the Roman Catholic clergy in inducing their flocks to abstain from whiskey. The consumers of ether are said to be nearly all Catholics, and to belong chiefly to the class of small farmers, though the habit certainly prevails among mill hands and other operatives."

The writer believes that there is less danger from the habit than from ordinary dram-drinking, for the two reasons that follow: "If we assume that there is nothing specifically injurious in the action of ether, it will readily be admitted that, having a definite chemical composition, and not being very liable to adulteration with other fluids, it must be an improvement upon the sophisticated alcoholic potations, which, with these people, it has replaced. Again, the affinity of ether for water is so slight that dehydration of the mucous tissue of the alimentary canal, and that apeptic action which so well mark the difference between the effect of ardent spirits and of alcohol in the form of unbrandied wine, cannot be evils attending its ingestion."

The extent of the practice may be inferred from the fact that one Dublin manufacturer has supplied to Belfast alone at least 4,000 gallons yearly. Some towns of less than 3,000 inhabitants use from 250 to 300 gallons a year. The fashion to dates back only about five years.

ORGANIC MATTER IN THE BREATH. — From the account of his experiments in this direction, read by Dr. Ransome to the Literary and Philosophical Society of Manchester a short time ago, we gather the following: The total quantity of organic matter passing out of the lungs in the space of twenty-four hours, the subject being in a state of health, is about three grains. In disease the organic matter varies considerably; in health it is tolerably constant in quantity. On the other hand, the free ammonia in the breath is very variable even in healthy subjects. One of the most interesting results given by Dr. Ransome is the fact that a large quantity of organic nitrogenous matter is thrown off by the lungs in kidney diseases, especially in Bright's disease. A deficiency of organic matter was observed in cases of catarrh, measles, and diphtheria.

SOUTH AMERICAN SURGERY. — Our readers doubtless remember the story of the decapitated Brazilian, who, through a slight inadvertence on the part of the operator, had the wrong head fastened on his neck, but nevertheless did "as well as could be expected," — or rather a good deal better. We think that the Argentine Janus, of whom the following "authentic" account is given by a city paper, must be at least a second cousin of the wrong-headed Brazilian: —

"The following extraordinary narrative comes to Chili from San Juan, Argentine Republic: There existed in San Juan an individual eighteen years of age, who had two heads, both of them provided with a countenance at once expressive and of regular outline, each looking toward the sides of the owner, and being united by the posterior part of the cranium. One of the scientific European commissioners, at present travelling through the Argentine Republic, proposed to operate upon the individual, taking away one of the heads. The proposal was accepted, and the operation successfully performed on the 13th ult., without causing the least pain to the patient, notwithstanding that chloroform was not administered, and the operation lasted six minutes. The operation, and the subsequent cure of the parts, is represented as being something marvellous. The head has been preserved in spirits, and will shortly be exhibited in this country."

CHIT-CHAT.

A MAN condemned to death, in England, has had his sentence commuted, because, as the *British Medical Gazette* expresses it, "any attempt to carry out the sentence would have been attended with great risk." As this mode of punishment is usually attended with considerable "risk," this seems at first very much like a joke. The fact was, that, owing to the cicatrization of a severe burn in his childhood, the man's chin had been drawn down towards his chest, and the integuments of his neck so thickened that it would be difficult to adjust the rope in such a manner as to sustain his weight. As the English law knows no other method of execution but hanging, this lucky deformity of the man's neck proved the means of saving his neck. He may well congratulate himself that he was born a Briton and not a Frenchman. The "operation" by the guillotine would have been attended with no "risk."

According to Dr. Lisle, arsenious acid is likely to prove a great boon to those afflicted with mental derangement. He asserts that its administration, even in apparently hopeless cases, restores about two thirds of the patients to health.

It is an old joke that certain people get their living by *dyeing*, but a Yankee swindler has found out how to do the same thing without an apprenticeship at a dye-house. He takes a room at a hotel, and after a brief sojourn tells a sad story of sudden and unexpected loss of lucre. In his despair he shuts himself up, swallows a white powder, and sets up a groaning which draws a sympathetic throng of fellow-boarders to the spot. The doctor is called in, with stomach-pump and other appliances, and the life of the unhappy man is saved. A purse is of course raised for him, and he soon goes his way to some other city, where the loss, despair, and attempt at suicide are reënacted. His life is saved every time, and the fellow really makes a very good thing out of it.

A late number of the *Moniteur Scientifique* refers to a "liquid iron soap" used as a liniment for burns. It is prepared by heating on a water-bath oleic acid, and gradually adding freshly precipitated peroxide of iron, which readily dissolves. The mixture should be continually stirred. Oleates of other metallic oxides may be obtained in a similar way.

There is much complaint in Paris of the inferior quality of the opium in the market. None can be found that yields more than 5 or 6 per cent of morphia, while the price is 100 francs ($20 gold) a kilogramme (2.2 lbs.) But chloral is the popular sedative of the day, and its use is rapidly increasing. The "hydrated chloral capsules" of Limousin promise to be a favorite form for the administration of the medicine. As we remarked in our last number, Parisians cannot tolerate any physic that is "bad to take."

Figaro tells the following story: Macready, the great actor, wrote almost illegibly, and a box-order which he had given to a friend was sent, for the fun of the thing, to a druggist's as a physician's prescription. The assistant, after mixing some of the ingredients, was posed by the chirography, and took the paper to his master, who readily completed the mixture, and handed it to the customer with the remark that it was an admirable thing for a cough — price, two francs. Of course, the story is a mere joke; but it is a fact that an English physician in Paris, on a Christmas day, wrote a prescription for a plum pudding, with directions to the druggist to send the cataplasm while hot.

A compound isomeric with chloral has just been discovered by two Berlin chemists. It differs from ordinary chloral by having a much higher boiling-point.

TREATMENT OF RHEUMATIC FEVER BY PERCHLORIDE OF IRON.

J. Russell Reynolds, M. D., F. R. S., London, called attention to this agent at the last meeting of the British Medical Association. The marked effects of tincture of perchloride of iron in such diseases as erysipelas and diphtheroid sore throat had induced Dr. Reynolds to try it in acute rheumatism — which agreed with the others in coming under the class of "spreading" inflammatory affections. He had given it in eight cases, with such success as would justify a further trial. Having given brief histories of the eight cases, he directed attention to certain points: 1. The relief of the joint-affections was definite, uniform, and speedy. In four cases it was removed in one day; and the longest period of suffering after the commencement of the treatment was five days. 2. Excluding one fatal case with cerebral symptoms, and another where there was intercurrent pneumonia, the temperature became normal between the second and the seventh days; the mean duration of pyrexia being a little less than five days and a half. 3. Excluding again the two exceptional cases already mentioned, the total duration of rheumatic fever from the outset varied from seven to fifteen days, giving a mean of ten and a half days. 4. The earlier the iron was given, the shorter was the duration of the disease. No headache or other symptom of discomfort was produced by the iron.

Poisonous Hair Dyes and Cosmetics. — We have just received Prof. C. F. Chandler's Report on these and kindred nostrums, to the Board of Health of New York City. Of sixteen preparations for the hair which he analyzed, *fifteen contained lead* in the varying proportions shown in the following table: —

Grains of Lead in one Fluid Ounce.

1. Clark's Distilled Restorative for the Hair	0.11
2. Chevalier's Life for the Hair	1.02
3. Circassian Hair Rejuvenator	2.71
4. Ayer's Hair Vigor	2.89
5. Prof. Wood's Hair Restorative	3.08
6. Dr. J. J. O'Brien's Hair Restorer of America	3.28
7. Gray's Celebrated Hair Restorative	3.39
8. Phalon's Vitalia	4.69
9. Ring's Vegetable Ambrosia	5.09
10. Mrs. S. A. Allen's World's Hair Restorer	5.57
11. L. Knittel's Indian Hair Tonique	6.29
12. Hall's Vegetable Sicilian Hair Renewer	7.13
13. Dr. Tebbett's Physiological Hair Regenerator	7.44
14. Martha Washington Hair Restorative	9.80
15. Singer's Hair Restorative	16.39

For a fuller account of these delectable compounds, as well as of sundry lotions for the skin, "enamels," and kindred cosmetics, see Prof. Chandler's Report, which is given in full in the American Supplement of *The Chemical News* for May, 1870, published by W. A. Townsend and Adams, New York.

Test for Calomel. — Put a little of the suspected calomel on a clean knife-blade, moisten with alcohol, and rub with a cork. Pure calomel does not attack the steel, but corrosive sublimate, or calomel contaminated with the sublimate, produces black spots.

QUITO.

Prof. Orton, in "The Andes and the Amazon" (the best book on that region that has yet appeared), gives the following account of this South American city, which is situated 9,520 feet above the level of the sea, or some 3,000 feet higher than the top of Mt. Washington in New Hampshire: —

"The mean diurnal variation of the barometer is only .084. So regular is the oscillation, as likewise the variation of the magnetic needle, that the hour may be known within fifteen minutes by the barometer or compass. Such is the clock-like order of nature under the Equator, that even the rains, the most irregular of all meteorological phenomena in temperate zones, tell approximately the hour of the day. The winds too have an orderly march, the ebb and flow of an aërial ocean. No wonder watch-tinkers cannot live where all the forces of nature keep time. Nobody talks about the weather; conversation begins with benediction or compliments."

"There are only three small drug-stores in the great city of Quito. The serpent is used as the badge of apothecary art. Physicians have no offices, nor do they, as a general rule, call upon their patients. When an invalid is not able to go to the doctor, he is expected to die. Yellow fever, cholera, and consumption are unknown; while intermittent fevers, dysentery, and liver complaints, so prevalent on the coast, are uncommon.

"The ordinary diseases are catarrhal affections and typhoid fever. Cases of inflammation of the lungs are rare; more coughing may be heard during a Sunday service in a New England meeting-house than in six months in Quito. Asthma is also common in Quito, while phthisis increases as we descend to the sea."

The author considers that the prevalence of typhoid fever is due to filth, want of ventilation, and poor diet.

Of the cinchona-tree, Prof. Orton says: —

"Dr. Weddell enumerates twenty-one species, seven of which are now found in Ecuador, but the only one of value is the C. succirubra (the Calisaya has run out) and this is now nearly extinct, as the trees have been destroyed to obtain the bark. In 1867 only five thousand pounds of bark were exported from Guayaquil. The Indians use the bark of another tree, the Maravillas, which is said to yield a much stronger alkaloid than cinchona."

MEDICINE IN NEW MEXICO.

From an entertaining article on this subject in the first number of the *Indiana Journal of Medicine*, — which, by the way, begins its career in a very promising style, — we make the following extract: —

"According to the popular belief most articles of diet or of medicine, or that may, under any circumstances, be taken into the stomach, are divided into two classes; those which contain heat and those which contain cold. At the same time the human body is supposed to be capable of storing up an indefinite quantity of these two principles, either of which, in excess, gives rise to disease. Accordingly, the science of medicine is narrowed down to determining under what conditions there is an excess of one or the other, and giving the antidote in the form of some substance containing a large proportion of the opposite principle.

"Among the remedies containing *cold* the common black *cricket* is held in high repute. The 'cricket on the hearth' would chirp at his peril in a Mexican house if one of the family chanced to be attack[ed] with fever.

"I once heard a conversation between two Mex[i]cans, which ran about as follows: 'Do you know th[at] Lopez has come down from the mines and is in tow[n] under the doctor's care?' 'No, you don't sa[y] what's the matter?' 'Why, the stupidest thing y[ou] ever heard of. He got sick up in the mines and ha[d] a great deal of heat, and to cure himself he took *t[wo] whole crickets*. It made him so cold that I doubt [if] he ever gets warm again.' 'Is it possible? T[he] stupid fellow! If he had taken one leg it wou[ld] have been well enough, but two whole crickets — what imprudence!'"

SYRUPS FOR SODA AND MINERAL WATE[RS].

Sarsaparilla. — Take of simple syrup, 4 pint[s]; compound syrup of sarsaparilla, 4 fluid ounces; car[a]mel, 1½ fluid ounces; oil of wintergreen and sassafra[s], of each, 6 drops.

Lemon. — Grate off the yellow rind of lemo[ns] and beat it up with a sufficient quantity of gran[u]lated sugar. Express the lemon-juice; add to ea[ch] pint of juice 1 pint of water, and 3½ pounds of gra[n]ulated sugar, including that rubbed up with the rin[d]; warm until the sugar is dissolved, and strain.

Another recipe for lemon syrup is as follows: Dissolve 6 drachms of tartaric acid and 1 ounce [of] gum arabic, in pieces, in one gallon of simple syru[p]; then flavor with 1½ fluid drachm of best oil of lemo[n]. Or flavor with the saturated tincture of the peel [in] cologne spirits.

Orange. — This may be made from the fruit [in] the same way as lemon syrup, or the following fo[r]mula may be used: Dissolve 6 drachms of citric ac[id] in 1 gallon of simple syrup, and add 2 fluid drach[ms] of fresh oil of orange in two ounces of alcohol; or i[n]stead of the alcohol solution of the oil, use the sat[u]rated tincture obtained by macerating the fresh pe[el] for 10 days in sufficient cologne spirits to cover.

The lemon and orange syrups, made from the fru[it], after being strained, may be diluted with an equ[al] bulk of simple syrup. One dozen of the fruit is suf[fi]cient to make 1 gallon of finished syrup.

Ginger. — Mix two fluid ounces of tincture [of] ginger with 4 pints of simple syrup.

Vanilla. — Mix two fluid ounces of extract [of] vanilla with 4 pints simple syrup.

Strawberry, Raspberry, or Pineapple. — Mash the fresh fruit, express the juice, and to ea[ch] quart add 3½ pounds of granulated sugar. The juic[e] heated to 180 degrees Fahrenheit, and strained [or] filtered previous to dissolving the sugar, will ke[ep] for an indefinite time.

Nectar. — Mix 3 parts vanilla syrup with 1 ea[ch] of pine-apple and lemon syrups.

Sherbet. — Mix equal parts of orange, pine-a[p]ple, and vanilla syrups.

Orgeat. — Cream syrup and vanilla syrup, ea[ch] 1 pint; oil of bitter almonds, 4 minims.

Cream. — Take of Borden's condensed milk, [1] pint; water, 1 pint; sugar, 1½ pound. Heat to boi[l]ing, and strain. This will keep for over a week in [a] cool place.

Coffee. — Pure coffee, roasted, half a pound, infused in boiling water, half a gallon; enough is [fil]tered off to make half a gallon of infusion, in whi[ch] dissolve 7 pounds of granulated sugar.

Chocolate. — Baker's chocolate, 4 ounces; d[is]solve in 20 ounces of boiling water, and dissolve [in] this 1 pound of granulated sugar. — *Druggist's C[ir]cular.*

Tonic to be used with Soda-water. — [A] good tonic for the above purpose may be prepared [in] the following way. A tincture is made from —

Brown Calisaya bark	2 pounds.
Gentian	¼ pound.
Well-cleaned orange-peel	¾ "
Alcohol of 60 to 70 per cent.	8 quarts.

This is mixed with 2½ quarts of cinnamon wat[er], when it will present a refreshing and strengtheni[ng] beverage if taken with soda and Seltzer water. — *Druggist's Circular.*

Boston Journal of Chemistry.

Volume V. BOSTON, AUGUST, 1870. Number 2.

Familiar Science.

A DANGEROUS WATER-PIPE.

Attention has been called several times in the Journal to the dangerous character of the *galvanized iron pipe*, when employed for conducting water to be used for culinary purposes. Instances of severe poisoning from the use of this pipe are continually coming to our notice, and we are led once more to caution our readers against it. It is almost a crime for dealers and manufacturers to recommend this zinc-covered iron pipe for water conduit, as they thereby jeopardize the health, and perhaps the lives of purchasers. When this pipe comes from the hands of the manufacturers, it has a fresh, clean appearance, and to those who do not understand the nature of the covering the idea is conveyed that it will not oxidize or rust, like ordinary iron pipes. But this is an error; it will rust even more rapidly than clean iron in most localities. The superficial covering of zinc is rapidly decomposed under the influence of ordinary pond and spring waters, and the oxide, carbonate, and chloride of zinc are formed, which salts are of a deleterious or poisonous character. This covering of zinc on the interior is attacked immediately when water is allowed to flow through, and in some instances we have known it to be entirely removed in forty-eight hours. The insoluble carbonate of zinc is seen to float upon the water in the tea-kettle, and other water vessels used in families, and this has often created alarm, where no suspicions previously existed. We hope the newspaper press throughout the country will caution their readers against the use of this pipe for water supply.

DUST UNDER THE MICROSCOPE.

Among specimens of dust from various localities which we have recently examined under the microscope, one was procured at the Springfield Armory. With a Tolles $\frac{1}{4}$ inch objective, the impalpable dust appeared to be composed mostly of fragments of iron and steel, but under the power of a $\frac{1}{5}$, the dust was seen to be made up of particles of *emery* as well as of various kinds of metals. This came from the polishing wheels used in the works. These fragments, too small to be distinguished by the naked eye, and floating about in the rooms occupied by the workmen, have sharp, cutting edges and jagged points, frightful to look at under a high magnifying power. We presume that but few, if any, find their way far into the respiratory organs, as the barriers which nature has interposed afford almost complete protection against injury from this source. If it were otherwise, many of our industrial pursuits would have to be abandoned, as they would be fatal to life. The dust from shoe factories affords much that is interesting to study. The fragments are all from organized substances, principally from leather. The filaments are twisted and convoluted in a curious manner, and some of them appear like snakes and lizards. The air in shoe factories is constantly loaded with these infinitesimal particles.

CHEMISTRY OF THE HUMAN BODY.

If we could subject the body of an adult person, weighing 154 pounds, to the process of chemical analysis, and then set down the results in the usual way, it would read about as follows: —

	lbs.	oz.	grs.
Oxygen	111	0	0
Hydrogen	14	0	0
Carbon	21	0	0
Nitrogen	3	8	0
Phosphorus	1	12	190
Calcium	2	0	0
Sulphur	0	2	219
Fluorine	0	2	0
Chlorine	0	2	47
Sodium	0	2	116
Iron	0	0	100
Potassium	0	0	290
Magnesium	0	0	12
Silicon	0	0	2
	154	0	0

The oxygen and hydrogen, for the most part, are combined in the body in the form of water; of this compound there would be about 110 lbs. The carbon is mainly contained in the fat; the phosphorus and calcium exist in the bones; the other minerals, in the juices of the flesh and in the blood. Of course the statements as given are but a rude approximation to the truth, but they are, nevertheless, sufficiently exact to afford a tolerably correct idea of the nature of the substances, and the amounts which enter into the human organization.

From this presentation, it will be seen that the body holds sufficient water at all times (about 14 gallons) to drown the individual, if it were contained in a suitable vessel. Under ordinary circumstances six pints of this water leave the system each day. If we drink largely, of course an increased quantity is eliminated through the excretory organs. This liquid finds its way into the system through the food and drink. Considerably more than half the bulk of all the bread, meat, and vegetables used as food is water. There is no other substance but water which remains unchanged after entering the body. Under the terribly destructive influence of vital chemical action, all other agents and bodies are torn asunder, and from their elements are formed new compounds of most strange and complex natures; water flows through our life; as it flows from mountain cataracts and meadow springs, unchanged and unchangeable, save in its physical aspects and condition. It is made capable of holding in solution all the nutrient and effete principles which enter or which are rejected from the human organization, and it is the medium through which it is built up and torn down. Life and death are alike dependent upon its agency.

Of phosphorus, every adult person carries enough ($1\frac{3}{4}$ pounds) about with him in his body, to make at least 4,000 of the ordinary two-cent packages of friction matches, but he does not have quite sulphur enough to complete that quantity of the little incendiary combustibles. This phosphorus exists in the bones and in the brain, and is one of the most important constituents in the body. Every schoolboy is acquainted with those strange metals, sodium and potassium, for he has seen them flash into a brilliant flame when thrown upon water. The body contains $2\frac{1}{4}$ ounces of the former, and a half ounce of the latter metal; enough for all needed experimental purposes in the schools of a large city. The 12 grains of magnesium would be ample in quantity to form the "silver rain" for a dozen rockets, or enough to create a light which under favorable conditions could be seen for a distance of twenty miles.

Our analysis disproves the old vulgar notion, that the blood of ten men contains iron enough to form a plowshare. The 100 grains of metallic iron found in the blood of a healthy adult would be sufficient to make a good-sized penknife blade, but no useful implement of a larger size. There is one important element associated with iron in the blood, which does not appear in the "analysis," and that is manganese. This element has not been recognized until a comparatively recent date, and its importance has been strangely overlooked. At a future time, under the medical head, we shall call attention to its important therapeutical relationships.

Probably no fact in medical or chemical science is more widely understood than that there is "iron in the blood." As a fact it is no more remarkable than that this fluid holds potassium or sodium, or that the brain is permeated with phosphorus. The popular curiosity and interest regarding iron as it exists in the circulation have been excited by the venders of quack remedies alleged to contain some combination of the element. While there is much that is very absurd in the statements popularly presented, it is impossible to overlook the importance to the well-being of the individual of the few grains of iron found in the blood. If the quantity is diminished from any cause, the whole economy suffers serious derangement. We have reason to believe that when the normal quantity (about 100 grains) is reduced 10 per cent. the system is sensibly affected, and the health suffers. How sensitive to all the chemical reactions going on within and around, is this complex machine which we call the body!

But iron, among the mineral constituents of the body, does not stand alone in its important

relationship. The metals exist combined with other bodies, or they are locked up in the form of salts, which are vital to the economy. There are five pounds of phosphate of lime, one of carbonate of lime, three ounces of fluoride of calcium, three and a half ounces of common salt, all of which have important offices to fill. Not one of them must be allowed to fall in quantity below the normal standard. If the lime fails, the bones give way; if salt is withheld, the blood suffers, and digestion is impaired; if phosphorus is sparingly furnished, the mind is weakened, and the tendency is towards idiocy.

Whence do we obtain these extraordinary metals and mineral substances which are diffused through the body? It is certain that among the dishes found upon our tables, none contain phosphorus, lime, iron, or magnesium, in their isolated condition. In the food we daily consume these minerals are found, and they constitute a part of the materials of its structure. A pound of wheat, of which we make our bread, holds a quarter of an ounce of mineral substances; a pound of potatoes contains the eighth of an ounce; cabbages, lettuce, apples, pears, strawberries, etc., also contain considerable quantities. Beef and other meats contain about four pounds of minerals in each hundred, and in the juices there are certain remarkable agents which are crystallizable, which have an alkaline reaction, and which unite with acids to form salts. These are creatine, creatinine, osmazome, etc. We hardly know where to class these agents, but they are undoubtedly of the highest importance in nourishing our bodies.

In case of deficiency of mineral compounds in the economy, it is possible to supply a part of them by the use of the substances themselves, but there are others which can enter only through the food.

Common salt (chloride of sodium) furnishes directly and readily the sodium salts and compounds. Iron can be supplied to the blood by administering it in various forms and combinations, or by giving the pure metal in powder.

Perhaps lime in some of its soluble forms is assimilable, and the same may also be said of phosphorus, as held in the weaker chemical combinations, as in hypophosphorous acid, and in the alkaline hypophosphite salts. If invalids who need the lime and phosphorus compounds would use whole wheat bread, they would secure the mineral food in a perfectly natural way. In the outer covering of the wheat berry, for some good reason, those elements are mainly stored up, and if we sift out and throw away the bran, we deprive ourselves of a most essential portion of the grain.

In the extract of beef, or in the isolated juice of beef, are found enormous quantities of minerals in a perfectly assimilable condition. In one hundred pounds of good dry extract of beef, made by evaporating the juices, there are contained 21 pounds of the most important agents needed in the animal economy. We would suggest to physicians and invalids the use of this beef extract in all cases where the system is suffering from deficient nutrition, or where there is any weakening of the vital powers through an insufficient supply of the mineral or nutritive agents essential to perfect health.

THE PLANET SATURN.

SATURN is, on the whole, the most interesting member of the planetary society which recognizes the sun as its "head centre." It is the largest of the group, with the single exception of Jupiter, being nearly 70,000 miles in diameter, and having a bulk at least 650 times that of our own little planet. But it is its wonderful system of rings, and its retinue of attendant orbs, that specially distinguish it, and almost raise it to the dignity of a sun. The eight moons, one of which is larger than Mercury and about as large as Mars, are equal in number to the sun's family of planets; and as the sun has, in addition to these, a ring of asteroids or minor planets, so Saturn has a more compact ring composed of myriads of minute satellites circling about itself in intertwining orbits. This complex system revolves round the sun, at a mean distance of about 875,000,000 miles, in a period of almost 30 years. The axis of the planet is inclined at an angle nearly the same as that of our earth, so that it has a change of seasons, as we have; but each season is, of course, about thirty times as long as each of ours. The polar day and night, instead of being only six months long, "drag their slow length" through fifteen of our years. On the other hand, the ordinary "day" of the planet, or the time in which it turns on its axis, is less than half the length of ours, or a little more than ten hours. At its equator, the sun hurries through the heavens and sets five hours after it rose, and after a night of five hours — a night whose sky is lit up by the luminous arches of the ring-system, and by the varied phases of the eight moons — the brief darkness vanishes before the returning dawn.

The ring-system is broad and flat, and is divided, by a gap some two thousand miles wide, into two concentric rings, of which the inner is the broader and brighter. These two rings are themselves divided in the same way, but these divisions, with the exception of one in the middle of the outer ring, do not appear to be permanent. Within the inner bright ring there was discovered, about twenty years ago, a dusky ring, through which the body of the planet can be seen as through a veil of crape. As the divisions between the rings are not absolutely black, it is probable that the little satellites which make up the ring-system are spread throughout its whole width, being crowded thickly together in the bright rings, and scattered more sparsely in the dusky ring and the apparent gaps between the rings.

As the rings are directly over the planet's equator, they are inclined to the plane of its orbit, and of the earth's orbit, by a considerable angle; and as this inclination is preserved throughout the revolution of the planet, the appearance of the rings, as seen from the sun or from the earth, varies remarkably. Sometimes they appear as a broad ellipse, sometimes as a mere line of light barely discernible with the most powerful telescopes, and sometimes they disappear entirely. These phases of the rings are illustrated in the first of the accompanying figures. In two positions of the planet, the plane of the rings passes through the centre of the sun, and only the outer edge is illumined. As the ring is estimated to be about one hundred miles thick, and as this thickness, at the distance of Saturn, would appear no greater than that of a good-sized pin two miles off, the delicate line of light can be discerned only by the best telescopes. The rings were in this position in 1848 and 1862, as marked in the figure. Now, if some time before the rings were situated as in 1848 the earth were at *A*, the plane of the ring would pass between the earth and the sun, so that the dark side of the rings would be turned toward us, and they would of course disappear. The same thing would happen if the earth were at *B* some time after the rings were situated as in 1862.

After passing the positions marked 1848 and 1862, the surface of the rings gradually comes more and more into view, until it is seen as a broad ellipse. This happened in 1855 and 1856, and we have just reached another of the periods when the rings are most favorably situated for observation. The planet, as viewed through a good telescope at the present time, exhibits the general appearance shown in the lower part of our second figure, which represents it as seen in March, 1856. Of course, the side

of the rings now visible is the one that was then turned away from us and from the sun; as will be evident from an inspection of the other figure. The other view of the planet given in our second figure was taken in November, 1852, and will serve to show how gradual are these changes in the position of the rings. It will be about four years before the planet, journeying onward in its vast circuit about the sun, will again appear as in that picture.

It will be observed that the body of the planet, in these two views, is marked with shaded belts parallel to its equator. They are represented rather coarsely in the wood-cut; and, indeed, no wood-cut could convey any adequate idea of their delicate beauty. Under ordinary circumstances the only colors distinguishable on the surface of the planet are white and faint yellow, but under the most favorable conditions of air and instrument these change into well-marked hues of more varied character. The most beautiful picture of Saturn that we have ever seen appeared in an English magazine, *The Student*, as an illustration of a paper on the planet, by Mr. Browning, the optician. It was a steel engraving, exquisitely colored with yellow, orange, red, purple, and blue, but the artist himself declares that it is a very imperfect portraiture of the ringed planet. "The tints I have used," he says, "are the nearest I could find to those seen on the planet, but there is a muddiness about all terrestrial colors when compared with the colors of the objects seen in the heavens. These colors could not be represented in all their brilliancy and purity, unless we could dip our pencil in a rainbow, and transfer the prismatic tints to our paper."

RECIPES FOR HOME USE.

Maple Beer. — To four gallons of boiling water add one quart of maple syrup, half an ounce of essence of spruce, and one pint of yeast. Let it ferment for twenty-four hours, and then strain and bottle it. In a week or more it will be ready for use.

Raspberry Vinegar. — Add half a pint of good vinegar to every quart of raspberries, and let them soak for two or three days; then bruise the berries, express the liquid, and to each pint add one pound of sugar. Boil it for twenty minutes, skim it, and when thoroughly cool, bottle it.

To get rid of Roaches. — Sprinkle powdered borax in the places where they congregate. This is one of the cleanest and safest means of putting an end to their visits.

Cottage Cheese. — Pour boiling water from a tea-kettle spout into the pan containing the loppered milk, beating it all the time with a spoon, until it begins to granulate and the whey separates. About one fourth of the quantity in hot water is usually sufficient. Then empty it into a colander, and let it drain about ten minutes. Pour on a quart or two of cold water, and as soon as this drains off, apply salt enough to give it an agreeable taste. Some persons prefer the addition of sweet cream when served.

To keep Flowers fresh. — Add to the water in which they are kept a small quantity of a solution of carbonate of ammonia and a few drops of one of phosphate of soda. Also cut off the ends of the stems for about half an inch, with a sharp knife, every other day. If these directions are followed, the flowers may be kept as long as if they had remained on the parent plant.

FREAKS OF LIGHTNING.

A correspondent in Chelmsford, Mass., sends us the following account of the pranks played by the electric fluid in a case which came under his personal observation: —

"The lightning entered the top of an old-fashioned kitchen chimney, passing down until it reached the flue in the oven, carefully swung open the oven door, leaped across the kitchen, shivered a board at the sink, and passing down a lead pipe, finally disappeared in a brook from which soft water was brought into the house through the pipe. The main chimney was utterly demolished, as we might suppose it would be by a shell exploded within it. In the oven a brown earthen bean-pot and a tin can of burning fluid stood in contact, just in front of the door, and the bean-pot was perforated on each side at opposite points by an opening, oval in shape, into which I could just insert the end of my little finger. These openings could not have been cut by any tool so smoothly as they were cut by the lightning. Not a brick was displaced in the oven, nor was the can of fluid disturbed, and neither the bean-pot nor can was moved in the least. The lead pipe was melted upon one side as if a very hot iron, three quarters of an inch in diameter, had been drawn over it, but was otherwise uninjured."

SCIENCE AND RELIGION.

The following is an extract from the remarks of Bishop Temple (formerly Head Master of Rugby School) at a recent Exhibition of the Plymouth School of Science: —

"I have a very real conviction that all this study of science and art comes from the providence of God, and that it is in accordance with his will that we should study his works; that as He has given us a spiritual revelation in his Word, so also has He given us a natural revelation in his creation, and that when we look back upon the records of His spiritual revelation itself we shall find evidence enough that He puts a real value on scientific studies; for we know that in the pages of the Bible the wisest of men, supplied with wisdom by God's own order, was the King of the Hebrews, Solomon. And what did his wisdom consist in? We find that he did not confine himself simply to the study of spiritual revelation. He spoke of trees, we are told; he evidently studied botany, far and wide. In fact, he was precisely doing, when he acquired the wisdom which God gave him, what this school is intended to do for you. I am convinced that God's Word has nothing to lose, but everything to gain, by a true and careful study of God's works. The more light we get, the more true discipline of our intellect by the study of all those things that God has scattered in such profusion around us — all their wonderful order and wonderful beauty — so much the better shall we be able, not only to serve Him in our affections, but also understand the meaning of his spiritual revelation. I am convinced that all light, of whatever kind, is good, and comes from God — that all knowledge comes from Him, and can be used in his service — that nothing that really adds to our knowledge of the world is for one moment to be despised; but, on the contrary, it should be the effort of myself, and of all who undertake to instruct our brethren in religious truth, to show that we feel that religious truth and secular truth are not only capable of being reconciled, but really come from the same God, who is the God of all truth."

WHAT IS DONE WITH OLD TEA-GROUNDS IN CHINA.

We notice the practice of hoarding up the leaves of tea, drawn in tea-shops and private families, and disposing of them to parties who make it a business to manipulate and prepare them for the foreign market, has made its appearance in Suchow, and other interior cities, where large quantities may be seen drying on the street any bright day. This method of adulteration has been extensively practiced at Shanghai for many years, and some time since provoked a proclamation from the taoutai forbidding it; as in many other instances, however, the prohibition had only a temporary influence, and instead of abating the evil, has encouraged its removal, or rather introduction, into other cities. The Chinese often wonder why foreigners like some kinds of their tea so highly colored as to require the application of almost deadly quantities of Prussian blue, and refuse to buy unless so medicated. Chinese tea for domestic use is never drugged, but to the uninitiated the marvel is still greater, as to what possible use the exhaustively drawn tea-leaves from the shops can be put either by natives or foreigners. It may be true that much of it is disposed of to the poorer classes with a slight mixture of good tea, but as a general rule, it is designed and prepared expressly for the foreign market. — *Shanghai News Letter.*

A CHEMIST'S VALENTINE.

I love thee, Mary, and thou lovest me.
Our mutual flame is like the affinity
That doth exist between two simple bodies.
I am potassium to thy oxygen;
'Tis little that the holy marriage vow
Shall shortly make us one. That unity
Is, after all, but metaphysical.
O! would that I, my Mary, were an acid —
A living acid; thou an alkali
Endowed with human sense; that, brought together,
We both might coalesce into one salt,
One homogeneous crystal. O, that thou
Wert carbon, and myself hydrogen!
We would unite to form olefiant gas
Of common coal or naphtha. Would to heaven
That I were phosphorus and thou wert lime,
And we of lime composed a phosphuret!
I'd be content to be sulphuric acid,
So that thou mightst be soda. In that case
We should be Glauber's salt. Wert thou magnesia
Instead, we'd form the salt that's named from Epsom.
Couldst thou potassa be, I aquafortis,
Our happy union should that compound form,
Nitrate of potash — otherwise saltpetre,
And thus, our several natures sweetly blent,
We'd live and love together, until death
Should decompose this fleshy Tertium Quid,
Leaving our souls to all eternity
Amalgamated! Sweet, thy name is Briggs,
And mine is Johnson. Wherefore should not we
Agree to form a Johnsonate of Briggs?

The Arts.

THE SPREAD OF INVENTIONS.

Some of our contemporaries have called attention to the rapidity with which certain important inventions have matured and have been spread throughout the civilized world. They refer us to the progress of steam navigation; to the development of photography, and the great industrial importance it has gained in the brief time that has elapsed since the first discoveries of Daguerre and Talbot; to electro-plating and kindred forms of electro-metallurgy, the birth of which dates back only about twenty years; and to the electric telegraph, which, within the memory of even the younger men of the present generation, spun the first thread of that magic network which now spreads through every land and every sea.

Now, it is true enough that these great practical discoveries of the age have spread thus rapidly, but it is only in our own day and generation that this has come to pass, and even now we might note important exceptions to the general rule. If we look back through several centuries, we shall see that improvements in the

arts have travelled very slowly from one land to another. In fact, they have rarely been propagated except by conquest or emigration.

The manufacture and use of sugar were known in Spain in the 9th century, but it was not till five hundred years later that they had reached England. The silk manufacture is even simpler than that of sugar, and yet it required 1,200 years to make the journey from Constantinople to London, and 200 years more to cross the Atlantic to our own shores. The progress of woolen and cotton manufactures around the world was equally slow.

This has been true, not only of "great inventions," but of some of the simplest and most convenient things ever devised. The earliest mention of chimneys, such as are used in our day, is in a Venetian inscription, which states that some were thrown down by an earthquake in 1347. But they could not have been introduced into England until the 16th century, since old Holinshed mentions them among the growing luxuries and corruptions of his day. Forks were first known in Italy towards the end of the 15th century. It was a hundred years before they came into use in France, and nearly a hundred more before they had travelled as far northward as Scotland. Their introduction into England was at first ridiculed as a piece of affectation and effeminacy. In one of Beaumont and Fletcher's plays, "your fork-carving traveller" is spoken of with great contempt, and Ben Jonson, too, joined in the laugh against them.

In repeated instances, the progress of inventions has been thus resisted by the popular clamor, and even opposed by popular violence. The first man who appeared with an umbrella in the streets of London drew down upon himself a pelting shower of mud and stones, which was worse than the rain against which he had spread the new-fangled protection. The old way of making boards was by splitting up the logs with wedges; and clumsy as the method was, it was no easy matter to persuade the world that there was a better. Saw-mills were first used in Europe in the 15th century. In 1663 a Dutchman built one in England, but the public outcry against it was so vehement that he was soon obliged to decamp; and for the next hundred years no one ventured to repeat the experiment. In 1768 a rash adventurer began to erect another mill, but a conservative mob gathered at once and tore it down. Many instances of the kind might be given if we had the space for them.

These facts prove very clearly the utility of the international exhibitions of the products of art and invention which began at the "Crystal Palace" in London, in 1851, and have already become one of the "institutions" of the time. They show that it is well for nations, as for individuals, to come together now and then, for the purpose of comparing and communicating the results of their experiments in the various departments of science and art.

A Big Ship. — The largest merchant ship in the world, next to the *Great Eastern*, is the *Italy*, just built at Govan (Scotland) for the National Steamship Company, and intended for their service between Liverpool and New York. She is fitted to carry 100 first-class and 1,500 steerage passengers.

MEMORANDA IN THE ARTS.

Slating for Blackboards. — The best thing for the purpose consists of pulverized slate or quartz made into a thick liquid with silicate of soda, or "water glass." This may be applied to boards or plaster with a brush, like ordinary paint. It produces a surface which is very much like the natural slate, while it costs much less.

Gold Ink. — Rub genuine gold leaf with honey on a plate of agate or ground glass by means of a flat pestle, until the whole presents a uniform mass, in which no distinct particles of gold can be recognized. This mass is carefully removed into a vessel with water, which will dissolve the honey, and leave the gold in a finely divided state behind. The water has, according to the size of the vessel, to be renewed twice or three times, when all the saccharine matter will have been washed away. The remaining gold is then mixed with a sufficient quantity of a solution of gum arabic, shaken well, and is now ready for use. The writing is to be rubbed, after drying, with a flat piece of ivory, when it will present the lustre of pure gold. Silver ink is prepared in the same way.

Another so-called "gold ink" is made by rubbing scales of iodide of lead with mucilage. If it is not dark enough, add a little iodine. Shake well before using.

Preserving Timber by Charring. — The general belief that the charring of timber promotes its durability, does not appear to be well-founded. Experiments have shown, on the contrary, that the charred timber decays sooner than the uncharred. Two posts split from the same log, one of which had been charred and the other not, were set in the ground side by side, and the charred post was the first to rot. The same fact has been noticed in railroad ties, and other timber exposed to variation of moisture and heat. The charcoal on the surface does not itself decay, but as it is not impervious to water, it permits the moisture to penetrate to the uncharred wood beneath, and decay begins *there*. When this has taken place, the covering of charcoal is of no service whatever.

Water-proofing Woven Fabrics. — The recipes we have lately published have attracted some attention among our readers. One correspondent inquires whether cloth treated with the lead solution can be worn in safety next to the skin. When the fabric is to be used for under-garments, metallic salts should not be used in water-proofing it. The *Moniteur des Fils* has recently given several new processes in which no lead is employed. The following is for woolen goods: —

Dissolve on the one hand $\frac{1}{4}$ pound of white Marseilles soap in two gallons of water, and on the other hand 6 ounces of alum in $2\frac{1}{2}$ gallons of water. Both solutions are heated to about 195° F. The goods are then passed several times through the soap liquor, then through the solution of alum, and lastly dried in the air.

The same proceeding is applicable to cotton goods, but double the above quantities of the various ingredients must be taken. Linen requires three, and silk four times this amount.

The following is for linen, hemp, and cotton fabrics: —

One pound of white soap is dissolved in 13 gallons of water, which must be heated, without however raising it to a boil. $2\frac{1}{4}$ pounds of alum are dissolved in a similar quantity of water. To this solution, $2\frac{1}{2}$ ounces of gelatine are added, which have been previously dissolved in water. Lastly, the solution of soap is mixed with that of alum. Enter the goods and distribute them in the warm but not boiling liquid. When they are thoroughly impregnated, hang them up by one end, and allow the water to drain off.

The following is the same in principle as the one given in our June number, sulphate of lead being formed in the fibre of the cloth: —

Linen, hempen, and cotton goods may be treated 4 hours in a sufficient quantity of water, containing an ounce of sulphuric acid in 2 gallons of water. After the drying of the linen, it is immersed in a liquid, containing half an ounce of sugar of lead in a quart of water, and left in for twelve hours. Drying concludes the operation.

Interesting to Candy Eaters. — At a place called Kaolin, in South Carolina, there is an immense deposit of pure porcelain clay. Thousands of casks of this clay are sent to market, and it is generally understood that the greater part of it goes to the candy manufacturers of New York. The adulteration is a harmless one, but it is a cheat, and is readily detected by the method which we gave in a former number, the sugar being soluble in water, while the clay is insoluble.

COTTON-SEED OIL.

The manufacture of this oil in the United States is increasing enormously, and, according to the *Rural Carolinian*, now reaches the high figure of 90,000 gallons a week. It is chiefly used for adulterating other oils, as linseed, lard, olive, and sperm. Its only other uses are for mixing putty, for which it answers better than any other known oil, and for curing tobacco, in which it has replaced the *bene* oil formerly imported for that purpose. In a former number of the Journal we referred to its mixture with olive oil, and to the probability that it may hereafter become a substitute for that oil for culinary purposes. The crude oil is of a very dark red color, which it derives from a sort of resin, which can be seen in black specks, in the kernel of the seed, with the naked eye, and the presence of this resin causes much trouble in refining the oil. A convention of the manufacturers of cotton-seed oil is about being held in New York city, to consider various subjects connected with the business, and especially to find legitimate uses for the oil. It is claimed that fifty per cent. of it, mixed with linseed oil, is better for painting than the pure linseed, as it dries as rapidly, and gives a coat more elastic and less liable to crack or peel off. As a soap stock, it also does well, when mixed with other oils, but alone it does not harden readily on the addition of salt, as other oils do.

THE ELECTRIC LIGHT AT SEA.

The steamships of the French line between Havre and New York are now furnished with electric lanterns for use at night. A correspondent of the *Telegrapher*, in a visit to Sandy Hook, a week or two ago, heard the veteran Farrell at the telegraph station describe his first introduction to the electric light as thus employed: —

"One night, while on the lookout (as he always is, for he sleeps but four hours out of the twenty-four, and those in the day-time), a thick fog set in, through which he vainly endeavored to get sight of any vessel to the seaward. The fog bells could be heard from their different stations, and the light-houses on the Hook shed their rays dimly but a short distance. Suddenly a great stream of light pierced through the dense fog, forming, as Farrell described it, 'a streak miles in length,' illuminating the highlands — then it shifted across the Hook, and, as it swept athwart the telegraph station, a glimpse of its intense light was perfectly dazzling; then it shot a long way up the harbor, and then over towards Long Island. It appeared to cut the fog in pieces, and seemed to leave a wake of light over the vast region of space through which it traversed.

Farrell was on the point of telegraphing to the city that a large ship was on fire, for never before had such a brilliant light been seen in the neighborhood of the Hook; and, under the circumstances, he would have been justified in so doing, but he is a cautious man as well as prompt. But soon he heard sounds from the steamer which convinced him that it was the St. Laurent, and instead of creating an excitement throughout the country, by announcing 'a steamer on fire below New York harbor,' he simply announced the arrival of the St. Laurent. No one can be more earnest in commendation of this electric light than this old veteran. He says there is nothing like it on the water — that it is the only light that penetrates successfully a dense fog; and no one is better qualified from experience, both at the Hook and also at Cape Race — that home of fogs — than he to judge of the merits of this triumph over the elements of darkness. With this light at its bows a vessel's course can be seen by those on board in the thickest weather for miles ahead — thus rendering collisions with vessels or icebergs almost an impossibility. Perhaps the use of an electric light might have saved the City of Boston from becoming the tomb of so many valuable lives."

Let the Boys have Tools. — We heartily indorse the following, which we extract from an article on "Mechanical Recreations" in the *Scientific American*: —

"Every man who can afford it should supply his boys with tools, and a room where they may be used and cared for. A boy takes to tools as naturally as to green apples, or surreptitious and forbidden amusements; and ten to one if he has a chance to develop his mechanical tastes and gratify them to their full extent, his tendencies to vicious courses will remain undeveloped. Such a result is enough to compensate for all the expense and trouble the indulgence we recommend would entail; while the chances that the early development of his constructive faculties may in this mechanical age be the means by which he may ultimately climb to fame and fortune are not small."

The Introduction of Mahogany into England. — Our new neighbor, *The Cabinet Maker*, tells the following story in the course of an interesting article upon Mahogany: —

"A physician of the name of Gibbons, who resided in London, received in 1724 a present of some mahogany planks from his brother, a West India captain. Dr. Gibbons was then building a house, and he desired his carpenter to work up the wood. The carpenter had no tool hard enough to touch it; so the planks were laid aside. The doctor's wife, after the house was finished, wanted a candle-box, and the mahogany was again thought of. A cabinet maker of the name of Wollaston was applied to; and he also complained that his tools were too soft. But he persevered, and the candle box was at length completed — after a rude fashion, no doubt. The candle-box was so much admired, that the physician resolved to have a mahogany bureau; and when the bureau was finished, all the people of fashion came to see it. The cabinet maker procured more planks, and made a fortune by the numerous customers he obtained. From that time the use of mahogany furniture went forward amongst the luxuries; — and the drawers and bureaus of walnut-tree and pear-tree were gradually superseded in the houses of the rich."

Oxygen Prepared without Heat. — A mixture of the peroxides of lead and barium may be kept for any length of time without being decomposed. If weak nitric acid be added, peroxide of hydrogen is generated, which is immediately decomposed by the oxide of lead into water and pure oxygen.

Agriculture.

A NEW "DODGE" AMONG FERTILIZER MAKERS.

A large number of farmers have made inquiries of us regarding a new fertilizer manufactured by Mr. Dodge Hayward, of — we don't know where; we are asked repeatedly what we "think of it." Well, here is the "*analysis*" of the compound, as found upon one of the packages, and of course we have the means of knowing just "what there is in it:" —

Aqua and organic matter	10.40
Carbonic acid	3.30
Oxide calcium	24.20
Phosphorus	1.00
Soda	12.00
Chlorine	10.10
Sulphuric acid	30.00
Oxide of iron	.60
Silex	8.40
	100.00

This "analysis" is placed upon packages in accordance with the "statute made and provided," and is very *clear*, — to those who understand it. It is not expected that purchasers will understand it. Let us examine it. 1. "*Aqua and organic matter;*" that is, being interpreted, water and peat, or muck. 2. "*Carbonic acid;*" this sounds well, but there is no free carbonic acid in it. Carbonic acid is a gaseous body, and cannot be retained in a powder. 3. "*Oxide of calcium;*" common quicklime. All right. 4. "*Phosphorus,*" one per cent. A very modest amount of this most essential element; but there is no free phosphorus in it. 5. "*Soda,*" twelve per cent. All right. 6. "*Chlorine;*" but there is no free chlorine in it. Chlorine is a gaseous body, like carbonic acid. 7. "*Sulphuric acid,*" or "oil of vitriol." But there is no uncombined oil of vitriol in it; if there were, 30 lbs. in each hundred pounds of the powder would be "death to crops." 8. "*Oxide of iron;*" a pinch in a barrel. All right. 9. "*Silex,*" or sand. All right. Now, let us put these acids, gases, and alkalies *together*, as they ought to be presented, and see what we get, and also see what they cost. The water and peat cost nothing, and are valueless. The carbonic acid, phosphorus, and sulphuric acid are combined with the "oxide of calcium" or common quicklime, and form carbonate, phosphate, and sulphate of lime, or gypsum. The chlorine is combined with the soda, and forms *common salt*. The other substances are of no account. Plainly stated, the mixture is made up about as follows: —

Moist muck	10 lbs.	cost 0.00
Gypsum	45 "	" 0.20
Salt	22 "	" 0.10
Carbonate and phosphate of lime	15 "	" 0.18
Sand	8 "	" 0.00
	100 lbs.	0.48

A very cheap batch this, — hardly worth talking and lecturing about all over the country. Its cost is less than $10.00 the ton, and its fertilizing value — not much. We believe it is sold at $27.00 the ton. The cunning "dodge," practiced by makers of fertilizers in obscurely stating the nature of their compounds, or in presenting the required "analysis," is worthy of notice. Instead of making a plain statement of the simple salts and substances which compose the mixtures offered for sale, they "get up" an elaborate ultimate analysis, which can be understood only by chemists, and often these statements are so "mixed and muddy" as to be entirely unintelligible to them. We shall have something more to say upon this subject at a future time.

THE VALUE OF STRAW AS FODDER.

In the remarks we have made regarding the value of dry corn fodder, it was stated that it has been put in mows with wheat straw in our barns, and that the straw and corn "butts" have been consumed together by our herd of cows, causing a copious and well sustained flow of milk during the winter months. These remarks have led to many inquiries from our farmer readers with regard to the nutritive value of wheat and other kinds of straw. It is certain that straw has been underestimated in this country by grain raisers, and that a source of profit has been to a considerable extent lost from this circumstance. One hundred parts of wheat straw, as produced under ordinary conditions in this country, contain —

Water	13.33
Oil, etc.	1.74
Albumen, etc.	1.28
Sugar, mucilage, extractive matters, etc.	4.26
Digestible fibre	19.40
Soluble inorganic matter	1.13
Insoluble proteine compounds	1.65
Woody fibre	54.13
Insoluble inorganic matter	3.08
	100.00

It will be seen that wheat straw contains about 30 per cent. of assimilable food, or food capable of nourishing animals. It contains as much albumen and proteine compounds as ordinary run hay. Woody fibre is however largely in excess, and there is a far less quantity of sugar, mucilage, etc., than in the hay of our meadows. The kind of straw which approaches nearest to good upland hay is oat straw, cut before it is fully ripe. The order in which the different kinds of straw stand relatively, as regards nutritive value, may be presented thus: —

Oat straw,
Barley straw,
Wheat straw,
Rye straw.

Unquestionably it will be for the interest of farmers in most sections to diminish the amount of straw used for litter, and increase its use for fodder. In many of the Northern States rye straw is of equal value with the best quality of timothy, as it is used largely for bedding horses in towns and cities. Of course, where straw commands such high prices, and is of such ready sale, it would be absurd to feed it to animals. We must not be understood in these remarks as holding to the view that any kind of straw can supersede the use of good hay and grain, but rather that it contains a sufficient amount of the elements of nutrition to make it a valuable substitute for these usually more costly products.

A milk-weed grows wild in California, the fibre of which is as strong as Manila hemp, and as fine as linen. It is believed that it can be utilized.

CLAM AND OYSTER SHELLS.

Having stated, in a note published in the *N. E. Farmer* of this city, that clam and oyster shells were of no value as fertilizing agents, a large army of correspondents immediately rushed to the rescue of the bivalve covering. The following reply was made to these intelligent writers: —

Editors New England Farmer: — I do not question the good intentions of your correspondents, W. H. Y., Mr. Phineas Pratt, and others, who are writing about the great fertilizing value of clam and oyster shells. However honest they may be, it is certain that they are confusing the minds of farmers, and thereby doing much injury to the interests of agriculture. Some months ago I stated in your journal that clam and oyster shells were not manurial agents: that they were composed of carbonate of lime, which is valueless.

This simple truth, which it would seem every intelligent New England farmer ought to understand, has caused this excessive literary activity among some of your patrons. The trouble with your correspondents is that they do not clearly understand the matters they are discussing. No one of your intelligent readers will expect me to make any formal reply to what has been written, as the views presented are too preposterous to be taken into serious consideration.

Mr. Pratt evidently considers *oyster shells* and *bones* of equal fertilizing value. He does not understand the difference between a *carbonate* and a *phosphate* of lime. He says, "where oyster shell beds are, *or* where *bone dust* is used, cabbages grow twenty years in succession," etc. He does not know the chemical difference between *hydrate* and *carbonate* of lime, or between oxide of calcium (caustic lime) and carbonate. Again, he says, "New Jersey owes half its fertility to *burning their rocks* and liming their lands once in seven years." As a statement, this is very absurd. Lime rock and oyster shells are no longer *carbonate of lime* after being *burned*. The carbonic acid is driven off by heat, and oxide of calcium is formed. This is a different agent entirely. The remark that "lime is the great thing wanting to bring back the fertility of the soil," is not true, but it may be noted as showing that Mr. Pratt regards lime (oxide of calcium) and oyster shells (carbonate of lime) as identical. It is certain that Mr. Pratt is not an authority in matters of agriculture involving chemical principles.

W. H. Y. falls into the same errors, and fails to understand the views of the writer he quotes. Neither Liebig, Stöckhardt, Johnston, Way, Boussingault, nor other chemist of any repute, ever stated that clam and oyster shells are manurial agents. The quotations made from two or three of the above named writers, regarding the fertilizing value of *lime*, have no bearing whatever upon the question at issue.

Let it be understood by soil cultivators everywhere, once for all, that clam and oyster shells *are not manurial agents, in any proper sense;* that they should receive no consideration at their hand as substances to be *bought* at any price. Writers who endeavor to make agriculturists believe to the contrary are doing that which is detrimental to their interests. James R. Nichols.

150 Congress St., Boston, *June* 4, 1870.

Colonel Baylor, of Georgia, has been experimenting upon the further utilization of the sweet potato. The results are very satisfactory. The articles produced in perfection are starch, dextrine, a very valuable article which may be called sugar-powder, and also a sweet, delicious vegetable flour.

HINTS FOR THE FARM AND GARDEN.

To Improve Blackberry and Raspberry Plants. — Mix equal parts of sawdust and stable manure, and place around the roots every fall before the snow comes. It tends not only to keep the roots warm during the winter, but the sawdust, by partially decomposing, furnishes a quantity of potash, which is a very requisite food for the growing plant. Grape vines may be treated in the same manner.

French Method of Tomato Culture. — As soon as a cluster of flowers is visible, the stem is topped down to the cluster, so that the flowers terminate the stem. The sap is immediately impelled into the two buds next below the cluster, which soon push strongly and produce another cluster of flowers each. When these appear, the branch to which they belong is also topped down to their level, and this is done successively. By this means the plants become stout dwarf bushes, not above eighteen inches high. In order to prevent their falling over, sticks or strings are stretched horizontally along the rows, so as to keep the plants erect. In addition to this, all the laterals that have no flowers, and after the fifth topping, all laterals whatsoever, are nipped off. In this way the sap is directed into the fruit, which is developed accordingly.

To Measure Corn in the Crib. — Multiply the length, breadth, and height together, in feet, to obtain the solid contents; multiply this product by 4 and strike off the right-hand figure, and the result will be shelled bushels, nearly.

Extempore Measures. — A box 4 inches square and 3.6 inches deep will hold one wine quart (57.75 cubic inches), very nearly. A box 5 inches square and 4.6 inches deep will hold half a wine gallon (within half a cubic inch). A box 8 inches square and 8.4 inches deep will hold a peck; and one 16 by 16.8 inches and 8 inches deep will hold a bushel, or 2,150.4 cubic inches. A box 22 by 21 inches will hold a wine gallon for each half inch of its depth, and may be made as deep as desirable. These measures can be very easily made by any one who knows how to handle tools, and will be found convenient for many uses.

SCHOOLS OF AGRICULTURE.

In the perusal of your article on "A School of Agriculture" some months since, I felt no small degree of pride at observing how far your views therein correspond with those presented by me, sixteen years ago, in the *Geneva (N. Y.) Courier*. I then advocated winter instruction by lectures and experiments, for farmers and their sons, who might come without any positive requirements of preliminary education, and who might return to their own homes to spend the working months of the year. My ideas were coupled with the suggestion, that the Trustees of Geneva College should, with the consent of the Legislature and of all parties interested, abolish their Medical Faculty, organize an Agricultural Faculty, and turn over to the latter the property then used by the former. John Delafield, who was then agitating the subject of an Agricultural College on the east side of Seneca Lake, was readily converted to my views, and promised me his cordial coöperation. I do not mean that my institution was to supersede his (where boys were to be put through a course of three or four years, at an annual charge of $300 for board and tuition of each), but his professors were every winter to give systematic instruction to farmers in the lecture-rooms of Geneva Medical College. My plans were approved by a portion of the Board of Trustees, but they were opposed by Bishop De Lancey; and the death of Mr. Delafield deprived them of his powerful support.

Three or four years ago, while conversing on this subject with the founder of Cornell University, he told me that he hoped to see established in Ithaca such a winter course of instruction for farmers as I had suggested in Geneva. It is in the vicinity of a great university, and with the aid of its faculty, that such a plan could be carried out most efficiently, and with the least money. But I would associate with them a number of thoroughly educated, practical farmers, like John Johnson, of Seneca Co., N. Y., and George Geddes, of Onondaga. Sumner Rhoades, M. D.

Syracuse, N. Y., *Feb.* 1870.

HUMAN BONES AS FERTILIZERS.

The manufacturers of phosphate of lime for artificial manures generally employ for the purpose the bones of animals. In this country, the battle-fields of the late war have furnished large quantities of horses' bones. Sometimes human bones are accidentally collected among the rest; but the care and reverence with which the dead on both sides have been buried prevent such unpleasant occurrences almost entirely. Not long ago, much indignation was caused in England by the report that cargoes of human as well as animal bones were shipped from the Crimea to the British manufacturers. How much foundation there was for the story we do not know. Certainly the objection of civilized people to seeing the remains of their fellow-citizens or ancestors brought into commerce is most natural.

The English manufacturers appear not to be satisfied with the supply of the bones of animals, either because it is not adequate to the demand, or because its scattered sources and the consequent expense of collection leave too little margin of profit. They have at last found a country rich in bones, and possessed of a population not too scrupulous to sell them. The mummy-pits of Egypt, containing thousands of tons of the bones of the ancient Egyptians, are now "worked" on a large scale. The bones are dug out, cleaned and sifted, packed in bags or bundles of two hundred pounds each, slung to the sides of camels, and transported to Alexandria, where they are shipped to England. The business affords a brisk trade to the modern Egyptians, and employs a large number of the population; in justice to whom we should add, that they are probably not descendants of the venerable worthies whose relics they put to such base uses.

It is curious to reflect that the phosphate of lime which once formed the frame of a member of the Egyptian aristocracy should, after a quiet repose of some thousands of years, enter upon a new career of usefulness in a distant land as an excellent manure for turnips and other garden vegetables, which may in turn furnish the necessary phosphate of lime to give backbone to the British aristocracy. Great Cæsar stopping a hole to keep the wind away is nothing in comparison!

What future tradesmen will grow rich, and what future turnips thrive, we wonder, on the tombs of Westminster and St. Paul's, or the vaults of Cologne Cathedral, or the ghastly sepulchre of the Capuchins at Rome? The more carefully the bones of the great or the sainted are preserved, the less likely, it would appear, are they to "rest in peace." — *Manufacturer and Builder.*

Beet Sugar. — Attempts are making to interest English farmers in the culture of the beet for sugar manufacture. In France the manufacture, already enormous, is rapidly extending. A large factory has lately been built not far from Paris, and pipes have been laid for a distance of twenty miles for collecting beet-juice from the surrounding country. This plan works well, and has been adopted in other localities. More than one hundred and fifty miles of such pipe are now in use.

Boston Journal of Chemistry.

JAS. R. NICHOLS, M. D., *Editor.*
WM. J. ROLFE, A. M., *Associate Editor.*

BOSTON, AUGUST 1, 1870.

PUBLISHERS' NOTICE.

All correspondence relating to the business of the Journal, remittances, etc., must be addressed, "Boston Journal of Chemistry, 150 Congress Street, Boston, Mass."

All correspondence relating to editorial affairs should be addressed to the Editor, 150 Congress Street, Boston.

THE JOURNAL GIVEN AWAY.

On receipt of the publishers' price of any one of the following periodicals, we will send *both the* JOURNAL *and that periodical* for one year. This offer applies to those persons only who are not already subscribers to the periodical selected.

THE ECLECTIC	$5.00
EVERY SATURDAY	5.00
THE NATION	5.00
NATURE (*London*)	5.00
N. Y. JOURNAL OF PSYCHOLOGY	5.00
AMERICAN NATURALIST	4.00
APPLETON'S JOURNAL	4.00
THE ATLANTIC	4.00
COLLEGE COURANT (*New Haven*)	4.00
THE GALAXY	4.00

NATIONAL HYGIENE.

WE are not so much ahead of the ancients in hygienic matters as we sometimes boast ourselves. As a writer in *Nature* reminds us, it is not alone in modern times and among enlightened nations, that "the art of preserving health" has received careful and intelligent study. Ancient Egypt and modern China may teach us certain lessons in sanitary science. The former furnishes us "one of the best instances of the power of cultivation in improving the condition of a country." The inundations of the Nile were in ancient times the source of fertility and health, but are now the cause of pestilential marshes, which make the region one of the most unhealthy on the globe. China, with its crowded population, has learned — what we have not yet learned — *to waste nothing.* There, what is taken from the earth is given back to it, every atom of sewage matter being employed as manure. The land is thus enabled to support an immense population, and to maintain its fertility from century to century.

The writings of Moses are full of admirable hygienic regulations, which were enforced by the severest penalties. These regulations are not only general but specific, "descending to the inmost details of every-day life; giving a regimen admirable in its adaptation to the climate of the countries for which it was intended; directing the burial of excrementa and refuse matter of all sorts in the earth; fixing the laws of marriage, of concubinage, of servitude, and of all social relations." The immunity of the Jews in the midst of the most fearful epidemics has been very remarkable; and M. Michel Lévy, one of the best modern writers on hygiene, ascribes it to their strict conformity to these sanitary regulations.

In ancient Greece and Rome the baths and gymnasia were hygienic institutions, of whose benefits all classes, high and low, regularly availed themselves. The water supply of Rome was more than 332 millions of gallons per day, or (as the population did not exceed a million) at least 332 gallons for each person, six times as much as modern London furnishes.

The writers of those early days had reduced hygiene to a system. Hippocrates gives excellent dietetic regulations for gymnasts, and for the sick. The titles of some of his works are "Food," "The Use of Liquids," "The Diet of Healthy People," "Air, Water, and Localities," and, as has been well said, they entitle him to be considered "the father of experimental hygiene."

Celsus and Galen likewise made hygiene a department of medicine, and treated it ably and intelligently in their writings.

It was not until the rational doctrines of these fathers of medicine were mixed up with the absurdities of alchemy, and their sensible methods were displaced by traditional and arbitrary modes of treatment, that hygiene came to be utterly neglected; and, as a result of the neglect, Europe was visited by frightful epidemics, compared with which the plagues of Athens and of Rome were trivial visitations.

The value of preventive measures in these epidemics was illustrated in the plague of 1719 — the last which was known in Europe. The epidemic was introduced into Marseilles by a ship that had been refused admittance into a Sardinian port. Sardinia was saved from the fearful visitation by this wise action on the part of its monarch, while Marseilles was ravaged by the fatal pestilence. More than 90,000 victims had fallen before its devastating progress was checked.

The mere diffusion of hygienic knowledge among the people does not suffice for the sanitary well-being of a nation. It is only when the government takes the matter into its own hands that the public health can be thoroughly cared for; and hence the necessity of Boards of Health, which may collect information with regard to the statistics and the causes of disease, and suggest how those causes may be removed or reduced to a minimum. Without such *scientific* guidance in dealing with questions pertaining to the public health, legislation is quite as likely to make matters worse, as to better them. When we are sick, we go to a physician — that is, if we are sensible people, — and a nation should act on the same principle, and not try to cure social diseases which it does not understand, with medicines of whose nature and effects it is ignorant. "Doctoring one's self," in serious cases, is poor policy for either an individual or a community.

THE EDITORS AT LAKESIDE.

THE members of the Massachusetts Association of Editors and Publishers, with their wives, are to be our guests at Lakeside in September, at the time of the ripening of fruits. We know of no class of men who are better deserving of a "good time," or who are more capable of merry-making, than Editors. If we are not called upon to repeat the exclamation so often made at Gloucester, "*Multum pluvium! multum pluvium!*" we think a "jolly good time" may reasonably be expected. Opportunity will be afforded for solving a curious "rule of three" problem, which may be presented thus: If a hundred doctors "disemboweled" three bushels of grapes in an afternoon at Lakeside last year, how many will twice the number of Editors "turn into pi" in the same length of time? We must patiently wait for the solution of this important problem, until autumn. Arrangements will be seasonably made for transporting and entertaining the company.

EDITORIAL NOTES.

DIET OF BELGIAN MINERS. — The diet of miners in Belgium, according to official reports, consists of 2 pounds of bread per day, about 2 ounces of butter, 1 ounce of coffee and chicory mixed, and in the evening potatoes and other vegetables to an amount not exceeding $1\frac{1}{2}$ pounds. They have meat on Sundays and holidays, but during the week they drink neither beer nor other fermented liquor. Coffee is their only beverage, with about ten per cent. of milk added. This, with the bread and butter, is all that is taken until the vegetable meal of the evening. This diet is less nutritious even than that of the monks of La Trappe, and is, in fact, below what is generally considered as essential to life and health; yet these workmen are hardy and healthy. The coffee contains but three per cent. of the nutriment in their daily rations, but, since it is pretty well established that this beverage diminishes the waste of the tissues, it may be a very important item in this remarkably meagre diet.

ANOTHER BIT OF NEWSPAPER SCIENCE. — A Boston paper favors us with the following in the way of scientific intelligence: "Astronomers predict that the present will be the hottest season experienced by the present generation. Their reason for this prophecy is the near approach of several planets to the earth." Our readers are aware that it has recently been proved that there is an appreciable amount of heat in the beams of the moon, but no astronomer has been wild enough to dream of detecting any warmth in the rays of the planets. We may add that it is not true that "several" of the planets will be unusually near the earth during the present season. These trivial objections aside, we do not know that there is any serious difficulty in the way of our accepting this "scientific" explanation of the hot weather we have been having.

THE PROGRESS OF REFINEMENT. — Most of our readers probably know that horses have been addicted to the unbecoming practice of going to bed with their shoes on. It will gratify them to learn that there is a prospect of an improvement in this regard. A company in Chicopee, Mass., are making an adjustable horseshoe, which can be taken off at night or when the horse is not being used, as readily as the boots and shoes worn by human animals. The "corks" of the shoes are also adjustable, and new ones can be fitted when the old ones are worn out. Hereafter, all steeds of really respectable character will doubtless insist upon being furnished with the improved style of shoe. The nag that retires to his strawy couch before his pedal

coverings are removed will be met with a unanimous *neigh* if he seeks admission to the "first circles" of equine society.

NATURAL SCIENCE IN SCHOOLS. — Carlyle, in a communication to the Edinburgh *Courant*, says: —

"For many years it has been one of my constant regrets that no schoolmaster of mine had a knowledge of natural history, so far, at least, as to have taught me the grasses that grow by the way-side, and the little winged and wingless neighbors that are continually meeting me with a salutation which I cannot answer as things are.

"Why didn't somebody teach me the constellations, too, and make me at home in the starry heavens which are always overhead, and which I don't half know to this day?

"I love to prophesy that there will come a time when, not in Edinburgh only, but in all Scottish and European towns and villages, the schoolmaster will be strictly required to possess these two capabilities (neither Greek nor Latin more strict), and that no ingenuous little denizen of this universe be thenceforward debarred from his right of liberty in those two departments, and doomed to look on them as if across grated fences all his life!"

We hope that the same "good time" may come on this side of the ocean as well. At present, our teachers are wofully deficient in this regard. Even those who attempt to teach the natural sciences are often only blind leaders of the blind. A man sometimes presumes to give instruction in astronomy when he cannot point out to his pupils such familiar constellations as Orion and the Lion, nor distinguish Jupiter from the Dog-star. We have known of such a case recently in one of our leading high schools, and we fear that it may not be a solitary one of the kind. In this instance, the plan of the text-book, which begins with the study of the constellations — which appears to us nothing more than "beginning at the beginning" — had to be modified to suit the disability of the teacher. But this is a subject that cannot be fairly treated in a brief note, and we shall recur to it in a fuller way hereafter.

WALLACE AND DARWIN. — It is well known that Mr. A. R. Wallace was an independent originator of the theory of "natural selection" with which Mr. Darwin's name has become identified. We took it for granted, therefore, that the new book on this subject by Mr. Wallace (recently published by Macmillan & Co.) was intended to set forth the author's claim to the credit of having enunciated this view of the origin of species, now so widely accepted among scientific men. But when we read the preface of the book we were pleasantly surprised to find that, so far from being an attempt to deprive Mr. Darwin of his laurels, it was a generous tribute to the rival discoverer of the famous "law." We give a few sentences from this preface, to show the modesty and the magnanimity of the man: "The present work will, I venture to think, prove that I both saw at the time the value and scope of the law which I had discovered, and have since been able to apply it to some purpose in a few original lines of investigation. But here my claims cease. I have felt all my life, and I still feel, the most sincere satisfaction that Mr. Darwin had been at work long before me, and that it was not left for me to attempt to write *The Origin of Species.* I have long since measured my own strength, and know well that it would have been unequal to that task. Far abler men than myself may confess that they have not that untiring patience in accumulating, and that wonderful skill in using, large masses of facts of the most varied kind, — that wide and accurate physiological knowledge, — that acuteness in devising, and skill in carrying out experiments, — and that admirable style of composition, at once clear, persuasive, and judicial, — qualities, which in their harmonious combination, mark out Mr. Darwin as the man, perhaps of all men now living, best fitted for the great work he has undertaken and accomplished."

RUSTING OF IRON. — Experiments made by Dr. Calvert, in England, show that moisture and oxygen are not the sole conditions of oxidation, but that carbonic acid must be associated with these in order to produce any marked effect. In dry oxygen, iron does not rust at all; in moist oxygen, very slowly; but in a mixture of moist carbonic acid and oxygen, the rusting is very rapid.

A CHANCE FOR INVENTORS. — A bill offering a premium of $5,000 for the invention of a successful steam plough has passed the Senate of California. The Illinois Central Railroad Company has had a standing offer of $20,000 for such a plough for several years past. Of course, these premiums are but a small part of the pecuniary reward which the inventor of such a machine is assured of.

ADULTERATION OUTDONE. — It is stated on good authority that cream of tartar has been sold in the New York market which did not contain a particle of cream of tartar, being composed of five sixths plaster of Paris, and one sixth sulphuric acid and starch. The very term *adulteration* assumes that there is at least some portion of the genuine article present, however extensively it may have been sophisticated; so that in this case we have something beyond the "utmost art" of adulteration properly so called.

LITERARY NOTES.

THE Second Volume of the *Journal of the Gynæcological Society* of Boston has been published by Mr. James Campbell, 18 Tremont St. The growing popularity of the periodical is shown by the fact that the bound volumes are having a good sale, while the subscription list is steadily increasing. It will be noticed that we furnish the *Journal* with our own for $3.00 per annum, the regular price of the former.

We make a similar arrangement in the case of *The Technologist*, which has now reached its sixth number. It has received emphatic commendations from the press in England as well as at home. The London *Engineering* says that it is "liberal in its tone, extended in its scope, well printed, fairly illustrated, and cheap — very cheap," and predicts for it "a long and successful career." The praise is deserved, and the prophecy a safe one.

The *Chemical History of the Six Days of Creation*, noticed in our last, is from the pen of Mr. John Phin, the editor of *The Technologist.*

Contributions to the Theory of Natural Selection is the title of the new book by Mr. Alfred Russel Wallace, to which we have alluded in our "Editorial Notes" above. It is made up of essays written during the last fifteen years, several of which are now printed for the first time. The titles of some of them are very enticing — "Mimicry and other Protective Resemblances among Animals," "The Philosophy of Birds' Nests," "A Theory of Birds' Nests, showing the relation of certain differences of color in female birds to their mode of nidification," and the like — and the essays themselves will not disappoint the reader who is thus attracted to them.

Macmillan and Co. have also published *The Population of an Old Pear-tree, or Stories of Insect Life*, from the French of E. Van Bruyssel, edited by Miss Yonge. It is piquant in style and graphic in illustration, and will serve to interest the young folks in entomological studies. The translation is better than that of some other French books of popular science that we could name, but it is not so good as it might be. Most of these books seem more "Frenchy" in their English dress than in the original, simply because the version is not properly *toned*, so to speak.

The Private Life of Galileo is much the best account of the man that has appeared in English. Although it purports to be confined to his private life, it contains many interesting details in regard to his scientific labors and his persecution by the Church. It is compiled principally from his correspondence and that of his eldest daughter, Sister Maria Celeste, nun in the Franciscan Convent of St. Matthew, in Arcetri. Many of these letters are charming for their simplicity and their mingled piety and filial devotion. Sister Maria looks after her father's linen collars and sends him cakes and sweetmeats, and while writing about these mundane matters mixes in little sermons in the most artless way. These glimpses of the every-day life of the times, would of themselves make the book very pleasant reading.

The Harpers have at length issued their long-promised reprint of Yonge's *English-Greek Lexicon* edited by Prof. Drisler. It is the first book of its class published in America, and it is so complete and admirable in all respects that it is sure to hold the field for a long time to come without a rival. No classical scholar can afford to do without it. In addition to the Lexicon proper, which has been immensely improved by Prof. Drisler's revision, the volume contains the whole of Arnold's translation of Pillon's *Greek Synonymes.* It is rather singular that no work on Greek synonymes has ever before appeared in this country. Trench's two series on the *Synonymes of the New Testament* have been reprinted here, but they are not properly an exception, as we are speaking of *classical* Greek. Another valuable addition to the original work is Prof. Short's Essay on the Order of Words in Attic Greek Prose.

Prof. F. A. March's *Comparative Grammar of the Anglo-Saxon Language* is also a work which does honor to American scholarship. It has no rival in English, and will at once take rank as a standard and an authority.

Christianity and Greek Philosophy, by Prof. B. F. Cocker, of the University of Michigan, is a profound study of the "relation between spontaneous and reflective thought in Greece and the positive teaching of Christ and his Apostles."

The History of Hortense, the daughter of Josephine and the mother of Napoleon III., is a new volume of "Abbott's Illustrated Histories," a series which we have found to be quite as attractive as fiction to juvenile readers, and, we may add, far more wholesome for them. Smiles's *Self-Help*, the new revised edition of which has been reprinted by the Harpers, is another book that boys always read with great interest, and there are few things that you can better put into their hands.

Hepworth Dixon's *Free Russia* has met with rough treatment at the hands of some of the critics, but it is generally admitted to be a full and trustworthy account of the present state of things in that great country. It is, moreover, a "live" book, and the Harpers have done well to give us an American edition of it. Messrs. Noyes, Holmes, & Co., the new firm at No. 117 Washington Street, have it, with all these other recent books.

☞ *We will send any book noticed in the* JOURNAL *to any address, postpaid, on receipt of the publisher's price, or as a* PREMIUM *for new subscribers, at the rate of* 25 *cents for each name sent us* WITH ONE DOLLAR. The prices of books mentioned above are as follows: —

Wallace's Contributions to the Theory of Natural Selection, $2.00.
The Population of an Old Pear-tree, $1.75.
The Private Life of Galileo, $1.50.
Yonge's English-Greek Lexicon, $7.00.
Cocker's Christianity and Greek Philosophy, $2.75.
March's Anglo-Saxon Grammar, $2.50.
Abbott's History of Hortense, $1.20.
Smiles's Self-Help, $1.00.
Phin's Chemical History of the Six Days of Creation, $1.00.
Journal of the Gynæcological Society, Vols. I. and II., $2.50 each.

ATOMS.

The "sweet tooth" of the world demands an annual supply of sugar amounting to 2,300,000 *tons*, of which Cuba furnishes fully one third. — Ozone may be easily prepared by blowing a current of air through a Bunsen flame into a large beaker. Its presence can be detected by its odor and the usual tests. — The sound of the human voice has been heard three miles over a level plain; a railroad whistle, eighteen miles; thunder, sixty miles; cannonading, eighty miles. — The fruit trade between the Mediterranean countries and New York now employs twelve steamers, of 1,250 tons each. — Baron Liebig has recovered from his late severe illness.—An effort is making to revive the cultivation of the mulberry in England for feeding silk-worms. — The oxy-hydrogen blowpipe is likely to become one of the "modern improvements" in burglary. — Prof. Andral has shown that infants have a lower temperature than adults only during the first half hour after birth. — Zinc is coming into use as a building material, not only for roofing, but for mouldings, etc., both interior and exterior. It is easily worked, and very durable, as the rust on its surface serves as a protection against further corrosion. — According to the testimony of druggists, there are at least one thousand habitual arsenic eaters in Cincinnati. — We are delighted to know that *jargonium* is not to be added to the jargon of chemical nomenclature as the name of a new element, the discovery having proved, like many others of the kind, to be all a mistake. — The first attempts at fire insurance in England were made in the reign of Charles II. — A sun-spot was observed not long ago which had eight times the surface of this planet of ours. — The Russian Government is about to establish an astronomical observatory on the summit of Mt. Ararat. An enthusiastic Englishman is trying to raise funds for an expedition to the same locality in search of relics of the ark. — Capers, after being pickled in salt water and vinegar, are sorted by means of sieves of copper wire, which improves their color, but makes them poisonous, like other "greening" processes of the kind. — They are laying pipes in Paris for the supply of oxygen. — The *Scientific American* is giving a valuable series of illustrated articles on insects, by E. C. H. Day, of the School of Mines, Columbia College. — The "dead weight" of a railroad train, in the way of engine, fuel, water, cars, etc., is from 1,300 to 1,500 lbs. for each passenger, even in a well-filled train; and the great practical problem of the day is how to reduce the enormous amount.— In the month of June, a fire occurred in the Forest of Fontainebleau, near Paris, sweeping over hundreds of acres. — Some 3,000 dwellings are vacant in Montreal, and eighty-seven French families recently left the city for the States in a single week. — At the Oregon State Fair a Chinaman did the best ploughing that was done on the grounds. — During the month of April more than $15,000 worth of fish spawn was exported from New York to England, Scotland, and France; and silk-worm eggs worth $660 were sent to the last named country. — Ohio has made stringent laws against the sale of dangerous kerosene, the seller of the oil being liable to punishment for manslaughter if death results from violation of the statute. — A piece of vegetable charcoal laid on a burn soothes the pain, and if kept applied for an hour cures it completely. — Mexico promises to become a coffee-raising country.

☞ SOME of our old subscribers have not yet informed us whether they desire to renew their subscriptions. If they do, will they please make it known to us by remitting the amount for Volume V.? The receipt of the money will be duly acknowledged in the usual way.

THE IMPROVED FURNACE. — From the tenor of the letters which come to us from all parts of the country, relating to the furnace recently described in the JOURNAL, we fear that our position in regard to it is not sufficiently well understood by our readers. We have distinctly stated that the improvements are for the benefit of the public, and every one is at liberty to avail himself of the advantages which are combined in the furnace. We cannot manufacture or supply it. Our duties are sufficiently numerous and exacting, without assuming any others at present. As regards the making of the furnace at different points in the country, it may be impossible, or impracticable. Small stove manufacturers have not the skill or the facilities to construct it, as it should be constructed, and the large houses, for the most part, have some device of their own which they are anxious to force upon the attention of their customers, as such usually pay large profits. As it is not for the interest of the large stove and furnace makers to have a simple and cheap device become popular, our readers must not expect such to speak approvingly of the furnace. A reliable stove manufacturing house in a neighboring city informs us that they have had patterns made with great care, and will soon have the furnace on exhibition and sale in this city. If it is well made, we will inform our readers, in the next number of the JOURNAL, where it can be procured.

ANSWERS TO CORRESPONDENTS.

☞ Questions pertaining to *all departments of the paper* — home science, arts, agriculture, medicine, etc. — will be answered under this head, but *only when the subject is one of general interest to our readers.*

D. S., UTICA, N. Y. We regard it as a vulgar notion that it is more healthful to sleep in a position with the head to the north. The whims and fancies which are started in the newspapers are endless, and for the most part hardly worthy of attention.

T. G. G., NORWAY, ME. You ask how to reclaim a wet meadow. If it is a bog, dig out the old roots and hassocks, pulverize the peat or muck as well as you can, drain it, and then cover it with a coating of sand from one to three inches deep. The best fertilizer is ashes, or ashes and bone flour, 500 lbs. to the acre. If you can procure "fish pomace," apply half a ton to the acre: we have found it to be excellent upon reclaimed meadows.

C. H. W., BOSTON. You cannot well restore rancid butter to a state of sweetness. It can be improved by the use of various agents, but the delicate sweetness, once lost, can never be restored.

J. H., PROVIDENCE, R. I. The best substitute for barn yard manure, for top dressing for moist grass lands, cheapness being considered, is a compost made of dry "fish pomace," with gypsum, or plaster. To a cord of good loam or soil add 200 lbs. of the fish pomace and 3 bushels of plaster; allow it to ferment well after mixing, and apply in the autumn. This affords splendid results.

D. G., BRYANTSBURG, IND. The most ready way of making the bones available, is to convert them into superphosphate by first burning them in a kiln to whiteness, grinding them in a plaster mill, and then dissolving the powder in sulphuric acid, after the method described in former numbers of the JOURNAL.
